CHEMICAL ABSTRACTS

Vol. 34) JANUARY 10, 1940 No. 1

—APPARATUS, PLANT EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

Laboratory equipment of the Division of Chemistry, National Research Laboratories, Ottawa, Canada. F. G. Cullen. *Can. Chem. Process Inds.* **23**, 525–4, 596, 528 (1939). W. H. Boynton 3

Substitute for laboratory oil baths. Averett A. Morton. *Ind. Eng. Chem. Anal. Ed.* **11**, 592(1939). —The advantages of using thick Al pots for air baths, in place of oil baths, are pointed out. H. A. Frediani

Small corrosion-proof laboratory pump. Geo. N. Gleason. *Chemist Analyst* **28**, 69–70(1939). —A pump suitable for handling corrosive liquids is described. Details are given for constructing the pump with a piston of 1-in. diam., a stroke of 1.5 in. which will deliver 23.5 l. per hr. against a 5.5-foot head. W. T. L. 4

Simple filtering apparatus for filtering and washing precipitates upon a microscope slide. H. Jurany. *Mikrochemie* **27**, 185–8(1939). —In a narrow glass tube of 1.5–2-mm. inside diam. an asbestos filter is placed between layers of fritted glass. One end of the filter tube is preferably attached to a glass stopcock which is connected with a water pump. To filter a soln. which is on a slide, it is merely necessary to place the filter tube in contact with the liquid and suck up the liquid. None of the ppt. will get by the filter. The ppt. can be washed in the same way and eventually dissolved and subjected to further examn. W. T. H. 5

An analysis of recent filtration equations—filtration at constant pressure. M. G. Lambert. *Trans. Am. Inst. Chem. Engrs.* **35**, 623–34(1939). —Two filtration equations which were proposed in recent years are compared. It is shown that the difference between the 2 is in the fact that a small correction to be added to observed time is indicated by the one while it is discarded by the other in an implied manner. It is, therefore, possible to reduce both to a mathematically identical form representing the equation of a section of a parabola. Reasons are given to show that both equations are inadequate in many cases, and based upon results obtained in calcg. industrial filtration problems by the use of these as well as of the equation $V = K\theta$, the adoption of the latter is recommended. C. L. Mantell 6

An improved device to demonstrate the laws of frequency distribution—with special reference to liquid flow in packed towers. R. S. Tour and Frank Lerman. *Trans. Am. Inst. Chem. Engrs.* **35**, 709–18(1939). —A new type of instrument for experimentally demonstrating and studying the laws of probability and frequency distribution is described. It is compared in construction and accuracy with the Galton type of instruments previously used for similar exptl. purposes and its inherent advantages over the other instruments are indicated. Data and sample curves are included that show the accuracy with which this new type of instrument approaches the theoretical laws of distribution. The instrument has been found effective in investigations of the underlying principles of bounded and unbounded distribution of liquid over tower packing, and it has possibilities in other lines of research involving the laws of frequency distribution. C. L. Mantell 7

The unconfined distribution of liquid in tower packing. R. S. Tour and Frank Lerman. *Trans. Am. Inst. Chem. Engrs.* **35**, 719–42(1939). —In developing the problem of liquid distribution in packed towers, distinction is made between unconfined distribution and confined distribution. Only unconfined distribution, in which no boundary or wall effect appears, is here considered. The phys. conception of liquid as made up of a no. of portions or streams, each of which flows from a point source and follows a tortuous path down through the packing of a tower, permits the application of the Laws of Probability (or of Frequency Distribution). From the Normal or Gaussian Law, as an approximation of the Binomial Law of Probability, equations are evolved expressing the liquid distribution as functions of the horizontal displacements of the liquid from the vertical center line of flow. The consts. of the equations are interpreted in terms of the phys. dimensions of the packing. Exptl. data are presented as obtained in a research conducted by Hurter in 1893 and the Laws of Probability are shown to hold. Tests by the authors on a coke-packed exptl. tower, 20 in. in diam., are also offered to prove the applicability of the probability equations. C. L. Mantell 8

The distillation industry in the last century. The origin of the continuous column. G. DuBois. *Rev. gén. applications ind.* **1939**, 20 pp.(reprint). E. H. 9

A distillation capillary. Alexander O. Gettler. *Ind. Eng. Chem., Anal. Ed.* **11**, 559(1939). —Sudden violent ebullition in the distn. capillary previously described (*C. A.* **33**, 7150[8]) is avoided by insertion of asbestos fibers in the larger capillary about 1 cm. from the end and tapping them down into the bulb after it is blown. Roster Dee Snell

Microchemical technique. III. Semimicro preparation and purification of organic substances. Geo. F. Wright. *Can. J. Research* **17, B**, 303–7(1939); cf. *C. A.* **32**, 1518[8]. —Several devices convenient in semimicro prepn. and purification of org. substances are described. A modified side-arm test tube is suggested as of general utility in microchem. lab. technique. J. W. Shipley 10

Clarification of liquids. I. Why small impurities produce big effects. Jerome Alexander. *Glass Packer* **16**, 699–700, 717–18(1937). **II. Causes and cures for cloudy liquids** *Ibid.* 762–4. **III. Facts about settling and straining.** *Ibid.* **17**, 41–4. **IV. Preparing liquids for clarification.** *Ibid.* 179–80, 190. **V. Filter aids, equipment, centrifugals and centrifuges.** *Ibid.* 302–3, 310. C. R. Fellers 11

Graphical solution of problems in multicomponent fractionation. Frank J. Jenny. *Trans. Am. Inst. Chem. Engrs.* **35**, 635–77(1939). —A new design method is presented for the complete solution of problems in multicomponent fractionation. The method is based on a graphical solution which is comparable in simplicity to the McCabe and Thiele method (cf. *C. A.* **19**, 1970) for binary mixts. In addn. to the graphical detn. of the no. of trays, the method inherently offers a simple means for detg. a suitable design reflux ratio. C. L. Mantell 12

An empirical relationship between reflux ratio and the number of equilibrium plates in fractionating columns. Geo. G. Brown and Homer Z. Martin. *Trans. Am. Inst. Chem. Engrs.* **35**, 679–708(1939); cf. preceding abstr. C. L. Mantell 13

Automatic absorption gas analyzers. M. M. Kalnberg. *Zavodskaya Lab.* **8**, 255–67(1939). —Various types of analyzers used in the Soviet Union are described and their uses and limitations are pointed out. B. Z. Kamien 14

Attachment for avoiding the sucking over of liquid in the micro-Kjeldahl apparatus of Parnas-Wagner. P. E. 15

...dahl. *Mikrochemie* 27, 195–6(1939).—The attachment serves to equalize the pressure during the steam distn. which removes the NH_3 from the reaction vessel to the receiver. It consists of a U-tube closed at both ends with rubber stoppers. On one side it is provided with a narrow tube which permits the withdrawal of liquid from the U-tube. One arm of the U-tube has the rubber stopper fitted with glass tubing covered with rubber tubing at the top and with a pinch cock, directly under the intermediate tube of the Parnas-Wagner app. The stopper of the other arm carries a long piece of tubing which reaches from near the bottom of the U-tube to a height of about 100 cm and at the top is fastened to an S-shaped bulb tube into which a few drops of dil. H_2SO_4 is placed. W. T. H.

Notes on the treatment of small precipitates. An improved filter and a small precipitating vessel. J. Donau. *Mikrochemie* 27, 189–94(1939).—An efficient filter which weighs only about 1 g. was prepd. by Heraeus from perforated Pt foil and compressed Pt sponge. When working with small quantities of liquid, a very shallow Pt dish is used; this is placed on the filter and is weighed with it. The dish is so shallow that it empties automatically. If larger quantities of liquid are to be handled, or if gaseous precipitants are used, a small cylindrical tap funnel is used instead of the small dish and pptn. takes place in this. The filtration is then accomplished by allowing the liquid to drop on the filter. The old trick of using a small trimmed feather is recommended for the complete removal of all ppt. from the tap funnel and its stem. W. T. H.

Organic chemical operations with small quantities of material. J. Erdos. *Mikrochemie* 27, 211–15(1939).—A review of app. suitable for distn., filtration and extn. of small quantities of material. W. T. H.

Electrolysis outfit. M. Ralph Berke. *Chemist Analyst* 28, 65–6(1939). A satisfactory app. for electroanalysis can be put together at a cost of less than $10. W. T. H.

A four-filter photoelectric colorimeter. B. T. Barnes. *J. Optical Soc. Am.* 29, 448–52(1939). E. H.

Novel metal membranes. A. Brendlin. *Arch. Wärmewirt.* 20, 207–8(1939).—The usual concentrically corrugated plate is made applicable to high pressures by backing it with a support (not attached to it) consisting of concentric rings of semicircular cross section, and a plate which may be segmentally split. Applications to heat-exchanger heads, expansion joints and valve-stem packing are shown. Ernest W. Thiele

Mercury vapor detector. Thomas T. Woodson. *Rev. Sci. Instruments* 10, 308–11(1939); cf. *C. A.* 33, 7622[8]. J. E. D.

Investigations on swing-mills [vibrating mills]. Robert Meldau. *Z. Ver. deut. Ing., Beiheft Verfahrenstech.* 1939, 95–8.—Expts. were made in an attempt to shorten the grinding period and to find the lower limit of fineness. Mills having capacities of 0.3 to 6 l. were used with a frequency of 1500 vibrations per min. and an amplitude of 3 mm. The effects of shape of grinding space and type of grinding balls are discussed. A no. of characteristic fineness curves for various materials and varying grinding periods are shown. Photomicrographs of surfaces of porcelain and glass balls are presented. A theoretical discussion of the grinding mechanism is included. It was possible to establish the presence of fields in the mill which favor extremely fine grinding but a lower fineness limit could not be established. 10 references. Karl Kammermeyer

Comparative grinding tests on crystalline and amorphous quartz; grain distribution and grain forms. K. Wolf, H. Hennicke and A. Smekal. *Z. Ver. deut. Ing., Beiheft Verfahrenstech.* 1939, 119–29.—Cryst. and amorphous quartz under identical grinding conditions give products with identical grain-distribution curves and grain forms. Graphs, photomicrographs and 3 references are given. Karl Kammermeyer

An adiabatic high-temperature calorimeter for the determination of heats of reactions occurring in the formation of alloys. O. Kubaschewski and Alexander Walter. *Z. Elektrochem.* 45, 630–6(1939).—There is described an adiabatic calorimetric system, applicable up to 700°. It consists of (1) the calorimeter proper, constructed of Ni-Cr steel, holding a reaction crucible of Fe or graphite; (2) a heating jacket, also of Ni-Cr steel, wound with a Ni-Cr heating coil; and (3) an enclosing thermostat of asbestos, contg. a heating coil. Thermal equil. between the calorimeter and the jacket is detd. by means of a Ni-Cr thermoelement. Any const. difference in temp. is minimized by an asbestos baffle placed over the heating jacket. The temp. rise of the calor meter is measured by means of a Pt resistance thermometer wound around the calorimeter. The energy equiv. was detd. by the method of mixt., with a Ni sphere. This was checked by detg. the known heats of formation of $MgBi_2$ and $CaAl_2$. The estd. uncertainty of the results is ±2.5%. J. W. Knowlton

A new vacuum adiabatic calorimeter. A. B. Adams, R. S. Brown, V. H. Barnes and O. Maass. *Can. J. Research* 17, B, 41–52(1939).—A new adiabatic calorimeter is described in which transfer of the material under investigation from the thermostat to the calorimeter is effected through an evacuated space. The liquid used in the calorimeter is Hg. An accuracy of better than 0.05% is claimed. J. W. Shipley

Research problems in drying technique. Karl Kröll. *Z. Ver. deut. Ing., Beihft. Verfahrenstech.* 1939, 43–5.—A discussion. Karl Kammermeyer

Solvent extraction and absorption. Werner Mathis. *Z. Ver. deut. Ing., Beiheft Verfahrenstech.* 1939, 76–85.—A graphical solution is shown for the system methylcyclohexane–$NH(CH_2)_6$–C_7H_{16}. Mass transfer at a liquid interface, absorption of CO_2 in H_2O and recovery of H_2S from waste gases are also treated. Data, diagrams and 14 references are given. Karl Kammermeyer

Vacuum-pan design. Colin W. Waddell. *Sugar News* 20, 51–5(1939).—Mech. improvements. W. W. B.

Stability of the distribution of flow in heating surfaces with forced circulation. A. Kleinhans. *Arch. Wärmewirt.* 20, 135–8(1939).—K. discusses mathematically the conditions under which parallel tubes in which liquid is vaporized will tend to take unequal amts. of flow. Ernest W. Thiele

Heat transfer in the radiant section of petroleum heaters. Walter E. Lobo and James E. Evans. *Trans. Am. Inst. Chem. Engr.* 35, 743–78(1939).—A brief review of empirical equations for predicting heat transfer in the combustion chambers of steam boiler and petr. heaters is followed by a study of 85 performance tests on 19 furnaces differing widely in amt. and arrangement of refractory and cold surfaces. Operating conditions are available on furnaces with and without air preheat, with and without flue-gas recirculation, fired with refinery cracked gas or oil fuel, and with a wide range of variation of excess air. The data are correlated by means of a theoretical equation and the deviations are no greater than the probable errors in the test data, and consistently less than those obtained by the empirical equation of Wilson, Lobo and Hottel (*C. A.* 26, 3311). For simplicity of calcn. the equation is presented in graphical form. An illustrative design problem has been included. C. L. Mantell

Contact furnaces and contact equipment in the chemical industry. W. Klempt. *Z. Ver. deut. Ing., Beiheft Verfahrenstech.* 1939, 122–7.—A discussion of the most important types of equipment for catalytic gas reactions with figures and 12 references. Karl Kammermeyer

Computing heat transfer by radiation from flue gas to heating surface. Josef Böhm. *Arch. Wärmewirt.* 20, 209–12(1939).—Charts to facilitate the calcn., based on recent literature, are given. Ernest W. Thiele

Computing flue-gas cooling in water-tube boilers. Alfred Becker. *Arch. Wärmewirt.* 20, 237–9(1939).—Charts for calcg. final flue-gas temp. (const. or variable water temp. is assumed) are presented. E. W. Thiele

The cooling of flue gas in water-tube boilers. Josef Böhm. *Arch. Wärmewirt.* 20, 75–8(1939).—B. presents charts to reduce the trial and error necessary in calcg. heat transfer in boilers. Ernest W. Thiele

An efficiency meter for boiler plants. J. Köchling. *Arch. Wärmewirt.* 20, 169–72(1939).—The flue-gas quantity is measured by a large-flow nozzle in the breeching, and a delicate manometer. The temp. is also meas-

ured. Steam flow is measured with a flow meter. Radiation and combustible losses, and total heat of steam, are assumed const. The calcn. is made electrically and recorded. Two com. installations are operating well.
Ernest W. Thiele

The limits of furnace load and their influence on boiler design. W. Pauer. *Arch. Wärmewirt.* 20, 197–202 (1939). The factors which affect the max. heat release per unit furnace vol., and their relations, are discussed.
Ernest W. Thiele

The character of the valves developed under the influence of hot high-pressure steam. M. Kyöleln. *Arch. Wärmewirt.* 20, 241–5(1939).—In addn. to various mech. features, the resistance to rubbing of various materials for valve seats is discussed. An app. was used in which a known pressure and temp. were applied to a flat ring of the metal, and the no. of rotations before seizure was noted. At 450° nitrided steel was by far the best; stellite was fair. At low temps. bronzes are suitable. Stainless steels are poor.
Ernest W. Thiele

Brines in air conditioning. Adjusting concentrations with chemical dehumidifiers. Stewart C. Coey. *Ice and Cold Stor.* 42, No. 491, 71–2, 76 (1939); cf. *C. A.* **33**, 6091⁵.
A. H. Johnson

Freezing mixtures. L. L. Woods. *Chemist Analyst.* 28, 64–5(1939).—Freezing mixts. are given suitable for cooling to −100°.
W. T. H.

Shell for pressure-extraction apparatus. Joseph D. Christian. U. S. 2,170,547, Aug. 22. Various details of app. suitable for pressing juices from fruits, oils from fish, etc.

Apparatus for testing magnetizable workpieces. Friedrich Jahne (to I. G. Farbenind. A.-G.). U. S. 2,170,371, Aug. 22. An app. for detecting inhomogeneities in magnetizable work pieces, such as welded seams, comprises a ferromagnetic core encircled by a coil, mech. means for moving the core in an eccentric manner and a listening device connected to the coil which indicates the voltage induced in the coil if the coil passes inhomogeneities in the work piece parallel to the surface of which it is moved.

Separatory flask suitable for use in analytical work, for extracting alkaloids, etc. Morris B. Jacobs and Alexander A. Singer. U. S. 2,170,411, Aug. 22. Various structural details.

pH comparators. Donald K. Allison (to National Technical Laboratories). U. S. 2,172,352, Sept. 12. A method of preparing a comparator for use in pH detns. with a particular indicator dye having various color and intensity transmission characteristics at various pH values in soln. comprises: detg. the spectrum-transmission characteristics of a soln. of such a dye at numerous selected pH values throughout the pH range thereof; photographically exposing a photosensitive surface on an elongated transparent member and dye-toning the surface in such manner as to produce a dye-image on the member, of graded intensity, and having various color-transmission characteristics along its length in accordance with the spectrum-transmission characteristics of such indicator dye soln. at the various pH values. Various examples and details are given.

Spherical metal containers such as those for holding carbon dioxide and the like under high pressure. Walter H. Freygang (to Walter Kidde & Co.). U. S. 2,171,111, Aug. 29. Various mfg. details.

Filters. Jacques Muller. Brit. 507,286. June 13, 1939. In a filter element built up of alternate filtering-disks and resilient impermeable clamping disks, the latter are each formed with 2 annular projections and 2 annular depressions, which form bearing surfaces for the adjacent disks.

Filters, e. g., for the filtration of liquids or gases. Philip G. Marr and Yokes Ltd. Brit. 507,762, June 19, 1939. A filtering element is formed of flexible material with radial folds or pleats and with other folds transverse thereto. Filters contg. the elements are described.

Filter-impregnating apparatus. Frank B. Hale and Frank A. Logan. U. S. 2,170,142, Aug. 22. Various details of an app. suitable for impregnating gas and smoke filters with lampblack, etc.

Filter for use in hot-air furnace conduits. Robert L. Kennedy. U. S. 2,171,797, Sept. 5. Various structural details.

Filtering unit for incorporation in a plate-type heat exchanger. Richard Seligman, Hugh F. Goodman and The Aluminium Plant & Vessel Co. Ltd. Brit. 505,698, May 16, 1939. The unit includes a frame forming, with one or more filtering elements, a chamber for the filtered liquid or the liquid to be filtered, and provided with ports for the passage of a heating or cooling liquid.

Gravity-seperation apparatus. Horace Freeman. Brit. 507,412, June 13, 1939. To separate heavier matter from a liquid, e. g., a suspension of paper pulp or china clay, the liquid is introduced under pressure from a pipe through a tapered nozzle into a spiral channel surrounding an outlet tube in a receptacle, so that it is caused to flow downspirally in the outer portion of the vessel and the heavier matter is sepd. centrifugally. From the lower end of the receptacle the suspension of the lighter matter rises, still moving spirally, as a central core and passes away through the outlet tube.

Washing gases. Arthur Ryner. Brit. 506,405, May 26, 1939. Dust and fumes are removed from gases by passing them in a helical path to remove large particles centrifugally and then bubbling them through a liquid to which a wetting agent, e. g., oil, may be added, to remove fine particles. App. is described.

Apparatus for separating gases such as oxygen and nitrogen by centrifugal action. Emery C. Furrer. U. S. 2,170,071, Aug. 22. Various structural and operative details.

Gas analysis. Wm. J. Sweeney (to Standard Oil Development Co.). U. S. 2,170,435, Aug. 22. App. is described, and a process for detecting minute amts. of C_2H and higher hydrocarbons in soil gases by subjecting the gas to combustion, passing infrared rays through the combustion products and observing the amt. of energy absorbed from a band of rays from which CO_2 has the power to absorb energy.

Cell for analyzing gases by the heat-conductivity method. Wm. G. Gow (to Gow-Mac Instrument Co., a partnership). U. S. 2,171,502, Aug. 29. Various structural details.

Gage for measurement of gas pressure. Samuel Palkin and Thomas C. Chadwick (to the People for free use). U. S. 2,169,812, Aug. 15. Various details of a vacuum gage.

Apparatus for measuring and regulating the viscosity of a fluid. The British Thomson-Houston Co. Ltd. Brit. 506,172, June 6, 1939.

Apparatus for bringing liquids into contact with gases especially for cooling one of them. Heenan & Froude Ltd. and Geo. H. Walker. Brit. 505,590, May 15, 1939. The app. comprises several flat plates or strips, preferably of metal, each with conical or pyramidal protuberances pressed or punched out at intervals, the sides of the protuberances being split to form comparatively sharp projections against which the gases strike when flowing over the surface, turbulence being thereby promoted.

Liquid-spray gas-treatment apparatus, suitable for treating air with calcium chloride solution, etc. Harry A. Wintermute (to Research Corp.). U. S. 2,172,304, Sept. 5. Various structural and operative details.

Apparatus for treating liquids with gases (as in treating water with bottles with carbon dioxide). Roger E. Roth (to Société d'étude pour l'acide carbonique). U. S. 2,172,033, Sept. 5. Various structural and operative details.

Apparatus for dispensing liquids such as gasoline or oils. Joseph A. Logan and Warren H. DeLancey (to Gilbert & Barker Mfg. Co.). U. S. 2,171,707, Sept. 5. Various structural and operative details.

Apparatus for heating liquids, e. g., liquid bitumen. T. Sugden Ltd. and Albert Hall. Brit. 506,392, May 25, 1939. The liquid is progressively heated while passing through a tank by superheated steam or other vapo

flowing through serially connected tube coils with intermediate resuperheaters in sep. furnaces.

Float-valve device for use in metering liquids such as fuel oil. Charles K. Bassett. U. S. 2,171,620, Sept. 5. Various structural, mech. and operative details.

Filtering material suitable for use in purifying liquids such as oils or sugar solutions. Stansbury M. Wilson and Wm. H. Waggaman (to Baugh & Sons Co.). U. S. 2,171,601, Aug. 22. A filtering material is prepd. by adding to finely divided phosphatic material, such as ground phosphate rock, a carbohydrate binding material such as starch, glue or molasses and NH_4 phosphate and gradually heating the mass to a temp. sufficiently high (suitably about 500°) to char the carbohydrate binding material and decompose the NH_4 phosphate.

Subjecting liquids to sound vibrations, for homogenizing milk, preparing emulsions, etc. Robert L. Williams (to Submarine Signal Co.). U. S. 2,170,178, Aug. 22. Various details of app. and operation.

Taps for containers such as those for holding liquefied propane and butane. Rosswell W. Thomas (to Phillips Petroleum Co.). U. S. 2,172,310-11, Sept. 5. Various structural details.

Pilot valve for controlling the level of liquids in tanks. Jean E. Christian (to Phillips Petroleum Co.). U. S. 2,171,394, Aug. 29. Various structural, mech. and operative details.

Intermittent control device suitable for controlling the flow of well fluids. Jeddy D. Nixon (50% to Wilson Supply Co.). U. S. 2,171,812, Sept. 5. Various structural and operative details.

Apparatus for atomizing liquids such as lubricating oils for pneumatic tools. Harold Holmboe and Andy B. Cosper. U. S. 2,171,932, Sept. 5. Various structural details.

Liquid-cooling apparatus, suitable for cooling water without freezing. Arthur R. Brown (to Westinghouse Elec. & Mfg. Co.). U. S. 2,171,740, Sept. 5. Various structural and operative details.

Apparatus for filling containers such as bottles with liquid soap compositions. Stanley R. Howard (to Pneumatic Scale Corp.). U. S. 2,172,132, Sept. 5. Various structural, mech. and operative details.

Separating solids from gases. John E. Fulweiler. U. S. reissue 21,185, Aug. 29. A reissue of original patent No. 2,076,815 (*C. A.* **31**, 3746[8]).

Drying apparatus for warps or like materials. Robert W. Moncrieff and Percy H. Miller (to Celanese Corp. of America). U. S. 2,171,731, Sept. 5. Various structural, mech. and operative details.

Apparatus for drying leather, lumber, hair felt, paper, rubber, etc. John B. Ohlson (to Ira M. Jones). U. S. 2,170,763, Aug. 22. Various structural and operative details.

Furnaces. John S. Zink. Brit. 506,509, May 30, 1939. An oil burner and a gas burner are so mounted in a furnace for heating stills, etc., that either can be removed without disturbance of the operation of the remaining burner.

Soaking-pit furnaces. Stein & Atkinson Ltd. and James S. Atkinson. Brit. 506,440, May 30, 1939. The cover of a soaking-pit is rotatably mounted on rollers, which move on a runway, and carries at its outer end a plate, which depends and moves in a trough containg. sand. The cover is provided with an aperture which is closed by a lid provided with a sand and other seal.

Pit-type reheating furnaces. Charles F. Forest. Brit. 505,790, May 17, 1939. They have regenerators at opposite sides and inlet and outlet ports at different levels and so arranged that the heating gases traverse the heating chamber in horizontal streams adjacent the side walls.

Portable heating furnace utilizing oil or gas, etc., as fuel. Raymond B. Millard. U. S. 2,171,941, Sept. 5. Various structural details.

Water cooled tuyères for shaft furnaces. H. A. Brassert & Co. Brit. 506,622, June 1, 1939.

Apparatus for the automatic charging and discharging of a rotary-hearth furnace. Olga Ehrendorff. Brit. 506,144, May 23, 1939.

Fans for circulating the atmospheres of furnaces through different paths. James Macdonald and G. W. B. Electric Furnaces Ltd. Brit. 507,545, June 15, 1939. Divided on 497,480 (*C. A.* **33**, 3745[9]). The fans are movable axially to any one of a no. of positions, in each of which they cooperate with appropriate ducts for a given path, while the ducts corresponding with the other paths are obturated to prevent circulation therethrough.

Burners such as Bunsen burners. Harry M. Ullmann. U. S. 2,171,816, Sept. 5. A metal gas-inlet tube is attached to the burner which has sufficient length that the heat which is transferred to it when the burner "strikes back" is dissipated so as not to damage a connected rubber gas-supply tube.

Blowpipe burners. I. G. Farbenindustrie A.-G. Brit. 506,504, May 30, 1939.

Apparatus for separating suspended particles from furnace fumes by baffling and centrifugal action. Leon Thuillard. U. S. 2,172,133, Sept. 5. Various structural and operative details.

Apparatus for various heat treatments. Geo. E. Markley. U. S. 2,171,340, Aug. 29. Various structural, mech. and operative details.

Heat-exchange apparatus (with adjacent spaced plates) suitable for heating air, etc. Emile Prat. U. S. 2,170,484, Aug. 22. Various structural details.

Straight-tube heat-exchangers. John R. Rylands Brit. 507,995, May 15, 1939.

Apparatus for producing smoke by spraying oil, with or without color and in the presence of a strong current of air, against a heated surface. Thomas M. Kinnear. Brit. 506,159, May 24, 1939.

Air cleaner, for liquid treatment and filtration. Herbert G. Kamrath (to General Motors Corp.). U. S. 2,171,752, Sept. 5. Various details of air cleaners suitable for use with internal-combustion engines.

Homogenizing various pulverulent materials by use of air currents. Edouard Hastert. U. S. 2,171,998, Aug. 29. Various details of app. and operation are described by this patent and by U. S. 2,171,399 (Edouard Hastert (to Louis Peters)).

Apparatus for heating, cooling, kneading, grinding and emulsifying materials such as in margarine manufacture. Lars K. V. Holstrup. U. S. 2,170,303, Aug. 22. Various details of an app. with coacting helically grooved rollers.

Rotary hammer mill for comminuting grain, stocks, seed minerals, etc. Theodore C. Alfred. U. S. 2,172,096, Sept. 5. Various structural, mech. and operative details.

Ball and tube mill for grinding various materials. Georg H. Schierstein. U. S. 2,170,768, Aug. 22. Various structural, mech. and operative details.

Hammer mill suitable for grinding grains, coal, rock, etc. John A. Erickson. U. S. 2,169,681, Aug. 15. Various structural and operative details.

Attrition mills for pulverizing ores, cement, rock, clay, etc. George A. Ainsa (in part to Dolores Ainsa). U. S. 2,171,523-6, Sept. 5. Various structural, mech. and operative details.

Mill with a reciprocating size-reducing chamber suitable for continuous operation in the treatment of ores, coal, cement clinker, etc. Louis A. Maxson (to Sullivan Machinery Co.). U. S. 2,171,515, Aug. 29. Various structural, mech. and operative details.

Apparatus for classifying metal-bearing sands, ores, etc., by flowing water. Charles J. Schifferle (50% to Walter W. Jolliffe). U. S. 2,171,674, Sept. 5. Various structural, mech. and operative details.

Apparatus for reclaiming ore, etc., from storage piles. Morris J. Andrada (to Robins Conveying Belt Co.). U. S. 2,171,528, Sept. 5. Various structural mech. and operative details.

Pressure vessels of material such as welded sheet metal and comprising interconnected hollow spheres. Hermann Dibor (to Dominion Oxygen Co., Ltd.). U. S. 2,171,972-3, Sept. 5. Various structural and mfg. details.

Piston valve for high-pressure reaction vessels. Joseph L. Stecher and Herbert H. Parker (to E. I. du Pont de

Nemours & Co.). U. S. 2,170,353, Aug. 22. Various details of app. suitable for rendering fats or for various chem. reactions.

Safety can for holding and pouring naphtha or other combustible or explosive liquids. Wm. A. Lebus (to Protectoseal Co. of America). U. S. 2,172,142, Sept. 5. Various details of pouring spout and vent construction, etc.

Cutting torch or blowpipe supplied with gas and oxygen Charles F. Carroll. U. S. 2,170,793, Aug. 29. Various structural and operative details.

Apparatus for preheating wet material such as gut strings. Lloyd E. Dimond (to Wilson & Co.). U. S. 2,170,747, Aug. 22. Various structural, mech. and operative details.

Capillary tube and bulb for thermostatic controls. Francis W. Sullivan (to United Wire & Supply Corp.). U. S. 2,170,612, Aug. 22. A method of forming a capillary tube and bulb for a thermostatic control involves reducing the diam. of a tube of relatively large size for a portion of its length to capillary size, leaving the other portion larger, and deoxidizing and dehydrating the entire surface of the unit so formed for its entire length.

Measurements of pH in the Atlantic and Pacific Oceans. Jules Rouch. *Compt. rend.* **209**, 634-5(1939).—Detn. of the pH of surface sea water on a voyage from Havre to San Francisco via the Panama Canal showed a somewhat irregular increase as the latitude was lower, from 8.08 in 50° N to 8.27 in 10°, but an even higher max. (8.26) off the west coast of Mexico and Central America. C. A. Silberrad

Theory of rotation transitions. Klaus Schäfer. *Z. physik. Chem.* **B44**, 127-62(1939).—By assuming a common orientation of coupled rotators in the 2 lowest quantum states, a theory of rotation transitions is obtained which is similar to order-disorder phenomena in mixed crystals. It differs from the latter in the dependence of the energy on the degree of orientation, since this depends not only on the potential energy but also on quantum states and energy values. The theory explains the marked effect of CH_4 on the CD_4 transition (cf. *C. A.* **32**, 6536⁷) as well as various peculiar hysteresis effects which have been observed. G. M. Murphy

Bonds of large molecules. Constantinos Askitopoulos. *Chim. Chronika* (Greece) **4**, 167-74(1939)(in Greek).—Lecture. Lucien V. Dyrenforth

Magnetism of chlorides of the palladium and platinum triads of elements. B. Cabrera and A. Duperier. *Proc. Phys. Soc.* (London) **51**, 845-58(1939).—The magnetic susceptibilities of $RhCl_3$, $OsCl_3$, $IrCl_3$ and $PtCl_2$ were measured by the torsion balance method, with electromagnetic compensation, over a range of approx. 300°, starting at room temp. The results for $RhCl_3$ agree with those previously obtained by C. and Fahlenbrach (cf. *C. A.* **29**, 2410⁵), and the results for all the cations can be represented by an equation of the form $(\chi + K)(T + \Delta) = C$. Expt'l. details of the method and of the special electromagnet used are described fully. The theoretical interpretation of the results is discussed. W. W. S.

Paramagnetic relaxation in gadolinium sulfate. W. J. de Haas and F. K. du Pré. *Physica* **6**, 705-16(1939)(in English).—A mutual inductance bridge is described by which the differential susceptibility of very pure cryst. $Gd_2(SO_4)_3.8H_2O$ in an external magnetic field was detd. at liquid-He temp. The results agree with the theoretical predictions of Casimir and du Pré (*C. A.* **32**, 6918³·⁴) and others. The sp. heat of the spin system and the relaxation time of the spin-lattice equil. were calcd. from these data. For a field of 1350 oersteds, the relaxation times at 4.236°, 3.515° and 2.998° K. are 0.0038, 0.0060 and 0.0080 sec., resp., reliable to approx. 15%. W. W. Stifler

The effect of lattice disturbances on ferromagnetic properties. H. Schlechtweg. *Tech. Mitt. Krupp Forschungsber.* **2**, 163-6(1939).—The ferromagnetic condition of a material is discussed theoretically on the basis of the definition that in this condition every monocrystal of the material is subdivided into zones that are practically spontaneously magnetized to satn. The apparently nonmagnetic state is due to the facts that the different zones are magnetized in different directions and that a definite magnetic condition appears only if the exterior field is sufficiently strong to cause all individual magnetizations to coincide with the magnetizing field. The theoretical discussion and corroborating expts. show that in the proximity of a lattice disturbance the crystal lattice is

inhomogeneous, i. e., is deformed from place to place in different manner; and as no practical material is free of such inhomogeneities in the crystal lattice the magnetic condition changes with the deformities. A formula for the components of the deformation is derived. **Effect of mechanical stresses on ferromagnetic properties.** *Ibid.* 167-70.—The considerations of the previous discussion are extended to mech. stresses, as this might have practical importance, e. g., with steels used in electromagnetic arrangements and subject to stresses due to cold-deformation in operation (permanent magnets, high-permeability steels). The changes in the interior energy distribution of the crystal lattice by mech. stresses in the magnetic state are theoretically investigated. It is derived that a deformation in the crystal lattice leads to a shifting of the place of the energy of the wall sepg. 2 elementary zones, and to the assumption of the existence of one part of the magnetic field strength which is independent of magnetostriction and of the anisotropy of the crystal. Seven references. M. Hartenheim

The validity of the law of Curie for oxygen at high densities. Max Kanzler. *Ann. Physik* **36**, 38-46(1939). — Curie's law is valid for ds. below 0.12 g./cc. (corr. to 20°) at temps. from 290 to 625°K. The Curie-Weiss law is valid at ds. above 0.20 S. Bradford Stone

The velocity of sound in liquid argon. H. W. Liepmann *Helv. Phys. Acta* **12**, 421-42(1939). -The method of obtaining sound velocities in liquids by observing the diffraction of light by ultrasonic waves is adapted for liquid gases at low temp. The velocity v in A is 642 m./sec. at −186.5° and 867 m./sec. at −197° and changes linearly in the interval. For *liquid* N_2 the figures are 868 m./sec. at −197° and 929 m./sec. at −203°. The error is 0.5%. A discrepancy of 20% is found between the compressibility derived from these sound-velocity measurements and that obtained from purely thermal data, which is outside the exptl. error. E. B.

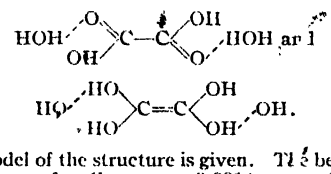
The properties of flow of liquid He II. J. F. Allen and A. D. Misener. *Proc. Roy. Soc.* (London) **A172**, 467-91 (1939); cf. *C. A.* **32**, 1995[2]. The hydrodynamic properties of liquid He II were detd. from measurements of flow through capillaries and fine powder. The flow through capillaries bears no resemblance to ordinary laminar or turbulent flow. The effects of temp., pressure and capillary dimensions were investigated. The results are interpreted in terms of 2 types of flow occurring together in the liquid: a surface flow along the walls independent of pressure and another, predominant in large capillaries, having a viscosity of order 10^{-4} c. g. s. units which increases with decreasing temp. H. C. Thomas

The electrical conductivity of thin films of mercury. E. T. S. Appleyard and J. R. Bristow. *Proc. Roy. Soc.* (London) **A172**, 530-9(1939). - The results of an investigation of the elec. resistance of Hg films deposited in high vacuum on surfaces at 20.4 90°K. indicate that the delayed appearance of cond. as deposition proceeds is due to agglomeration of Hg into solid droplets and that the sudden onset of cond. is due to the touching of these droplets. The temp. coeffs. are pos. and reversible. Films > 500 A. in thickness deposited at 90°K. or lower can be regarded as coherent slices of strained metal. H. C. Thomas

Electrical conductivity and diffusion in semimetallic alloys. IV. Electrical conductivity and thermal potential of α-silver sulfide. H. Remhold and Karl Schmitt. *Z. physik. Chem.* **B44**, 75-97(1939); cf. *C. A.* **33**, 2009[8].—The elec. cond. was measured as a function of S pressure and of temp. Absorption of S as a function of S pressure and temp. was also measured. The e. m. f. of the cell Pt(S)| T_1 α-Ag_2S|Pt(S), T_2 was measured at temps., T_1 = 400° T_2 = 350; 350, 300; 300, 250° and at S pressures between 0.3 and 83 mm. G. A. Murphy

A method for the determination of the rate of dissociation of sulfur vapor. H. Remhold and Karl Schmitt. *Z. physik. Chem.* **B44**, 98-108(1939).—The elec. cond. of α-Ag_2S in the presence of S vapor depends on the shape of the cond. vessel (cf. preceding abstr.). If free communication is permitted between the region contg. the liquid S and the region contg. Ag_2S, the cond. is greater than in a vessel where S vapor reaches the Ag_2S only through a capillary. The effect is shown to be due to the rate of dissocn. and recombination of S vapor. A streaming method is described for measuring both rates. The half-time is of the order of 1 min. G. M. Murphy

Superconductivity of thin films. I. Mercury. E. T. S. Appleyard, J. R. Bristow, H. London and A. D. Misener. *Proc. Roy. Soc.* (London) **A172**, 540-58(1939).—Hg films prepd. in high vacuum were examd. in the superconducting state. The transition temps. to the superconducting state of films previously annealed at 90°K. or higher are close to that of the bulk metal. Films deposited at 4.2°K. and not annealed show displacement of transition temps. downward by about 0.2°K. No evidence of variation of transition temp. with film thickness was found. Crit. longitudinal magnetic fields (H_t) required to restore normal cond. were studied at various temps. $H_t/H_m > 1$ and increases rapidly with diminishing thickness; H_t/H_m increases steeply at the transition temp. (H_m is the crit. field for bulk metal.) Conclusion: There is an increase in field penetration as the transition temp. is approached. H. C. Thomas



Principal piezoelectric modulus of quartz. André Langevin. *Compt. rend.* **209**, 627-8(1939).—The variations reported in the piezoelec. modulus of quartz, θ, ($4.94-7.18 \times 10^{-8}$) are due to the presence of twins with parallel optic axes, which are not detectable optically but only through the corrosion figures produced by, e. g., HF. When this cause of error is avoided, θ is found to be a true phys. const., roughly equal to 7.10×10^{-8}.
C. A. Silberrad

Modification of crystalline architecture by the action of weak torsion. R. Jacquesson. *Mécanique* **23**, 156-62 (1939).—X-ray patterns produced by a cylindrical crystal specimen of Al subjected to slight degrees of torsion, particularly 2°40', 4°, 5° and 6°, are quantitatively measured and interpreted. It is at once apparent that some planes in the crystal are more profoundly affected than others. The sharp cryst. interferences of the original Laue pattern are pulled out into elongated streaks in varying degree, depending upon the indexes of the planes, by an angular displacement of crystallites in a reticular layer of 45° with the axis of torsion. The results are considered in the light of several theories of deformation.
George L. Clark

Rotation of molecules in the crystal lattice. Chr. Finbak. *Arch. Math. Naturvidenskab* **B42**, No. 1, 71 pp. (1938).—The scattering of x-rays in a system of free electrons, atoms, homogeneous rotating and homogeneous free rotating mols., and of some phys. properties of crystals built up of rotating mols., i. e., thermal properties, dielec. const., deformability, and surface properties are discussed. In continuation of previous investigations on CBr_4, C_2Cl_6 and pentaerythritol (cf. *C. A.* **32**, 1996[5]) there are studied by means of Debye x-ray diagrams, the compds. from the camphor series *d,l*-camphene at about 20°, body-centered cubic, a about 8.00 A., 2 mols. per unit cell, *d,l*-camphor at 150°, a about 10.1 A., borneol at 190°, a about 10.25 A., and bornyl chloride at 110°, a about 10.39 A. The last 3 compds. can be represented best by a face-centered cubic lattice with 4 rotating mols. per unit cell (0,0, 0; ½, ½, 0; ½, 0, ½; 0, ½, ½). Succinic acid nitrile at ordinary temp. has a body-centered cubic lattice, a about 6.40 A., 2 rotating mols. per unit cell (0, 0, 0; ½, ½, ½). Strong blackening of the background was observed in all cases studied. The rotation of the mols. seems not to be completely free but to be coupled to a certain degree to that of other mols. Probably 2 mols. while rotating penetrate into their mutual rotation ranges. This is confirmed for CBr_4 and C_2Cl_6 by calcn. of the distance of the rotation center of one mol. from that of its closest neighbor. Debye diagrams of the compds. detd. directly below and above the m. p. show a great conformity. The arrangement of the mols. in the crystal powder and in the liquid at these temps. must be very similar. This can be explained either by assuming for the liquid a crystal-like structure being in a permanent change

or by attributing to it a compn. of small lattice ranges with a structure similar to that of the solid. G. N.

Studies of chemical bonds by means of Fourier analysis. III. The bond in quartz. R. Brill, C. Hermann and Cl. Peters. *Naturwissenschaften* 27, 676-7(1939); cf. *C.* 4. 33, 4675, 9062[8].—For study of the α quartz lattice a 1-mm. thick milk-quartz plate was used. In order to find electron-d. distribution it was necessary to have one Si-O bond in the projection plane; this is the case when the direction of the double axis is used, the angle between Si-O and the plane is only 30′ There were measured 470 reflexes of the *hOhl* zone, the quartz plate was ground corresponding to 1210. The results are shown of the electron-d. topography and a corresponding model diagram is given. The electron d. indicates that the bond between Si and O is such as would be expected if a spherical Si and a spherical O atom were set up at the specified distance, there is no electron excess at the "saddle point" such as is found in the diamond lattice. Conclusion: The Si-O bond is midway between hetero- and homo-polar. The parameters measured from the diagrams agree with the We[1] (*C. A.* 30, 2820[7]) data: $x_{Si} = 0.465$, $x_0 = 0.415$, $y_0 = 0.272$, $z_0 = 0.120$. P. **The oxygen bond in oxalic acid dihydrate.** *Ibid.* 677-8. Crystals of oxalic acid dihydrate sepd. from a soln. and grown as columns in the *b* axis direction were used for structure detn. About 250 reflexes of the *hOl* zone were used. The distance between C atoms is larger than found by Robertson and Woodward (*C. A.* 31, 1364[4]) probably because of a premature breaking of the Fourier series by them. With the R. and W. projection of zone *Okl* the at. distances found are C—C = 1.53, C—OI = 1.28, C—OII = 1.17, OI—H_2O = 2.51 and 2.96, OII—H_2O = 2.90 and 2.96. The C—C distance is normal; hence the "resonance structure" used by R. and W.[2] is incorrect. The present data indicate resonance of the 2 structures

A space model of the structure is given. The best parameter values are for C $x = -0.0014$, $z = 0.1014$, for OI $x = 0.1153$, $z = 0.1803$, for OII $x = -0.0903$, $z = 0.1634$, for H_2O $x = -0.1384$, $z = 0.4945$.
B. J. C. van der Hoeven

X-ray structure of potassium cupric bromide. Alfred Silberstein. *Compt. rend.* 209, 540-2(1939).—$KCuBr_3$, prepd. by evapg. in vacuum mixed solns. of KBr and $CuBr_2$, the latter in excess, crystallizes in very hygroscopic long thin (5 cm. × 1 mm.) needles. These are holohedral-monoclinic with *a* 4.28, *b* 14.43, *c* 9.71 A. β 108°23′, and 4 mols. in the unit cell, space group $C_{2h}^3(P2_1/m)$.
C. A. Silberrad

The crystal structures of rubidium and cesium sesquioxides. Alfred Helms and Wilhelm Klemm. *Z. anorg. allgem. Chem.* 242, 201-14(1939); cf. *C. A.* 33, 8073[9].—Studies of the higher oxides of the alkalies (cf. *C. A.* 33, 7640[4]) yielded several specimens whose compns., ds. and x-ray diffraction diagrams were consistent with the formulas, Rb_4O_6 and Cs_4O_6, resp. No K analog was encountered. Both are face-centered cubic, space group T_d^2 of the anti-Th_3P_4 type, with $a_0 = 9.30$ and 9.86, resp. Magnetic susceptibilities are consistent with a proportion of 2 O_2^- to 1 O_2^{--}. Twelve O_2 are in 12 (*a*) and 16 Rb or Cs are in 16 (*c*). In each case the parameter *x* is 2/37. Rb-O_2 distances are 3.54 and 2.95 A. Cs-O_2 distances are 3.74 and 3.12 A.
W. F. Bradley

The crystal structure and magnetic properties of metallic holmium. Heinrich Bommer. *Z. anorg. allgem. Chem.* 242, 277-80(1939); cf. *C. A.* 33, 5718[9], 6102[8].—Metallic Ho, prepd. by reducing $HoCl_3$ with K, crystallizes in the hexagonal close-packed arrangement with $a = 3.557 \pm 0.003$ A., $c = 5.620 \pm 0.005$ A., $c/a = 1.580$. The at. radius, with coördination no. 12, is 1.759 A.; the at. vol. is 18.65 cc. and the x-ray d. = 8.764. The magn. susceptibility corresponds to 10.6 Bohr magnetons.
L. L. Quill

Adsorption, flocculation and flotation of oxide minerals. Gust. G. Bring. *Jernkontorets Ann.* 123, 229-65(1939).—The quantity of fatty acid salts adsorbed from soln. was measured for apatite, hematite and quartz. Apatite adsorbed most and quartz least. Large particles adsorbed more per unit surface than small ones. Flotation was more effective with hematite and apatite than with quartz, but there was no good correlation between adsorption and ease of flotation. Reagent losse in flotation were smaller than calcd. on the basis of adsorption. Flocculation improves flotation initially, but with strong flocculation the flotation became less effective.
H. C. Duus

Active substances. XXXVIII. Further investigation of active substances by the method of Otto Hahns. Robert Fricke and Hans J. Bückmann. *Ber.* 72B, 1199-1206 (1939); cf. *C. A.* 33, 6690[8].—The increase in e. m. f. of active substances by H_2O adsorption was investigated. Expts. on the hydration of active MgO showed that the H_2O is first adsorbed and then chemically combined. The e. m. f. increases with the adsorption of H_2O and then decreases. The decrease in e. m. f. for finely divided γ-Fe_2O_3 was investigated up to very high pressures. With strongly pressed γ-Fe_2O_3 a decrease in e. m. f. instead of an increase (owing to H_2O adsorption in unpressed material) was obtained, because the adsorbed H_2O only replaces the air in the small capillaries and causes no change in the secondary structure. The strongly pressed samples take up much less H_2O and hold it more firmly than the unpressed samples. CuO cooled from a higher ignition temp. to room temp. showed, in contrast to slowly cooled CuO, a smaller e. m. f. During the adsorption of H_2O the e. m. f. is high, owing to stronger adsorption.
W. G. P.

Chemical specificity of various activated forms of the same crystalline structure. II. γ-Al_2O_3. Robert Fricke and Heinz Deifel. *Ber.* 72B, 1568-72(1939); cf. preceding abstr.—γ-Al_2O_3 with varying primary particle size adsorbs K^+ and PO_4^{---} from the equiv. K_2HPO_4 soln. in varying molar ratios. With increasing particle size the amt. of K^+ adsorbed increases in proportion to the amt. of H_3PO_4. The acid character of the adsorbent accordingly increases in the ratio of the alkalinity. **III. ZnO and α-Fe_2O_3.** Robert Fricke and Hermann Keefer. *Ibid.* 1573-6.—By measuring the increase of adsorption of K^+ and AcOH from K acetate soln. it was found that the ratio of the strength of the acid to that of the basic properties increases with activated ZnO with decreasing heat content. The trend of these ratios was reversed with activated α-Fe_2O_3. With ZnO increasing heat content was reduced chiefly by irregular lattice disturbances. The particle size (surface area) is important with α-Fe_2O_3.
W. George Parks

Correspondence between changes of state in two and three dimensions. D. G. Dervichian. *J. phys. radium* 10, 333-49(1939).—The states of uninol. films are shown to reproduce in detail the ordinary phys. states of matter. Solid, liquid, liquid-cryst. and gaseous states are considered. In the solid state of the film the correspondence with different cryst. forms is illustrated by the 2 states of films of the glycerides of myristic, palmitic and stearic acids. A theory of liquid films is developed. The existence of a transition state in films analogous to the liquid-cryst. state of matter in bulk is discussed. Crit. temps. for liquefaction and cryst. are introduced for superficial films. A summary of possible cases is given.
H. C. T.

Stability of bitumen emulsions. A. S. Korzhuev and V. V. Gridchina. *Zavodskaya Lab.* 8, 739-42(1939).—The stability of bitumens emulsified mechanically with various amts. of liquid soap, NaOH and water was tested in a centrifuge and the results are given in curves. For the same amt. of NaOH (0.2-0.33%) the emulsions contg. 2-2.4% soap were uniform, finely dispersed and stable, [illegible] is uniform [illegible] amt. of [illegible] content of the emulsifier. The emulsion contg. 2-2.4% soap had

the max. amt. of bound water and was more uniform and highly dispersed. The quality of the emulsions depended also on the pH. The more uniform and stable emulsions were obtained at a pH of 11–12. Conclusion: The quantity of water in the emulsified bitumen can be used to est. the stability of emulsions. B. Z. Kamich

Brownian molecular motion. Eugen Kappler. *Naturwissenschaften* **27**, 649–58, 666–70(1939).—A review of mol. motion, Brownian motion with and without external forces and its math. development. The influence of Brownian motion on measurements and its observation without microscope are discussed in some detail.

B. J. C. van der Hoeven

Determination of crystalline size from the broadening of electron interference. Th. Schoon and R. Haul. *Z. physik. Chem.* **B44**, 109–26(1939).—The size of ultramicroscopic crystals can be detd. from the broadening of electron-interference patterns similar to that with x-rays (cf. *C. A.* **24**, 2043). A standard prepn., which is free from increase of particle size, is needed. The method is most useful for sizes between 70 and 10 A. and for the smaller sizes is more certain than the x-ray method. Crystals of γ-Fe_2O_3, prepd. by the decompn. of $Fe(CO)_5$ in the presence of O at various temps., were studied and the smallest particle was about 17 A. This is the smallest stable nucleus of the oxide. The method is not precise enough to det. lattice consts. The theory of Lennard-Jones (cf. *C. A.* **25**, 1719) concerning the dependence of lattice spacing on crystal size could not be tested.

G. M. Murphy

Determination of the specific surface of fibrous materials. E. J. Wiggins, W. B. Campbell and O. Maass. *Can. J. Research* **17, B**, 318–24(1939).—The Kozeny equation (*Sitzber. Akad. Wiss. Wien, Math.-naturw. Klasse*, Abt. IIa, **136**, 271–306(1939)) relating specific surface and permeability of a bed of unconsolidated particles is applicable to fibrous materials such as glass, wool and celanese. The diam. of the constituent fiber may be as small as 0.0006 cm., while the ratio of length to diam. may be indefinitely large. Uniformity of size or of packing is not essential. H_2O and C_6H_6 were the liquids used.

J. W. Shipley

The effect of ultrasonic waves on colloidal phenomena. VI. The effect of ultrasonic waves on the rotation of high-molecular colloidal substances. 2. Experiments with tannin solutions. Naoyasu Sata. *Kolloid-Z.* **88**, 182–4(1939); cf. *C. A.* **33**, 7172⁴.—After exposure of 1, 5 and 15% solns. of tannin in H_2O and EtOH to ultrasonic waves no reduction in their rotation could be observed. However, the aq. solns. became darker and more turbid after exposure. Expts. in vacuum showed that this is due to the O from the air. The hydration layer of tannin is assumed to be thinner than that of gelatin, but firmer; hence the former is not affected by ultrasonic waves.

J. A. Szilard

Capillary systems. XXII. (4) The preparation and characterization of electropositive membranes. Erich Manegold and Karl Kalauch. *Kolloid-Z.* **88**, 257–73(1939); cf. *C. A.* **33**, 7173⁶. Positively charged membranes were prepd. whose dialysis potential in the cell 0.1 *N* KCl—membrane—0.01 *N* KCl amounted to −50 to −50 mv., so that the membranes could be regarded as nearly 100% permeable to anions. From electroosmotic and electrodialytic measurements it appears that the constancy of charge on these cellulose ester membranes, charged by sorption and impregnation, is not great enough to effect displacement of neutrality in solns. flowing through them. The dependence of the dialysis potential on the concn. of electrolytes and the fixed charges on the membrane substance was calcd. anew according to the equation of Meyer and Sievers (cf. *C. A.* **31**, 925¹) for the following values of the mobility quotients: ratio of concn. $c_r = 2$ c_a, u/v = 1000, 100, 10, 0.1, 0.01, 0.001; ratio of concn. $c_r = 10$ c_a, u/v = 1000, 100, 10, 7, 3, 1.67, 1.0, 0.60, 0.33, 0.14, 0.10, 0.01, 0.001, 0.0001. A new procedure is described for measuring the electroosmotic permeability of the membranes to water. If the dil. soln. in the upper cell is replaced with distd. water or with a highly dil. soln. of KCl the potential then measured depends upon whether or not the dil. soln. flows through; if the flow is interrupted the measured potential is always some millivolts neg. It is assumed that a diffusion potential is involved which is superimposed on the dialysis potential. When the customary KCl concn. is used, this effect does not appear. It must be taken into account, however, if the concn. of the fixed charges on the membrane substance is to be calcd. from the dependence of the dialysis potential on the concn. of salt. F. L. B.

The necessity of admitting chemical affinity between solvent and solute. O. Scarpa. *Atti accad. Lincei, Classe sci. fis. mat. nat.* **29**, 247–53(1939).—Math.

A. W. Contieri

Determination of molecular weights of high-boiling oil fractions. K. S. Ramalya and K. A. Shchegrova. *Zavodskaya Lab.* **8**, 404–8(1939).—Expts. by the authors and other workers on the detn. of the av. mol. wt. of pure hydrocarbons and high-boiling oil fractions by the cryoscopic method are reviewed critically. In detg. the temp. depression (Δt) it is necessary to introduce corrections by extrapolating the cooling curve after the start of crystn. The cryoscopic const. of the solvent (C_6H_6) should be detd. experimentally in each case and reduced to zero concn. to make it independent of the nature of the dissolved compd. In view of the effect of the concn. of the dissolved compd. upon the apparent mol. wt. the former should be extrapolated to zero concn. The mol. wts. of α-methylnaphthalene and naphthalene as detd. by this modified method differ from the theoretically calcd. values by less than 0.05%. Tabulated and graphical data of mol.-wt. detns. of solar and lubricating oils are given. Curves are given showing the cooling rates of C_6H_6 and C_6H_6 soln. of naphthalene, cryoscopic consts. of C_6H_6 in various hydrocarbons, and the effect of the concns. of naphthalene and α-methylnaphthalene upon their mol. wts.

B. Z. Kamich

The properties of dipicrylaminates. Jacob Kielland. *J. Am. Chem. Soc.* **61**, 2285–9(1939). A short color analysis of dipicrylaminates (I) was made. The molar vols., ds. of aq. solns., f.-p. depressions, equiv. conds. and heats of soln. of the Na salts were also detd. Strong assocn. effects due to van der Waals forces exist between the anions of I in dil. aq. solns. An interesting case of partial miscibility was noted in mixts. of I with aq. $CaCl_2$ solns.

H. W. Leahy

Electrolytic conductivity and hydrogen bridge formation. P. Vulff. *Naturwissenschaften* **27**, 661(1939).—Recently it was found (*Z. physik. Chem.*, in press) that in the system C_6H_6–EtOH cond. depends upon presence of traces of water. If it is assumed that all this water is dissocd., the protons probably assoc. with OH of the alc. Furthermore it is assumed that polar assocd. complexes with many OH groups are formed. Considering that the proton belonging to one of these OH groups can readily transfer its attachment to a neighboring OH group, it is easy to see how the polar assocn. phenomenon gives rise to cond.

B. J. C. van der Hoeven

The reduction-oxidation potential of earth. Yrjö Kauko and Maija Bonsdorff. *Suomen Kemistilehti* **12B**, 23–4(1939)(in German).—The system Pt|earth|glass electrode|0.09 *N* KCl + 0.01 *N* HCl|quinhydrone|Pt was used for the detn. of the reduction-oxidation potential of earth. The potentials under N_2 and under air for 5 samples of earth with pH values of 5.10, 4.85, 3.50, 3.29 and 5.01 were 518 and 632, 712, 729 and 725, 735 and 742, 745 and 740, and 535 and 550 mv., resp., calcd. against H_2 at 1 atm. pressure.

S. A. Karjala

Equilibrium reactions having high constants. N. A. Tatanac and M. S. Voshchinskaya. *Zavodskaya Lab.* **8**, 788–95(1939).—The reactions $AgBrO_3 \rightleftarrows AgIO_3$, $2AgBrO_3 \rightleftarrows Ag_2CrO_4$ and $Ag_2CrO_4 \rightleftarrows 2AgCl$ proceed to the right, 100% in 10 min. at 22°. For the third reaction the formation of AgCl goes to 100% in the presence of any excess CrO_4^{--}. The reaction $Ag_3Fe(CN)_6 \rightleftarrows 3AgCl$ goes 92.5% to the right and $L_p = 9.79 \times 10^{-26}$ for $Ag_3Fe(CN)_6$. The reaction $Ag_4Fe(CN)_6 \rightleftarrows 4AgBr$ could be

studied from the right to the left only and it proceeded to 2.88% and $L_p = 1.13 \times 10^{-42}$ for $Ag_4Fe(CN)_6$.
B. Z. Kamich

The gas-solid reaction as a function of its factors. E. Wicke. *Z. Ver. deut. Ing., Beiheft Verfahrenstech.* **1939**, 85–95.—Equations for isothermal reactions between gases and solids which are based on a univariable equil. are derived and related by means of pertinent factors. Graphic presentations are discussed. Equations are presented for the case of (1) const. concn. of the reacting gas in the free gas space, (2) const. reaction space and (3) gas stream through a long reaction path. Further subdivision into space reaction and surface reaction is used. 37 references. Karl Kammermeyer

Kinetics of the iodination of acetophenone in sulfuric and perchloric acid solutions. Lois Zucker and Louis P. Hammett. *J. Am. Chem. Soc.* **61**, 2791–8(1939).—The iodination of acetophenone was studied in 2 to 30% aq. $HClO_4$ solns. and in 0.5 to 66% aq. H_2SO_4 solns. The rate is detd. by the rate of enolization of acetophenone in the more dil. solns. and by the rate of the reaction of the enol with I in 51% and more concd. H_2SO_4 solns.; at intermediate acidities these 2 rates are of comparable magnitudes. A. B. Garrett

Trans-cis mutation of some cobaltic complexes. Jules Brüll. *Compt. rend.* **209**, 630–2(1939); cf. *C. A.* **31**, 2118².—The velocity, k, of the transformation *trans*-$[Co\ en_2\ X] \rightarrow$ *cis*-$[Co\ en_2\ X]$ in 0.01 *M* soln. in presence of 0.15 *M* KBr, KCl or KBr, HCl was observed. For X = Cl_2, Br_2 or (Cl, H_2O) $k \times 10^4$ = 1.09, 7.82 and 6.66, resp., the reaction is unimol. With X = $(NH_3)_2$, (NH_3, H_2O) or (NH_3, Cl) no such transformation occurs, but with X = $(H_2O)_2$ transformation is very rapid, being specially sensitive to the presence of acid. C. A. S.

Excitation of chain polymerizations by free radicals. II. Evolution of free radicals by decomposition of an azo compound. G. V. Schulz. *Naturwissenschaften* **27**, 659–60 (1939); cf. *C. A.* **33**, 8000⁶.—The polymerization of styrene by triphenylmethylazobenzene was studied. The azo compd. decomposes at 50–60° yielding free Ph_3C + Ph + N_2, 2 mols. of free radicals per mol.; it is finished in 3 hrs. at 70°. After this period no more polymerization takes place, the thermal polymerization being 10^5 times slower than the one excited by free radicals. Up to concns. of 3×10^{-5} moles azo compd. per mole styrene there is formed 1 mole polystyrene per mole azo compd. This yield drops for higher concns. (up to 66.7×10^{-5} mole per mole) to 31.5% owing to a side reaction consuming free radicals. The primary reaction at low concn. is purely a first-order one at 50 and at 60°, following $k = -(1/t) \log (1 - (x_t/x_\infty))$ with $\log k = 10^{12.2} e^{-23,500/RT}$, the times required for half termination of the reaction (half-period) being 54 and 21 mins. at the above temps. At higher concns. the soln. has a weak yellow-green color owing to a by-product formed from the free radicals as shown from calcd. and measured reaction consts. The degree of polymerization of the styrene as a function of the azo compd. concn. shows that fracture of the reaction chain takes place by 2 mechanisms: (1) 2 growing chains unite, and (2) a free radical joins the chain. The first mechanism requires that (gross reaction rate) × (degree of polymerization) = const.; actually it decreases somewhat with increasing azo compd. concn. With increasing azo compd. concn. the second type fracture predominates more and more, the av. ratio of the 2 types of fracture is 1 to 2–3. The azo compd. as such does not cause chain fracture.
B. J. C. van der Hoeven

Effect of ionic concentration on the degree of hemolysis in neutral salt solution. Hideo Takatuki. *J. Cantonese Med. Assoc.* **29**, 709–93(French abstr., 47)(1939).—The degree of hemolysis of both nucleated and nonnucleated erythrocytes by NaCl, $SrCl_2$, Na_2SO_4 and $MgSO_4$ solns. is proportional not to mol. equiv. or theoretic ionic concns., but to actual ionic concns. of the solns. calcd. from elec. cond., f. p. and Debye-Hückel effect of strong electrolytes.
S. Tashiro

Kinetics of oxidation of iodide by chlorate ion in the presence of catalysts. II. Ruthenium chloride as catalyst. Karl Weber and Ramiza Valić. *Ber.* **72B**, 1485–95 (1939); cf. *C. A.* **33**, 4498⁴.—The reaction velocity was detd. in the presence of varying concns. of HCl and $RuCl_3$. The dependence of the velocity const. on the concn. (0.005 – 0.25 *M*) of $RuCl_3$, $MnCl_2$, Na_2SO_4 and $NiSO_4$ was investigated. The neg. catalysts Na_2SO_4 and $NiSO_4$ were studied over a wide concn. range. The value of the velocity const. (0.05 *M* HCl) is 0.1280 at 25° and 0.3355 at 40°. The temp. coeff. for 10° is 1.90 and the activation energy 11,900 cal. W. George Parks

The physical chemistry of interfacial reactions. E. Wicke. *Z. Ver. deut. Ing., Beiheft Verfahrenstech.* **1939**, 127–30.—A discussion covering the following subjects: adsorption, kinetic processes at the interface, importance of the interface in reactions of solids, catalysis and energy-exchange at the interface. 17 references. K. K.

Catalytic hydrogenation of ethylene on copper-nickel alloys. G. Rienäcker and E. A. Bommer. *Z. anorg. allgem. Chem.* **242**, 302–12(1939); cf. *C. A.* **32**, 4416⁹.—The reaction velocity for the hydrogenation of C_2H_4 on Cu-Ni alloys shows a marked increase when the Ni content reaches 19.2–19.8 at. %. This compn. approximates that at which the alloy changes from red to white. The increase in catalytic activity is greater than is to be expected from the activation energies of Ni and Cu. Possibly it is caused by an increase in the no. of active areas on the surface of the catalyst. J. H. Reedy

Vapor-phase catalytic oxidation of organic compounds. Production of tolualdehyde and phthalic anhydride from xylene. W. Geo. Parks and Chauncey E. Allard. *Ind. Eng. Chem.* **31**, 1162–7(1939); cf. *C. A.* **30**, 2836⁸.—Compds. of Mo, V, Fe, Cr, Sn, Zr, Mg, K, W, Ti and Al were used separately and in various combinations as catalysts in the direct oxidation of xylene either in granular form or on a support of porous Al, activated alumina, asbestos fiber, silica gel, pumice or Alfrax. The effect of temp., time of contact and air/xylene ratio upon the type and amt. of product was studied. Results on 15 catalysts that showed an appreciable effect are reported. With a tin vanadate catalyst at 320°, a time of contact of 0.002 min.; and an air/xylene ratio of 13.4, a yield of 8% phthalic anhydride was obtained. With a V_2O_5 catalyst supported on Alfrax at 530° and an air/xylene ratio of 34, 18% phthalic anhydride was obtained. This catalyst gave yields varying from 45 to 85% phthalic anhydride on the basis of the amt. of xylene oxidized per pass. W. G. P.

Some properties of the dioxane–ethanol system. Robert W. Hopkins, Earle S. Yerger and Cecil C. Lynch. *J. Am. Chem. Soc.* **61**, 2460–1(1939).—The d., n_D and η data for the dioxane ethanol system are presented. The η curve passes through a min. at 50% dioxane concn. The b. ps. and the b. p.-compn. diagram were also detd. A min. b. p. of 78.13° was observed at 9.3% dioxane.
H. W. Leavy

Equilibria in the systems ethanol–water, ethanol–cellosolve and cellosolve–water. E. M. Baker, R. O. H. Hubbard, J. M. Huguet and S. S. Michalowski. *Ind. Eng. Chem.* **31**, 1260–2(1939).—By means of a special still, binary combinations of water, ethanol and cellosolve were distd. at 730 ± 1 mm.. A special head was used to prevent the return to the boiler of any vapors condensed in the upper portion of the column. The vol. of distillate withdrawn for analysis was small in comparison with the amt. of liquid in the still. The compn. of the distillate was detd. by refractometer and pycnometer measurements, and curves for the 3 systems were constructed. The system cellosolve–water has a const. boiling mixt. contg. 92.1 mole % of water, instead of 83.3 mole % as previously reported. J. H. Reedy

Equilibria between liquid and vapor in the system ethanol–cellosolve–water. E. M. Baker, R. E. Chaddock, R. A. Lindsay and R. C. Werner. *Ind. Eng. Chem.* **31**, 1263–6(1939).—By use of the app. referred to in the preceding abstr., *n*-compn. and d.-compn. curves were constructed for the systems ethanol–water, cellosolve–water and cellosolve–ethanol. A tertiary diagram for the whole system was constructed by keeping the mole % of cellosolve const. and varying the relative proportions of

ethanol and water. Corrections were made to adjust the compn. of liquid and vapor before the data were plotted. The accuracy of the data was estd. at 0.5 mole %. There was no evidence of a ternary const.-boiling mixt.
J. H. Reedy

The system NaCl–$NaClO_3$–H_2O. Arrigo Linari. *Ann. chim. applicata* **29**, 189–95(1939).—The equil. diagrams of the system at pressures down to 288 mm. Hg are detd. At 435 mm., b.-p. of the mix = 98.0° and ratio $NaClO_3$/NaCl = 3.841; at 400 mm., b. p. is 93.8°, $NaClO_3$/NaCl = 3.73; 366 mm., b. p. 92.5, ratio 3.89, 330 mm., b. p. 88.1°, ratio 3.80; at 28° mm., b. p. 84.9°, and ratio 3.91.
A. W. Contieri

Phase equilibrium relations in the system, Na_2SiO_3–Li_2SiO_3 SiO_2. F. C. Kracek. *J. Am. Chem. Soc.* **61**, 2863–77(1939); cf. *C. A.* **33**, 8783⁵.—The phase equil. relations, detd. by the method of quenching supplemented by thermal analysis, are described. The inversion temp. of quartz and tridymite of 870 ± 10° was confirmed. The *n*s of glasses of various compns. in the system were measured. Solid-soln. relations of Na and Li compds. in general are discussed and minor revisions are presented for the phase relations in the systems, Na_2SiO_3–SiO_2 and Li_2SiO_3–SiO_2.

The problem of standards and mathematical signs in chemical thermodynamics. Erich Lange. *Kolloid-Z.* **88**, 89–96(1939); cf. *C. A.* **31**, 3776².—A simple reversible thermodynamic transition of energy between a substance (system) and an external energy (receiver) is completely characterized by the changes of their energies. This transition of energy can be simplified and sufficiently distinguished only by the standard. The decision between 2 magnitudes that have different initial signs depends on which standard is selected. The problem of transition from the standardless to the standard thermodynamics is discussed. The characteristic of a transition of energy in the sense of a "principle of the pos. abs. no." also in the sense of a "principle of the uniform standard" is considered. General observations are made on the real and historical state and to the desired solution of the problem. A system is suggested. 37 references.
W. G. P.

Calorimetric study of the system SiO_2–CaO–H_2O. Vittorio Cirilli. *Ricerca sci.* **10**, 459–61(1939); cf. *C. A.* **32**, 9428².—Plots of the no. of cal. per g. of CaO (370–520) against the ratio CaO/SiO_2, both dry and hydrated show that the heat of hydration increases with diminution of Ca. Two discontinuities correspond to CaO/SiO_2 = 1 and 1.5, resp. The former corresponds to the compd. SiO_2.CaO.H_2O, the latter, less distinct, to 3CaO.$2SiO_2$.–xH_2O. A plot of CaO g./l. (0.2 to 1.5) shows both discontinuities more clearly, and a study of the rate of dehydration gives like results.
W. F. Bruce

Hydrated calcium aluminates. Vittorio Cirilli. *Ricerca sci.* **10**, 556–62(1939).—The heats of soln. (cal./mol.) and heats of hydration for a series of hydrates are reported as follows: $3CaO.Al_2O_3$, 198.6, —; $12H_2O$, 126.1, 72.5; $9.4H_2O$, 129.8, 68.3; $7.3H_2O$, 34.7, 63.9; $6H_2O$, 140.2, 58.3; $2.7H_2O$, 165.5, 33.1; $1.5H_2O$, 173.1, 25.5; 2CaO.–Al_2O_3, 141.4, —; $8.8H_2O$, 97.6, 43.8; $7.24H_2O$, 103.1, 38.3; $5H_2O$, 108.9, 32.5; $3.8H_2O$, 115.2, 26.2; $1H_2O$, 1?4.0, 7 4; $0.63H_2O$, 137.0, 4.4; $4CaO.Al_2O_3$, 246.28, —; $12.8H_2O$, 154.0, 92.28; $11H_2O$, 158.9, 87.28; 9.46–H_2O, 162.1, 84.18; $8H_2O$, 165.8, 80.48; $4.9H_2O$, 191.6, 54 98; $2.5H_2O$, 2?0.5, 35.78. The intermediate hydrates in the first series are mixts. of dodecahydrate, hexahydrate and anhyd. material, a conclusion supported by Debye spectra. In the second series likewise, $5H_2O$ is held as H_2O of constitution, with various mixts.; but in the higher hydrates some H_2O is held as in zeolites. In the last series, $1H_2O$ is held as H_2O of constitution, the remainder as zeolitic H_2O. The Debye spectra of all these series are very similar.
W. F. Bruce

A new determination of the heat of formation of the oxides of manganese. H. Siemonsen. *Z. Elektrochem.* **45**, 627–43(1939).—The following heats of reaction were measured calorimetrically at 25°; ΔH is expressed in kg.-cal./mol.: $3Mn + 2O_2 = Mn_3O_4$, −336.5 ± 0.2; $3MnO + {}^1/_2O_2 = Mn_3O_4$, −57.0 ± 0.5; $3Mn_2O_3 = 2Mn_3O_4 + {}^1/_2O_2$, −24.8; $3MnO_2 = Mn_3O_4 + O_2$, −39.2. From these values the following heats of formation were deduced at 25°; Mn_3O_4, −336.5 ± 0.2; MnO, −93.1 ± 0.3 (combined with data of Roth[b]); Mn_2O_3, −232.7 ± 0.3; MnO_2, −125.4 ± 1.0 kg.-cal./mol.

3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

A. B. F. DUNCAN

The application of thermodynamic considerations to the normal state of the atomic nucleus. Satosi Watanabe. *Z. Physik* **113**, 482–513(1939).—The wave function of the normal state of a true nuclear atom deviates from that of the Hartree approximation in the sense that our knowledge of the state of a nuclear constituent particle is less than in the Hartree model. This makes it possible to characterize the wave function of a constituent particle through the distribution function and the entropy. The improvement in the Thomas-Fermi model of a heavy nucleus brought about by Euler by means of the perturbation calcn. deviates from the formalism of the Hartree model in so far as it approximates to a temp. distribution of impulse. In this investigation the surface effects and the Coulomb force are neglected.

The atomic constants *e*, *m* and *h*. F. Kirchner. *Ergeb. exakt. Naturw.* **18**, 26–77(1939).—A review, concluding with the present best values $e = 4.803 \pm 0.004 \times 10^{-10}$; $e/m = 1.759 \pm 0.0015 \times 10^7$; $m = 9.108 \times 10^{-28}$; *h* is either 6.626 (calcd. from the foregoing by the Ryd-

G-10221

berg formula) or 6.614 × 10^{-27} (from h/e as detd. by short wave limits in x-ray spectra). The discrepancy in the 2 values of h is left unexplained. 104 references.
C. D. West

Notes upon the electron pressure in the theory of plasma vibrations. R. Seeliger and M. Steenbeck. *Z. Physik* **113**, 526–30(1939).—In the elementary theory of plasma vibration given by Langmuir, the electron pressure is not taken into account. It is shown that the electron pressure plays no quantit. part and that the Langmuir frequency formula is correct from a practical point of view. S. Tolansky

The plasma state of gases. R. Rompe and M. Steenbeck. *Ergeb. exakt. Naturw.* **18**, 257–376(1939).—The first complete review of the subject of gases in the highly ionized state, named "plasma" by Langmuir. 579 references. C. D. West

Excess temperature in the glow discharge. Heinz Fischer and E. Golz. *Z. Physik* **113**, 360–6(1939).—The mean excess temp. in the glow discharge is studied with plane and hollow cathodes. Observations are made with H_2, He, Ne, A and air. Al is used as the cathode material in all cases. The pressure range studied is 0.1 to 8 mm. Cathode-fall energies up to 10 w./sq. cm. are measured. S. Tolansky

Luminescence of mercury vapor along an α-ray pencil, and transfer of nitrogen excitation to mercury. A. Luyckx. *Proc. Roy. Soc.* (London) **A172**, 492–501 (1939).—The green luminescence caused by α-rays in H_2 contg. Hg vapor was found to be due to the Hg triplet (5461, 4358, 4046 A.), a continuum with max. near 4850 A. and the resonance line 2537 A. Persistent phenomena were observed. No luminescence was found in the absence of N_2. The green luminescence was extinguished by air; H_2 had no quenching effect. H. C. Thomas

Total and partial power of emission of certain substances. II. A. Carrelli. *Atti accad. Lincei, Classe sci. fis. mat. nat.* **29**, 381–8(1939).—The emissivity of Pt, Ag, NaCl, LiCl, and KCl and also $CaSO_4$ and Na_2SO_4 were detd. in the temp. range 250–770°. The exponents were found to be 5.16 and 4.55 for Pt and Ag, resp., about 4 for all 3 chlorides, a value greater than 4 for the sulfates, while no definite values could be detd. for ZnO, MgO, CaO and CoO. A. W. Contieri

Energy distribution of secondary electrons at low temperature. Alexandre Bojinesco. *Compt. rend.* **209**, 512–13(1939).—The secondary electrons were obtained by bombarding an Al target with primary electrons of energy 300 e. v. They are captured by a sphere at potential v at the center of which the target is placed. The current thus collected at 90.5° and 293° abs. is plotted against v. Results show 3 groups of electrons: (1) primary electrons reflected at the target; (2) a group of energy 280–45 e. v. due to diffusion of primary electrons by atoms of the metal; and (3) a numerous group of energy 45–0 e. v., the true secondary electrons. The no. of secondary electrons of energy 45–0 is much smaller at the lower temp., while for those of energy 45–300 e. v. the curve for 293° is below that for 90.5°. This is possibly due to change in the cryst. structure of the metal at the lower temp. C. A. S.

An electrostatic high-tension lens of short focus. Manfred v. Ardenne. *Naturwissenschaften* **27** 614–15(1939).
F. J. C. van der Hoeven

The selenium photoelement. III. Properties in the high-frequency circuit. Fritz Goos. *Z. Physik* **113**, 334–49(1939).—A method is described enabling investigations to be made on the Se photoelement in high-frequency fields. The almost momentary photoeffect of the insulating layer with a spectral max. in the yellow-green does not come into action when high-frequency fields are used. The phenomena occur entirely in the base material. Investigations are made of time effect, spectral effect, light intensity and temp. effect. It is shown that there are certain relations between the observations and the properties of ZnS phosphors, from which it is concluded that a similar mechanism operates. The observations are explained as resistance-capacity changes in the semiconducting base material. S. Tolansky

The transformation of impulse voltages. With an appendix upon observations upon the scatter of electrons in the cloud chamber. Egon Heuse. *Z. Physik* **113**, 514–25(1939).—Investigations are made to see how far a transformation of impulse voltage in an air transformer can be used for the production of fast electrons. A voltage impulse is sent through the primary of an air transformer and the voltage produced in the secondary is employed for the acceleration of the electrons. The electron energies are measured with a cloud chamber. As high primary voltage impulses can easily be obtained, the method can possibly be adapted for use. Unfortunately after numerous expts., only a transformation ratio of 1.6 can be obtained. The method is therefore not very practical. In an appendix the paths of the electrons are studied.
S. Tolansky

Light excitation through homogeneous canal rays of low velocity. F. Engelmann. *Z. Physik* **113**, 462–81(1939).—A canal ray app. is described, enabling the light excitation to be studied for the collision of 2 corpuscular bodies. Measurements can be made in the low-voltage region, (1 to 10 kv.). The particles are produced in an arc discharge. By means of multiple acceleration of the ions of the arc, very homogeneous beams of canal rays are created. Both the homogeneity and the ion yield are better than with the usual Wien type of canal ray tube. Collisions of H atoms and ions with He are studied. In collisions of neutral H particles, the Balmer lines are found in the whole excitation voltage region, but the He excitation sets in only at 2000 v. In the case of collisions with H ions, very strong He excitation is observed. In order to distinguish between the effects of the different ions, expts. are made with high arc pressure (H_3^+) and in addn. magnetic analysis is employed. No precise expt. results are found, but it is very probable that the strong He excitation is produced by protons. This fact is in agreement both with other observations and with theoretical considerations. Excitation studies are made upon both light and heavy hydrogen. In a certain region the heavy hydrogen is more effective. In A collisions it is found that both excitations are the same. The observations made here are in agreement with the hypothesis of v. Dopel (cf. *C. A.* **30**, 6637[2]) upon the work involved in corpuscular collisions.
S. Tolansky

The scattering of α-particles in helium. S. Devons. *Proc. Roy. Soc.* (London) **A172**, 559–67(1939); cf. *C. A.* **33**, 8104[7].—The scattering of α-particles in He has been investigated for scattering angles of 27° and 38.5° for energies up to 8.5 m. e. v. The results are consistent with a broad level of Be^8 (which is assumed to possess a mass of 2 α-particles) with spin of 2 quantum units and with an energy of about 3.3 m. e. v. in excess of that of the ground state H. C. Thomas

Shower production by penetrating cosmic rays. A. C. B. Lovell. *Proc. Roy. Soc.* (London) **A172**, 568–82(1939).—A counter-controlled cloud chamber was used to obtain 5000 photographs contg. 463 electronic showers of not fewer than 5 particles. The effects can be accounted for as cascade showers produced by an electron which has been knocked-on by a direct collision with a meson.
H. C. Thomas

Absorption of penetrating cosmic ray particles in gold. J. G. Wilson. *Proc. Roy. Soc.* (London) **A172**, 517–29 (1939).—Absorption measurements of the penetrating component of cosmic radiation in 2 cm. Au indicate that absorption at energies $\sim$700 m. e. v. is due entirely to ionization. A very low energy track gave an estimate of the meson mass (170 ± 20) M_0. At energies >700 m. e. v. a few particles, probably protons, were observed which appeared to undergo greater absorption. It is suggested that a strong absorption of protons with the production of mesons takes place in 2 cm. Au. H. C. Thomas

Variations in great showers of cosmic rays with barometric pressure, altitude and time. Pierre Auger, Robley and Pluvinage, *Compt. rend.* **209**, 526–8(1939); cf. *C. A.* **33**, 3680[5].—From expts. at (I) Paris, and (II) Pic-du-midi (atm. pressure, resp., 10.3 and 7.3 m. H_2O) it is shown that the no. of great showers, N, of cosmic

rays recorded at II is approx. 3 times that at I (180 and 60), while the density of a shower (no. of trajectories/sq. m./hr.) at II is twice that at I (40 and 20); the nos. of coincidences per hr. at the 2 places with 2 counters (n_2) are 24.1 and 7.5/hr., and with 3 counters (n_3) 8.9 and 2.5, resp. Variations in n_2 at the same place follow closely those in barometric pressure, but appear to be quite independent of temp. There is no measurable diurnal variation in N. It may therefore be concluded that the directions of propagation of cosmic rays throughout the energy spectrum are distributed isotropically in space far from any celestial body. C. A. Silberrad

Long-lived radioactive isotopes of cobalt. Giovanna Barresi and Bernardo N. Gaccia puoti. *Ricerca sci.* **10**, 464-6 (1939).- Bombardment of Co or Fe with neutrons or deuterons yielded Co with half life of from 100 days to 5 or 10 yrs. (cf. Livingood, Fairbrother and Seaborg, *C. A.* **31**, 6552[2]; Risser, *C. A.* **32**, 425; L. and S., *C. A.* **32**, 5299[9]). Active Co prepns. from various sources were examd. to det. the half-life periods. Curves covering 450 days are shown for 6 samples. Three distinct types of Co were found: bombardment of Co with neutrons gave a prepn. with a half life of 4.7 yrs., a half life of 264 days and one of 58 days were obtained from Fe + deuterons. In various combinations these 3 account for all the observed results. A sample 17 months old in which the shortest-life portion was practically exhausted allowed exact detn. of the intermediate type. W. F. Bruce

The electron and positron spectrum of radioactive arsenic. W. Schaeffer and P. Harteck. *Z. Physik* **113**, 287-91 (1939).- Previous investigations upon the radioactive $_{33}As^{76}$ atom are extended and certain of the questions relating to the ordering of the thermal scheme are explained S. Tolansky

Relation between the half-life period and atomic weight of β-radioactive isotopes. Mario Ageno. *Ricerca sci.* **10**, 466-8 (1939).- A plot of at. wt. against $1/\log T$ where T is the half-life period often gives for the various isotopes of a given element a linear relation. Graphs for V, Nd and Tl are given. W. F. Bruce

Measurement of β-β coincidences. F. Norling. *Naturwissenschaften* **27**, 593 (1939).—An improved method for observation of β-β coincidences was found by setting up a vertical screen between 2 horizontal counter tubes and fastening the β prepn. above the edge of the screen. Scattering from one tube to the other is thus avoided. Thin-walled counter tubes are used under atm. pressure. A test of this method on Ra E and Au^{196} showed the 10% β emission of the gold in agreement with former work of Richardson (*C. A.* **33**, 6114[6]). B. J. C. v. d. H.

Cleavage of uranium. Bruno Ferretti. *Ricerca sci.* **10**, 471-4 (1939); cf. *C. A.* **33**, 9123[7].- Math. Calcn. of the probability that a given energy of excitation distributed over the 5 fundamental frequencies can call forth energy sufficient to produce rupture of the atom. W. F. B.

Separation of isotopes. W. Walcher. *Ergeb. exakt. Naturw.* **18**, 155-228 (1939).- The following methods of sepg. isotopes are reviewed and compared: electrolysis, diffusion, fractional distn. chem. exchange reactions, diffusion with a thermal gradient, centrifuge, mass spectroscope and photochem. reactions. Methods of detg. isotopic ratios in mixts. are also treated. The 192 references are complete since 1932 C. D. West

Experiments on the separation of isotopes. E. H. Riesenfeld *Arkiv Kemi, Mineral. Geol.* **13A**, No. 16, 11 pp. (1939).—The Hertz diffusion method (cf. *C. A.* **20**, 6774) of sepg. isotopes is improved by using continuous flow in an open system instead of a closed system. The advantages are: the expt. can be stopped at any time, since equil. among the units is established very quickly; the sepn. factor is about double that of the closed app. with the same no. of units; yield of product is increased. With a three-unit system, the sepn. factor for N^{15} is 4.5 and the yield per min. is 0.5 cc. The corresponding figures with a closed system are 2.3 and 0.01. A more powerful pump than the one used here (a Boltwood pump) will further increase the sepn. G. M. Murphy

X-ray emission spectra and electronic structure of

1 **aluminum-copper and aluminum-nickel alloys.** J. Farineau. *J. phys. radium* **10**, 327-32 (1939); cf. *C. A.* **33**, 4510[5].- The distribution of intensity in the x-ray emission bands due to the exterior electrons of Al ($K\beta_{2'}$) and of Ni or of Cu ($L\alpha$) in the alloys Ni-Al and Cu-Al is investigated. The results are discussed in terms of the phys. characteristics of the alloys and the quantum theory of metals. The Brillouin zones seem to exist. H. C. Thomas

2 **X-ray examination of nucleic acids and their structure.** P. Mazza and G. Tappi. *Arch. sci. biol.* (Italy) **24**, 526-31 (1938).—Thymonucleic acid produces 3 rings (r = 11.6; 15.2; 19.4 mm.) in a diffused background. The mixt. of thymonucleic acid (in which β predominates) gives a spectrum typical of the amorphous phase, one ring corresponding to a period of 4.7 A. surrounded by a halo. Various samples of yeast nucleic acid always give amorphous results. Guanylic acid produces 3 rings:
3 r = 17.4 (weak); 19.8 (strong); 21.6 (less weak) with reticular distances corresponding to d = 3.8; 3.4; 3.1 A. The 2 adenylic acids give results which can only be given in a large table. P. F. Metildi

4 **Fine structure of x-ray absorption edges.** G. H. Klaasmer. *Nederland. Tijdschr. Natuurkunde* **6**, 225-33, 241-52 (1939).- Absorption of x-rays is reviewed and the influence of the crystal lattice on the fine structure. In the second part the fine structure of x-ray-absorption by mol. gases is considered and the theoretical results are compared with exp. data. B. J. C. van der Hoeven

5 **The number of lines in a series as a function of electron pressure.** Fred L. Mohler. *Astrophys. J.* **90**, 429-38 (1939).— The no. of lines that appear in a spectral series should be a function of the electron concn. alone for a discharge of high c. d. From previously reported data (*C. A.* **33**, 1207[8]) on the discharge through Cs is derived the relation N_e = 23.06 - 7.5 log n_m, where N_e is the electron concn., and n_m the effective total quantum no. at which the higher series members merge into a continuous spectrum. From this relation values of electron pressures in stars of classes A and B have been calcd. at the limits of the Balmer and Paschen series and at wave length 4340 A., the differences between the pressures depending on the differences in opacity of H at these wave lengths. C. C. Kiess

6 **Ionic depression of series limits in one-electron spectra.** D. R. Inglis and E. Teller. *Astrophys. J.* **90**, 439-48 (1939).—The broadening of the high series members of alk. spectra and their fusion into the continuum near the series limits as described by Mohler (preceding abstr.), are here shown to be the effect of ionization in the atm. surrounding the atoms. The ion density N is correlated with the quantum no. n of the line with which the series
7 terminates by the relation $Nn^{4.5} = 0.027a_0^{-3}$, where a_0 is the radius of the first Bohr orbit. The greater part of the line broadening is due to Stark effect of the pos. ions, to which is added the collisional effect of the electrons; but for temps. under $(10^5/n)$ °K. the broadening due to electronic impacts is small. C. C. Kiess

8 **The chemical nature of the coloration in Jupiter's cloud forms.** Rupert Wildt. *Monthly Notices Roy. Astron. Soc.* **99**, 616-20 (1938).—The atm. of Jupiter is composed largely of NH_3 as revealed by the spectroscope. The colored bands in this atm. are attributed to the formation of solns. of Na in NH_3, which for temps. above −112° are reddish brown in color. The yellowish tints are attributed to $NaNH_2$ into which the Na-NH_3 soln. decomps. slowly with liberation of H. Since the temp. of Saturn is much lower than that of Jupiter the absence of conspicuous belts in its atm. is understood. C. C. Kiess

New identifications of Fe III in the spectra of early B stars. P. Swings, B. Edlén and J. Grandjean. *Astrophys. J.* **90**, 378-86 (1939); cf. *C. A.* **33**, 1589[8].—The spectrum of Fe III was observed with a large quartz spectrograph from 2000 A. in the ultraviolet through the visible region. The analysis previously reported (*C. A.* **33**, 1589[8]) is extended; it leads to an ionization potential of 30.48 v. for Fe^{++}. Many of the new wave length;

agree with hitherto unidentified absorption lines in the spectra of class B stars. C. C. Kiess

Transition probabilities for He I. Leo Goldberg. *Astrophys. J.* **90**, 414-28(1939).—General expressions are derived for the line strengths in the $2s - np$ and $2p - nd$ series of He I. C. C. Kiess

The sodium *D* lines in the light of the night sky. G. Cario and U. Stille. *Z. Physik* **113**, 442-8(1939).— The previously reported observations and hypotheses relating to the yellow glowing layer between dawn and night are discussed. It is to be expected that measurements made upon the line widths of the emitted *D* radiation will throw some light upon the excitation processes and state of the sodium which occurs in the yellow layer. An app. for these measurements is described. S. Tolansky

The third spark spectrum of krypton, Kr IV. A. Balankeswara Rao and S. G. Krishnamurty. *Proc. Phys. Soc.* (London) **51**, 772-7(1939).— The spectrum of a condensed discharge of about 20,000 v. through capillary tubes contg. Kr was studied in the ultraviolet with quartz spectrographs. About 180 lines are ascribed to Kr IV and 60 of these, ranging in wave length from 2677.34 to 3934.29 A., are classified as combinations of 25 levels. Lacking data in the Schumann region to check the analysis of near-ultraviolet data, an attempt is made to identify the $5s\,^4P - 5p\,^4D$ and $5s\,^4P - 5p\,^4P$ multiplets by extrapolating the frequencies of corresponding lines from isoelectronic spectra As I, Se II, Br III. The intervals of the $5s\,^4P$ term are found to be 3100 and 3223 cm.$^{-1}$. W. F. Meggers

Hyperfine structure of spectral lines. H. C. Burger and P. H. van Cittert. *Nederland. Tijdschr. Natuurkunde* **6**, 109-81(1939).—A review. B. J. C. van der Hoeven

Structure of iridium lines. L. Sibaiya. *Phys. Rev.* **56**, 768-9(1939).—The isotopic constitution of Ir was first detd. by Venkatesachar and Sibaiya from a Lummer-Gehrcke interferometer study of the hyperfine structure of its arc line 3513.67 A (*C. A.* **30**, 19[6]). It was shown that Ir consists of 2 odd isotopes of mass nos. 191 and 193, the isotope 191 being half as abundant as 193. It was inferred also that their nuclear spin moments were $\frac{3}{2}(h/2\pi)$ and $\frac{9}{2}(h/2\pi)$, resp. Now the hyperfine structure of 5 Ir lines (3800.10, 3513.67, 2924.81, 2849.74, 2639.70 A.) has been investigated with Fabry-Perot etalon interferometers having aluminized quartz plates. From the level separations of the isotopes it is concluded that the ratio of the nuclear magnetic moments of Ir (191) and Ir (193) is −0.592. W. F. Meggers

The hyperfine structure of the iodine spectrum. Th. Schmidt. *Z. Physik* **113**, 439-41(1939).— The hyperfine structures of the $5p^5(^2D)6p\ ^3F_3$ and $5p^5(^2D)6s\ ^3D_2$ terms of the spark spectrum of I are detd. by observations made upon the hyperfine structures of the lines 6516 and 6127, use being made of a Fabry-Perot interferometer and a water-cooled hollow cathode discharge tube. According to Tolansky (*C. A.* **33**, 4517[5]) deviations from the quadratic law for the position of hyperfine structure levels occur here and are attributed to the existence of an octopole moment. He pointed out that the observations gave too high a value for the latter. According to the measurements reported here, the above terms are completely fitted by the quadratic formula characteristic only of a quadripole moment, no evidence being found for deviations from this formula. S. Tolansky

Recent investigations of the Stark effect. H. Verleger. *Ergeb. exakt. Naturw.* **18**, 99-154(1939).— A review of the Stark effect in the H atom, in rare gases and other atoms and in mols. 182 references. C. D. West

The relative intensities of the Stark-effect components of the helium lines. Lennart Minnhagen. *Z. Physik* **113**, 292-301(1939).—Measurements are reported for the relative intensity ratios of the Stark-effect components of the ortho helium lines $2p\text{-}4q$ (q = *s*, *p*, *d*, *f*). The measurements are made by the canal-ray method in which the canal ray, field strength and direction of observation are at right angles to each other. Measurements are made up to fields of 400 kv./cm.; with the highest fields employed, nearly all the components are resolved. If the total intensity of the *p* components and the total intensity of the *s* components are assumed to be independent of the field for the line group $2p\text{-}4q$, the following is found: $2p\text{-}4s$ exhibits a fall in intensity, $2p\text{-}4p$ shows a rapid growth in intensity with the field strength and this appears to continue beyond the highest field used, $2p\text{-}4d$ loses in intensity when the field rises and $2p\text{-}4f$ quickly attains a max. of intensity such that the intensity of the *s* components remains const. while that of the *p* components falls slightly. The agreement with the theory of Forster is in general not quant. S. Tolansky

The relation between density and shift of the higher lines of alkali series by foreign gases. Chr. Füchtbauer and Gunther Häusler. *Naturwissenschaften* **27**, 658-9 (1939); cf. following abstr.—Fermi's theory (*C. A.* **28**, 3980[7]) of density as well as dielec. effect of a foreign gas on the shift of Na and K lines was further studied. In measuring lines $1s\text{-}14p$ up to $1s\text{-}20p$ of Rb with a Ne pressure of up to 36 atm. (600° abs., relative d. = 15.9) it was found that the violet shift is proportional to the relative d. without any sign of a change of shift to red values. Conclusion: Fermi's assumption of the dielec.-const. influence is erroneous. B. J. C. van der Hoeven

Broadening and displacement of the middle and higher potassium series lines produced by helium at high pressure. Chr. Füchtbauer and W. von Hevesen. *Z. Physik* **113**, 323-33(1939).— Measurements are carried out upon line widths and displacements of 8 potassium lines $1s\text{-}5p$ to $1s\text{-}12p$ in the presence of He to 52 atm. pressure. With $1s\text{-}4p$, only the width was detd. In every case the displacement is exactly proportional to the relative He density, even with the higher series lines. Because of this, doubt is thrown upon the correctness of the Fermi theory, especially upon that part concerned with the influence of the dielec. const. of the perturbing gas. For all observed densities, the max. breadth was attained with the $1s\text{-}4p$ line. Details are given for the behavior of the line widths. The width increases at a rate which is less than linearly proportional to the density. S. Tolansky

The isotope displacement effect in the Tl II spectrum. Peter Kohler. *Z. Physik* **113**, 306-22(1939).—New measurements are reported for the first time for the hyperfine structures of a large no. of lines in the first spark spectrum of Tl. A hollow-cathode discharge is used as a source and a Fabry-Perot interferometer as the high-resolving instrument. Observations are made upon the hyperfine structure isotope displacement. All the sepn. due to nuclear spin (magnetic) and all the isotope displacements can be ordered into a unified term scheme. The observed isotope displacements in the $6s\ ^2S_{1/2}$ term series exhibit good agreement with the inverse cube law for n_a derived from theory. The abs. values of the isotope displacements calcd. by means of the theory of Breit (cf. *C. A.* **27**, 3822, 5640) are too great by a factor of about 2. The displacement of the center of gravity is in the same sense in all the terms, namely the Tl^{203} terms lie deeper than those of Tl^{205}. This is in accord with theoretical prediction. S. Tolansky,

Application to the molecules concerned of the new analysis of molecular spectra. Henri Deslandres. *Compt. rend.* **209**, 612-16(1939); cf. *C. A.* **33**, 1592[1].—D's views are applied to the Raman spectra of PH_3, PD_3, C_6H_6 and C_6D_6. Multiples of his "universal const." 1962.5, such as 1479/(15 × 4), are necessary to secure agreement. C. A. Silberrad

Rotational analysis of the $A'^3\Sigma^+ \rightarrow a^3\Pi$ CO bands. L. Gero and Katalin Loriaczi. *Z. Physik* **113**, 449-61 (1939).—The $c' \rightarrow a$ bands, first found by Asundi (*C. A.* **23**, 5104), have up to now not been studied for rotational structure. The rotational analysis is carried out here. Measurements are made upon the band lines with a dispersion of 1.3 A./mm. Rotational consts. are found and are shown to differ by less than 1.5% from those previously derived from perturbation data alone. This therefore affords strong support for the perturbation method of deriving rotational consts. It is shown that the $a'^3\Sigma^+$

form exhibits a rather large spin splitting. Numerous misprints in previous work are pointed out. An extrapolation results in the following values for the $a'^3\Sigma^+$ term: $B_e = 1.331$ cm.$^{-1}$ and $\alpha = 0.016$ cm.$^{-1}$. S. Tolansky

A $^1\Sigma \rightarrow {}^1\Sigma$ transition of the C_2 molecule. O. G. Landsverk. *Phys. Rev.* **56**, 769–77 (1939).—The 2300-A. band of the carbon arc, previously measured by Heri (*C. A.* **28**, 5333[7]), who attributed it to a C_3 mol., has been accurately measured; photographs were used which were taken on a 30-ft. 34,000 line/in. grating spectrograph with exposures of 2 to 9 hrs. with a 20-amp., 220-v. carbon arc in a low pressure of He. The analysis shows definitely that the structure consists of superposed (0,0), (1,1), (2,2) and (3,3) headless bands of a $\Sigma \rightarrow \Sigma$ transition of C_2 (or possibly C_2^+). Alternate lines are missing in each series, as expected in view of the zero spin of the C nucleus. Most probably the transition is $^1\Sigma_u^+ \rightarrow {}^1\Sigma_g^+$ of C_2. The mol. consts. are very nearly equal for the upper and lower electronic states. They correspond rather closely to the av. values of the same consts. for other known states of C_2. The following values were obtained for the more important consts.: $B_e' = 1.8334$ cm.$^{-1}$, $B_e'' = 1.8223$ cm.$^{-1}$, $\alpha' = 0.0204$, $\alpha'' = 0.0195$, $r_e' = 1.2382$ A., $r_e'' = 1.2419$ A., $\omega_e' = 1748$ cm.$^{-1}$, $\omega_e'' = 1774$ cm.$^{-1}$, $\nu_0^{0,0} = 43{,}227.25$ cm.$^{-1}$. The ω_e values were obtained indirectly from the B and D values, since only one sequence of bands could be analyzed. W. F. M.

Visible and ultraviolet spectra of solid bodies. Georg Joos. *Ergeb. exakt. Naturw.* **18**, 78–98 (1939).—A review of the line spectra of crystals as observed both in absorption and in (fluorescent) emission. 45 references. C. D. West

An apparatus for the study of weak absorption. L. G. Bonner and H. Sponer. *J. Elisha Mitchell Sci. Soc.* **54**, 197–8 (1938).—Structural features of an apparatus for absorption-spectrum studies, especially in the photographic infrared, where large absorption layers are usually required. Colin W. Whittaker

Some optical properties of zinc silicate phosphors. F. A. Kröger. *Physica* **6**, 764–78 (1939) (in English).—When activated with Mn, Zn_2SiO_4 and Zn_2SiO_4-Be_2SiO_4 form solid solns. with Mn_2SiO_4. Solid solns. with less than 50% Mn display, at 25° and −180°, emission bands with max. at 5200 and 6100 A. Emissions are due to electron transitions in the Mn^{++} ion. This same series of solid solns. shows absorption in 3 regions. Excitation in all the absorption regions produces luminescence. **Fundamental absorption of ZnS-MnS and ZnS-CdS-MnS solid solns.** *Ibid.* 779–84 (1939) (in English); cf. *C. A.* **33**, 8483[4].—The fundamental absorption band of ZnS has a long wave-length limit at about 3380 A. Introduction of MnS produces a band with an edge at 3650 A. that is identical with the fundamental band of MnS. Introduction of CdS into ZnS-MnS phosphors displaces the fundamental absorption region of ZnS toward longer wave lengths. G. L. Gerhard

Spectral measurements between 0.2 and 0.5 mm. wave length upon a number of high-frequency insulation materials and oxides. Otto Marr. *Z. Physik* **113**, 415–30 (1939).—An app. is developed for enabling measurements to be made upon the transparency between 200 and 500 . The feeble intensity of the Hg arc can be utilized by using a high-speed spectrometer and a bolometer adapted to the wave lengths studied. From the recorded curves, absorption coeffs., and refraction quotients are derived and the relationship of these to wave length is detd. S. T.

The infrared spectrum and molecular constants of nitric oxide. Alvin H. Nielsen and Walter Gordy. *Phys. Rev.* **56**, 781–4 (1939).—The infrared absorption spectrum of NO has been remeasured under high dispersion with the result that the fundamental at 5.3 μ has been almost completely resolved. The absorption in this region comprises 2 superposed bands arising from a $^2\Pi_{1/2}$, $_{3/2}$ electronic ground state. In the P and R branches a great many of the lines split up into doublets, the components of which belong to these 2 bands, resp. The lines were found to fit the following empirical formulas:

$$\nu_\Omega = {}^3/_2 = 1877.36 + 3.34J - 0.019J^2 \text{ cm.}^{-1}, \text{ where } J = 0, \pm{}^3/_2, {}^5/_2, \ldots$$

$$\nu_\Omega = {}^1/_2 = 1877.00 + 3.42J - 0.019J^2 \text{ cm.}^{-1}, \text{ where } J = 0, \pm{}^5/_2, {}^7/_2, \ldots$$

An expt. curve in percentage absorption against frequency in cm.$^{-1}$ is compared with a theoretical intensity plot of the bands. From the new data some of the consts. have been recalcd., and compared with the results of the electronic band spectra. $I_0 = 1.63 \times 10^{-39}$ g. sq. cm., $r_0 = 1.15 \times 10^{-8}$ cm., $\nu_0 = 1891.3$ cm.$^{-1}$. W. F. Meggers

The adsorption of potential-determining ions. II Influence of the kind and concentration of opposite ions on the adsorption of potential-determining ions. Albin Kellermann and Erich Lange. *Kolloid-Z.* **88**, 341–7 (1939); cf. *C. A.* **32**, 37[8].—A review. G. G.

A hydrogen arc for absorption spectroscopy. A. J. Allen and R. G. Franklin. *J. Optical Soc. Am.* **29**, 453–5 (1939). E. H.

The infrared absorption spectrum of gaseous and liquid sulfur trioxide. L. Gerding and J. Lecomte. *Physica* **6**, 737–62 (1939) (in German); cf. *C. A.* **33**, 3845.—The spectral range investigated extended from 1.5 to 20 μ. Liquid SO_3 was studied in layers 0.01 to 0.2 mm. thick, and the gas in a column 10 cm. long. The gas mol. has a plane symmetrical configuration, with the fundamental frequencies 653, 1068, 1332 and probably 530 cm.$^{-1}$. In the liquid the fundamental frequencies are 530, 653, 1068 and 1378/1402 cm.$^{-1}$. The mols. are apparently assocd. in the liquid, probably forming a polymer contg. 3 mols. of SO_3 arranged in a six-membered ring that is not plane. The bands between 1.5 and 2.5 μ are analyzed in some detail. S. L. Gerhard

Infrared absorption studies of some glycols and ethoxy alcohols. F. T. Wall and W. F. Claussen. *J. Am. Chem. Soc.* **61**, 2679–83 (1939).—The data in the region of 2.8 μ indicate that the ethoxy alcohols can assoc. through the formation of intermol. H bonds, that substituted propanol and butanol can form stable rings and that glycols demonstrate H bonding. A. B. Garrett

The Raman spectra of aluminum and arsenic trimethyl F. Feher and W. Kolb. *Naturwissenschaften* **27**, 615–16 (1939).—The following values for frequencies were found in cm.$^{-1}$: $AlMe_3$ 147 (*m*), 317 (*s*), 457 (*s*), 599 (*w*), 694 (*s*), 687 (*m*), 723 (very *w*), 1231 (*s*), 1261 (very *w*), 1443 (*m*), 2826 (*m*), 2890 (*s*), 2934 (*m*), $AsMe_3$ 238 (*m*), 576 (*s*), 595 (*s*), 786 (*m*), 884 (*m*), 988 (*m*), 1036 (*w*), 1135 (*m*), 1242 (*m*), 1262 (*s*), 1418 (*s*), 2811 (*m*), 2849 (*w*), 2902 (*s*), 3021 (very *s*), 3051 (*w*) and for comparison $SbMe_3$ 188 (*s*), 513 (*s*), 813 (*w*), 1194, 1213 (*m*), 2905 (*s*), 2987 (*w*). If internal vibrations of Me are ignored these trialkyls can be taken as 4 mass bodies that should have 6 basic vibrations. The structure is either in one plane (triangular) with D_{3h} symmetry with 3 basic vibrations expected in Raman spectrum or pyramidal with C_{3v} symmetry and 4 possible Raman vibrations. By attributing frequencies above 1100 per cm. to Me, 7 frequencies are found in both cases. Pyramidal structure is thought likely with disturbance to cause the addnl. lines. Such symmetry disturbance can be due to mutual effects of the mols. in the liquid state or to twisting of the metal-Me bond; in the $AsMe_3$ spectrum doublets are found. The 7th frequency may be attributed to Fermi resonance or to assocn. **Raman spectra of trimethylaluminum etherate.** *Ibid.* 616.—The spectra of Et_2O 454 (*s*), 846 (*s*), 930 (*w*), 1158 (*m*), 1276 (*m*), 1430 (*s*), 1501 (*w*), 2700 (*w*), 2733 (*w*), 2811 (*s*), 2865 (*w*), 2931 (*s*), 2982 (*m*) and of $AlMe_3$-Et_2O 159 (*m*), 202 (*w*), 413 (*w*), 526 (*s*), 573 (*w*), 599 (*w*), 626 (*m*), 725 (*m*), 782 (*w*), 941 (*w*), 906 (*w*), 1003 (*w*), 1071 (*w*), 1098 (*m*), 1195 (*s*), 1340 (*w*), 1461 (*s*), 2783 (very *s*), 2818 (*w*), 2884 (*s*), 2929 (*s*), 2981 (*m*), are compared with that of $AlMe_3$ (preceding abstr.). The etherate spectrum is not additively composed of that of the 2 components. Conclusion: This compd. is a mol. compd. in which Et_2O and trialkyl are closely linked. B. J. C. van der Hoeven

Structure of formaldehyde from electron diffraction. D. P. Stevenson, James E. LuValle and Verner Schomaker. *J. Am. Chem. Soc.* **61**, 2508–10(1939).—Electron-diffraction photographs of monomeric CH_2O made with the use of fast electrons lead to an evaluation of C-O distance of 1.21 ± 0.01 A. From this distance and the accurately known moments of inertia, the C-H distance is 1.09 ± 0.01 A., and the H-C-H angle, 120 ± 1°. George L. Clark

Luminescent materials. II. Fluorescence spectra of zinc sulfide-copper crystal. Yasuo Uehara. *J. Chem. Soc. Japan* **60**, 675–84(1939); cf. *C. A.* **33**, 4522⁴.—The luminescence spectra of ZnS–Cu crystal were taken at −185°, 20° and 150° and the results discussed from the quantum mech. point of view. T. Katsurai

The polarization of the fluorescence of molecules in vapor form and in solution. Franz Suppe. *Z. Physik* **113**, 281–7(1939).—The degree of polarization of anthracene in soln. and in vapor form is detd. for varying concns. and also for varying vapor pressure. The no. of mols. per unit vol. is calcd. for both states of aggregation and the measured degree of polarization is detd., in terms of this. The polarization decreased with the concn. and with the vapor pressure. The degrees of polarization of anthracene dissolved in glycerol and in the vaporized state are practically the same in terms of anthracene mols. per unit vol. S. Tolansky

Sonoluminescence and sonic chemiluminescence. E. Newton Harvey. *J. Am. Chem. Soc.* **61**, 2392–8(1939).—In studying the cause and nature of the phenomenon of sonic chemiluminescence in aq. solns., H. concludes that both chemiluminescence from the activation of dissolved O_2 and luminescence due to elec. discharges assocd. with cavitation can be identified. Sonoluminescence of H_2O and aq. soln. increases in brightness with a decrease in temp., being absent above 40°. The influence, on the sonoluminescence of a large no. of nonmiscible org. liquids, of halogens and of other compds. was detd. R. H. E.

The quantum yield of monochloroacetic acid hydrolysis. R. Nelson Smith, Philip A. Leighton and Wesley G. Leighton. *J. Am. Chem. Soc.* **61**, 2299–2301(1939).—The quantum yield of the monochloroacetic acid hydrolysis is considerably lower than the previously established values, and varies with temp. at 2537 A., from 0.31 at 25° to 0.69 at 69°. It is independent of light intensity and concn. over the ranges studied. A mechanism involving competition between deactivation and decompn. is suggested. P. H. Emmett

The photosynthesis of carbohydrates from hydrated CO_2. II. C. C. Baly. *Proc. Roy. Soc.* (London) **A17**, 445–65; *Chem. Products* **2**, 117–19(1939).—When a surface of NiO contg. ThO_2 in the mol. ratio $1ThO_2$:24NiO adsorbed on kieselguhr is irradiated in the presence of hydrated CO_2 an org. compd. is photosynthesized. The first product of the synthesis, which gives the Molisch reaction after hydrolysis, is unstable and changes slowly at room temp. and rapidly at 60° to a stable compd. This colorless stable compd. can be hydrolyzed by taka-diastase to a reducing sugar and is probably therefore a type of starch. H. C. Thomas

Emission of ultraviolet radiation by, and thermolysis of, ferric azide. Charles Raczy. *Compt. rend.* **209**, 534–6 (1939); cf. *C. A.* **33**, 6162².—Decompn. of $Fe(N_3)_3$ is accompanied by strong ultraviolet emission; the energies of activation are 47 ± 2.5, 33.5 ± 4.5 and 64 ± 5 kg cal.; emission begins at 270° and the transition points are 3.3 ± 4° and 334 ± 5.6°. But if the $Fe(N_3)_3$ has been heated to 310° and cooled emission only begins at 305°, and only 2 energies of activation (34 ± 1 and 75 ± 5) are found. Enclosed in a vessel contg. air or N_2 $Fe(N_3)_3$ explodes at about 200°, the explosion temp. being slightly higher (230°) in N_2; ultraviolet emission is a max. at about 210°, then falling to zero, but reappearing on admission of air. By comparison with results with other azides it is inferred that the processes connected with the energies of activation, 64 and 47 kg.-cal., are independent of the metal, while 33 indicates some different mechanism of thermolysis. C. A. Silberrad

Electric melting of nonferrous metals and alloys. G. H. Clamer. *Metals & Alloys* **10**, No. 10, A32–2(1939).—A review of ten years' progress. 7 references. I. Hartmann

Electrolysis of fused potassium cyanate. A. Perret and J. Riethmann. *Compt. rend.* **209**, 595–7(1939).—When fused KNCO (at 340°) is electrolyzed the first-formed ions react with undecompd. KNCO: at the cathode $KNCO + 2K = K_2O + KCN$ (1), and $2KNCO + K_2O = K_2NCN + K_2CO_3$ (2), (2) being slower than (1). At the anode $2KNCO + 6NCO = 2KN(CN)_2 + 4CO_2 + N_2$ (3). The $KN(CN)_2$ partially polymerizes to K tricyanomelamine. The results were verified by detn. of the amt. of the products formed per Faraday when electrolysis was effected by passage of 1850 coulombs at the anode s. d. of 0.1 amp./sq. dm. C. A. Silberrad

Porous carbon electrodes. II. Oxidation of arsenite. Milton Janeš. *Trans. Electrochem. Soc.* **77**, 13 pp. (preprint)(1940).—By using a porous C anode in the oxidation of $NaAsO_2$ to Na_2AsO_4 it is possible to obtain conversions as high as 99% and to operate at c. ds. greater than 0.1 amp./sq. cm. while substantially 100% current efficiency is maintained. By employing also an air- or O-depolarized C cathode, deposition of metallic As at the cathode is avoided, the cell voltage is appreciably lowered and, as a result of oxidation of arsenite at the cathode, it is possible to obtain considerably more arsenate per unit of current than calcd. on the basis of anodic oxidation alone. Cathodic oxidation may proceed in 2 ways: in the first the oxidation is essentially "chemical," the rate being approx. equal to that obtained when air is diffused through the C in the absence of current; while in the second oxidation proceeds through H_2O_2 formed by the electrochem. reduction of O. In the latter instance it is possible to obtain over 4 times the yield of arsenate per kw.-hr. that can be obtained with Fe electrodes. The anode potential was found to be a linear function of the log of the c. d. at const. ratio of oxidant to reductant concns., and also a linear function of the log of this latter ratio at constant c. d. C. G. F.

Porosity of electrodeposited silver on steel. Frank C. Mathers and Lyle I. Gilbertson. *Metal Ind.* (London) **55**, 295-6(1939). —See *C. A.* **33**, 6768[1]. J. E. D.

The structure of heavy electrodeposits of copper and nickel. J. W. Cuthbertson. *Trans. Electrochem. Soc.* **77**, 19 pp. (preprint)(1940).— C. investigated the structural anomalies revealed from an examn. of a heavy Ni deposit and of several heavy Cu deposits. As regards the Cu specimens, the effect of current interruption was shown to cause semi-discontinuities in the structure, but as to how dangerous this type of defect may prove in practice, it is difficult to say. It is certain that annealing has a deleterious influence on such deposits, greatly increasing the brittleness, as in the case of Ni. So far as could be judged from simple hammering tests, the un-annealed striated deposits were not particularly brittle and in some cases were quite malleable. The un-annealed deposits showed directional variations in the x-ray structure and in the Brinell hardness. Un-annealed Ni specimens cut from the uniform central part of the square cathode, and not incorporating metal from the overgrown edges of the plate, proved to be extremely ductile. Annealing invariably caused rapid loss in ductility and the development of a brittle type of structure. The particular deposit examd. showed wide variations in the crystal grain size from one region to another, but this effect probably would be minimized if suitable precautions were taken in the prepn. of the cathode and throughout the deposition process. Finally, the existence of an intense fiber structure in the electrodeposited Ni, oriented perpendicularly to the cathode, has been demonstrated. C. G. F.

A study of the electrolysis of the sodium cuprocyanide solution. J. V. Petrocelli. *Trans. Electrochem. Soc.* **77**, 9 pp.(preprint)(1940). —The cathode and anode polarization values of Cu in Na cuprocyanide solns. of various concns. were detd. By using Fick's diffusion law as a guide, it is shown how the kinetic electrode potentials can be interpreted from the point of view of the diffusion process as well as from the ratio of Cu to CN ions. Some cathode and anode efficiencies were also obtained to show their dependence on the electrode soln. potential and the diffusion process. C. G. F.

Pretreatment of steel for nickel electroplating. W. Baller. *Schweiz. Arch. angew. Wiss. Tech.* **4**, 289-92 (1938).—The article to be plated is immersed as the anode in 37% H_2SO_4 with a c. d. of 10 amp./sq. dm. until a light-gray surface is obtained. The treatment is repeated until a dark or black color is obtained. A bright surface is next obtained by pickling in a H_3PO_4-H_2CrO_4 soln., and immediately plated in a soln. of 300 g./l. $NiSO_4.7H_2O$, 50 $MgSO_4.7H_2O$, and 17 H_3BO_3 with a c. d. of 3 amp./sq. dm. A. Lloyd Tayler

Nickel plating on cast iron. J. Lemens and J. Dupont. *Ing. chim.* **23**, 73-104, 120-41(1939).— The factors which influence the quality of the deposit were studied: compn. of the bath, temp., pH and c. d. Optimum conditions of the bath are discussed, the app. used and the methods for analyzing the constituents of the bath. A bath of 80% of sirupy industrial phosphoric acid and 20% of H_2SO_4 (53Bé.) gave good results with castings that were difficult to plate. The following formula is recommended for rapid nickel plating: $NiSO_4.7H_2O$ 300-350 g./l.; H_3BO_3 20; NaCl or NH_4Cl 12; H_2O_2 (2%) 1-2 cc./l. For a c. d. of 8-15 amp./sq. dm., the pH should be 4-5 (closer to 4 than to 5) and the bath should be heated to 50°. For cast Fe pieces with rough surfaces the c. d. should be reduced in proportion to the irregularity of the surface. Adherent deposits of a thickness up to 40 microns were obtained. 16 references. M. N. H.

Improvement in quality of metal deposits due to rotation of cathode applies likewise to metal deposits by "displacement." Roberto Piontelli. *Trans. Electrochem. Soc.* **77**, 10 pp.(preprint)(1940).—A careful analysis is made of the various conditions that affect the structure of electrodeposits. Attention is directed in particular to the improved structure of electrodeposits made on rotating cathodes. Metal ppts. obtained by displacement or cementation are likewise investigated, and theoretical considerations lead to the prognostication that rotation of the less noble metal would improve the quality of the cemented metal. Actual expts. fully confirm P.'s deductions. Zn rods were rotated at a peripheral speed of 1.8 m./sec. (5000 r. p. m.) in solns. of Ag, Cu, Pb, Tl and Cd. Compact microcryst., adherent, cemented metal ppts. were obtained. C. G. F.

Pipe protection. Current and voltage requirements for the cathodic protection of bare steel in salt water. Harry J. Keeling. *Am. Gas J.* **151**, No. 4, 54-8(1939).—See *C. A.* **33**, 8507[6]. J. E. D.

Electrical resistance of ferromagnetic amalgams. L. F. Bates and W. P. Fletcher. *Proc. Phys. Soc.* (London) **51**, 778-83(1939).—Amalgams were prepd. by electrolysis; they contain 0.149 to 0.458 g. of Co per 100 g. of Hg. The elec. resistance of thin threads of these amalgams was measured at a no. of temps. from 20° to 340° and compared with the resistance of a similar thread of pure Hg under identical conditions. The results are presented in a series of curves showing $\Delta R/R_T$ as a function of temp., where ΔR is the difference between the resistance of the amalgam thread and the resistance, R_T, of the thread of pure Hg. The type of curve varies somewhat with the concn. of Co, but on the initial heating each shows a sharp change in resistivity in the neighborhood of 340° from a value less than that of pure Hg to a value considerably greater. On subsequent heatings the transition temp. is lower. Two Fe amalgams, containing 0.213 and 0.497% Fe, resp., showed similar changes. The results are compared with those obtained previously for Ni amalgams. W. W. Stifler

Use of sodium-magnesium glass for glass electrodes. A. Pasynskiĭ. *Zavodskaya Lab.* **8**, 803-7(1939).—Glasses containing 27.83-31.3% Na_2O, 5.20-11% MgO and 59-64.69% SiO_2 and no CaO were tested for glass electrodes, measurements being made on the usual potentiometric set-up. The resistance of the electrodes was only 0.1-0.2 megohms. The electrodes acquire the value of the equil. potential very rapidly. For measuring pH of 2.0-9.0 with an accuracy of 0.03-0.05 pH the glass containing Na_2O 28, MgO 8 and SiO_2 64% may be used. Z. Z. K.

Paste compositions for isolated lighting plant lead storage batteries. E. H. Van Kooten and O. W. Brown. *Trans. Electrochem. Soc.* **77**, 9 pp. (preprint)(1940).— Storage batteries are compared in which the pos. plates were made with and without ball-milling the oxides preparatory to making the pastes. The pasted pos. plates were given 2 different curing conditions: one consisted of air-drying at room temp., while the other consisted of a steam vapor treatment. Two methods of preparing neg. pastes are also included which differed in the manner in which the H_2SO_4 was added to the oxide. After 449 cycles, the pos. groups cured at room temp. were essentially of the same capacity whether the oxides were ball-milled or not. Different curing treatments of the pasted pos. plates produced no noticeable difference in capacity when the oxides had not been ball-milled. After 400 cycles the negatives made with dil. H_2SO_4 showed 14% greater capacity than those made by adding H_2O first and later adding H_2SO_4. C. G. F.

The semiconductor theory of the blocking layer and point rectifier. W. Schottky. *Z. Physik* **113**, 367-414 (1939); cf. *C. A.* **33**, 4121[4]. —In the new theory of the unipolar phenomena at the boundary metal-semiconductor, the semiconductor no longer plays the part of a badly emitting electrode of a diode pair in which both glowing electrodes are separated by a potential barrier. Just as in the vacuum of a thermionic valve an electron gas between the electrodes is the carrier. This has current flow properties different from those of the vacuum-gas case. With large layer thicknesses the vacuum analogy fails because of the thermally dissocd. perturbation centers. In this case the semiconductor is much more like a space between 2 thermally emitting electrodes filled with Na vapor. A distinct resistance develops at the boundary metal-semiconductor when the thermal edge density of electrons is

maller than electron density owing to the perturbation centers of the neutral semiconductor. A space charge effect then forms which extends and causes the rectification action. This view is discussed in some detail. A historical survey of the subject is appended.

S. Tolansky

Lead alloys for storage-battery electrodes. Geo. M. Bouton and Earle E. Schumacher (to Bell Telephone Laboratories, Inc.). U. S. 2,170,650, Aug. 22. Electrodes which have good strength and freedom from corrosion embrittlement are formed of Pb alloyed with Ca 0.01–0.15 and Ba 0.005–0.05%. Sr also may be used.

Electric capacitors. Frank M. Clark (to General Elec. Co.). U. S. 2,170,782, Aug. 22. Armatures such as those of Al foil are used with an intervening paper dielectric impregnated with a material such as a mixt. contg. trichlorodiphenylene oxide about 30–45 and pentachlorobiphenyl about 70–55%, the capacity of the capacitor being substantially const. over a temp. range of 25–75°.

Electric rectifier of the sulfide type. Leslie J. Ellison (to International Standard Elec. Corp.). U. S. 2,170,634, Aug. 22. A dry contact metal rectifier of the sulfide type has an electrode formed of a powd. sulfide such as that of Cu mixed with free S, and a heat-resisting impervious cover comprising an asbestos fabric coated with a heat-resisting and elec.-insulating enamel, paint or varnish.

Single-phase mercury-vapor rectifier. Johannes G. W. Mulder (to N. V. Philips' Gloeilampenfabrieken). U. S. 2,170,482, Aug. 22. Various structural and operative details.

Rectifier tubes. Engbert H. Reerink and Mari J. Druyvesteyn (to N. V. Phillips' Gloeilampenfabrieken). U. S. 2,170,634, Aug. 22. An ionic discharge tube having an arc-like discharge comprises an anode, an envelope and a gaseous filling within the envelope having during operation a pressure between a max. value p_{max} and a min. value p equal to $1/2\pi\, p_{max}$, p_{max} being equal to 0.02 mm. of Hg in the case of A and for other gaseous fillings being values which result in a free path of the atoms of identical order of magnitude, and an incandescible cathode having a plurality of parts spaced apart by a distance at least twice the distance at which the entire cathode participates in the emission, the cathode having an electronemitting current capacity whose value is greater than $0.08 + 0.4p/p_{max}$ amp. per sq. cm. of active cathode surface and below the value at which unsatisfactory tube life is obtained.

Electrodeposition of aluminum. Frank C. Mathers and Robert D. Blue. U. S. 2,170,375, Aug. 22. For electrodeposition of Al upon dissimilar metals such as Fe, Cu and Zn, a d. c. is passed between an Al anode and the dissimilar metal as cathode in an electrolyte composed of the reaction product of benzene, an alkyl halide such as EtBr and an Al halide under a layer comprising benzene.

Electroplating with chromium. Morris Brown, Arthur M. Wagner and William Yonkman (to Western Elec. Co.). U. S. 2,172,344, Sept. 12. Bright heavy Cr coatings are deposited from an aq. bath of the chromic acid type, contg. about 250 g. chromic acid and 1–5 g. of sulfate per l., by passing a current of at least 2 amp. per sq. in. to the article to be plated as cathode, maintaining the temp. of the bath at 40–90° and adjusting the cathode to anode area ratio to about 1 to 3 to obtain a smooth deposit.

Electroplating zinc. Harold J. Barrett and Christian J. Wernlund (to E. I. du Pont de Nemours & Co.). U. S. 2,171,842, Sept. 5. Zn is deposited from a soln. contg. 1 g. per l. or less of polyvinyl alc., to produce a bright Zn deposit.

Electrolytic etching of metal plates such as those of zinc for printing. Francis J. Brislee and Reginald Blackburn (to Insulated Cables Ltd.). U. S. 2,172,158, Sept. 5. App. is described, and a method of etching the surface of a metal plate electrolytically which comprises placing the said surface which forms the anode parallel with a flat cathode, which cathode has an effective area so placed and dimensioned that when this area is orthogonally projected on the anode it lies within the boundary thereof, by an approximately constant distance, which distance varies from about one-fourth to one-half the distance between the anode and the cathode.

Electrolytic apparatus for the production of metallic shapes such as copper gaskets. Vernon L. Tannehill (25% to Walter W. Lepper). U. S. 2,171,437, Aug. 29. Various structural, mech. and operative details.

Decomposing nickel-copper mat. I. G. Farbenindustrie A.-G. Brit. 506,841, June 6, 1939. The mat is decompd. with a $CuCl_2$ soln. contg. sufficient $NiCl_2$ to keep the Cu_2Cl_2 formed in soln. From the solns. obtained, Cu and Ni may be sepd. electrolytically and the decompg. solns. may be reformed by treating with Cl from the deposition of Ni the solns. flowing from the Cu electrolysis, with adjustment of the Ni content if necessary.

Electric furnaces. American Magnesium Metals Corp. Brit. 505,617, May 9, 1939. In a furnace construction as described in Brit. 486,559 (C. A. **32**, 8959[9]), resilient members are provided in connection with the struts, and may consist of helical springs acting against adjustable abutments, or may be formed by elastic diaphragms on the shell, or may be in the struts themselves.

Electric arc furnaces. Kurt Schneider and Hermann Schunck (to I. G. Farbenind. A.-G.). U. S. 2,171,435 6, Aug. 29. Various structural, elec. and operative details.

Electric furnace and electrode mechanism suitable for metallurgical operations. Wm. E. Moore (to Pittsburgh Research Corp.). U. S. 2,169,808, Aug. 15. Various structural details.

Electric induction furnaces for melting aluminum and aluminum alloys. Manuel Tama. Brit. 506,980, June 7, 1939. A circular passage of rectangular cross-section filled with metal acts as the secondary of a transformer and passes around a primary coil with an Fe core.

Electric resistance furnaces. Soc. anon. des manufactures des glaces et produits chimiques de St.-Gobain, Chauny & Cirey. Brit. 507,280, June 13, 1939. The radiant heating-element of an elec. furnace has current leading-in members in the form of metallic chambers in which cooling fluid is insulated

Electric furnace heating elements. Siemens-Schuckertwerke A.-G. Brit. 507,846, June 20, 1939.

Electrically heated thermostatically controlled ovens. The General Electric Co. Ltd. and Olliver Wm. Humphreys. Brit. 507,141, June 5, 1939.

Treating gases and liquids with a high-tension electric field, as for separating suspended or emulsified materials. Harry A. Winternute (to Research Corp.). U. S. 2,171,617, Sept. 5. See Brit. 504,396 (C. A. **33**, 7216[2]).

Making holes or recesses in electric insulators of hard material such as porcelain, corundum or diamond. Patent-Treuhand-Gesellschaft fur elektrische Gluhlampen b. H. (to The General Electric Co. Ltd.). Brit. 507,-1., 1939. The insulator is immersed in an electrolyte, e. g., dil. H_2SO_4, a sharply pointed electrode is maintained in contact with its surface and a potential is applied between this electrode and a 2nd electrode arranged in the electrolyte such that an intermittent current flows. Sparking occurs at the point of the pointed electrode to wear away the insulator.

Cathode-ray tube. Geo. F. Brett and Geo. B. Banks (to Radio Corp. of America). U. S. 2,171,970, Sept. 5.

various details of a tube having a screen member with a mica support, a layer of metal such as Au and a fluorescing material such as Willemite on the metal.

Cathode-ray tube. Albert Rose (to Radio Corp. of America). U. S. 2,171,224, Aug. 29. A process of forming a photoconductive surface on an electrically conductive base such as a metal sheet involves depositing on the base a layer of refractory oxide such as oxide of Al or Zr, exposing the layer to the vapor of an alkali metal such as Cs and heating the base and assocd. layer of deposited alkali metal to photosensitize the layer, and baking the materials to impregnate the layer with the alkali metal and until the layer shows negligible photoelec. emission and negligible electrostatic storage.

Cathode-ray tube and associated apparatus for voltage measurements. Geo. M. Koch (to Radio Corp. of America). U. S. 2,171,216, Aug. 29. Various structural, elec. and operative details.

Cathode-ray discharge device. Wm. H. Painter (to Radio Corp. of America). U. S. 2,170,663, Aug. 22. Structural details.

Secondary electron-emitting electrodes such as those for amplifiers. Willem J. H. Schreinemachers (to N. V. Philips' Gloeilampenfabrieken). U. S. 2,171,227, Aug. 29. A method of making secondary electron-emitting electrodes having high secondary electron emissivity involves producing a cloud of oxide of an alk. earth metal or MgO by burning an alk. earth metal or Mg in an oxidizing atm. and exposing a metal core body such as a cold Ni sheet to the cloud of oxide to form a layer of the oxide on the core body.

Photoelectric cathode. Paul Gorlich (to Zeiss Ikon A.-G.). U. S. 2,172,164, Sept. 5. An oxidized Cu or Ag base carries a layer of alkali metal such as Cs and a thin overlying layer of Pb, Sb or Bi.

Cathode for electron-discharge devices. Erich Wiegand (to Allgemeine Elektricitats-Ges.). U. S. 2,171,249, Aug. 29. A cathode support such as one of an alloy contg. Cu 95% or more and Ni 5% or less is provided with an oxide coating. Ca, Si or Ca boride may be used as a deoxidizing agent.

Glow cathode for heavy-duty discharge devices. Hans Kolligs and Robert Lauter (to Siemens & Halske A.-G.). U. S. 2,172,207, Sept. 5. A cathode is formed of a hollow metal tube such as one of Ni or Cu carrying a layer of sintered particles of Ni, Cu, Ag or Fe and an overlying electron-emitting coating contg. an alkali or alk. earth metal.

Arc-discharge device (with a mercury pool as cathode) suitable for controlling welding apparatus. Ernest G. Bangratz (to Westinghouse Elec. & Mfg. Co.). U. S. 2,172,185, Sept. 5. An auxiliary starting device such as a starting electrode is immersed in a Hg-pool cathode during normal operation of the device, and the Hg pool has a surface freely exposed to the arc from the anode, and damping means for waves on the freely exposed surface of the Hg, such as a mesh screen, is located entirely below the surface.

Luminescent tubes containing neon. Russell B. Leonard and Wm. E. Leonard. U. S. 2,171,705, Sept. 5. Various details of a device contg. Ne under reduced pressure and provided with a capsule contg. a reserve supply of gas which is liberated by rupture of the capsule when abnormally heated owing to depletion of the original gas supply.

Fluorescent or luminescent lamp compositions. Thomas M. Cortese (to Colorescent Laboratories, Inc.). U. S. 2,172,046, Sept. 5. A liquid compn. for coating tubes, bulbs or the like, such as those of elec. lamps and which may be formed of glass, contains about 1.5 g. nitrocellulose having a low viscosity of 50–100 sec., about 0.5 g. of camphor per 100 cc. of a solvent such as AmOAc, and also about 50 g. of powd. fluorescent or luminescent material such as Ca tungstate per each 100 cc. of the liquid binder.

Fluorescent lamp. Samuel Ruben. U. S. 2,170,066, Aug. 22. An ionic discharge lamp comprises a glass vessel filled with gas under low pressure such as Ne and Hg and contg. a mat of glass-wool fibers coated with a fluorescent material such as Cd silicate.

Electric incandescent lamp. Ernst Friederich and Wilfried Meyer (to General Elec. Co.). U. S. 2,170,683, Aug. 22. An incandescible body such as one of UO_2, TiO_2, V_2O_5, Cb_2O_5 or Ta_2O_5 comprising a rare oxidizable metallic oxide, which is conductive at ordinary temps., is used with an atm. comprising inert gas and a small amt. of O sufficient to cause the incandescible body to retain its electronic cond. at temps. of about 2000° but insufficient to cause conversion of such oxide to a higher form of nonconductive oxide.

5—PHOTOGRAPHY

E. R. BULLOCK

Proposal for a new tripack system for color cinematography. I. Guido Jellinek. *Progresso fot.* **45**, 337–8, 341 (1938); cf. *C. A.* **33**, 6735⁸.—In a tripack system for making sepn. negatives the blue-sensitive film is exposed through the support, the green-sensitive film, backed with a yellow filter layer, is exposed through the support, and the red-sensitive film is exposed with its emulsion in contact with that of the green-sensitive film. In order to focus all 3 images sharply, there is placed behind the lens a banded or zoned blue and yellow filter which has cemented on the yellow area a piece of glass thick enough to throw the focus back by a distance equal to the thickness of a film support. **II.** *Ibid.* 372, 375–6.—In making a motion-picture film color print from sepn. negatives a pos. film is first exposed behind the green record negative and color-developed to a magenta image. The Ag is oxidized to AgI, the film is exposed behind a superposed combination of the green and blue record negatives, and the image developed yellow. The Ag is oxidized again and the film is exposed 4 times through different combinations of negatives and is color-developed to a cyan image. The complex arrangements of the blue and red record exposures are intended to cancel out the effect of the absorption of the exposing light by the previously developed color images in the film. C. Ehrenfried

Behavior of the photographic emulsion upon illumination with very weak ultraviolet light. H. W. Kölle. *Fundamenta Radiologica* **4**, 115–31(1939).—The behavior of I. G. Farbenindustrie Emulsion 2000 toward very weak light of wave length 254 mμ is described. Especially pure monochromatic radiation was obtained by quadruple dispersion. A light path of 13.4 m. was used to reduce the intensity of radiation. It was found that in the range from 1×10^6 to 1×10^3 quanta per 0.0196 sq. mm., for times from 10^{-1} to 10^4 sec., the "quantum yield" for threshold ds. was practically const. Therefore, for this region the photographic plate can be used as an integrating receiver for wave length 254 mμ. If regions of higher energy are to be compared, this is possible only by means of a d. surface which is to be detd. for each emulsion under const. conditions of illumination and development. For very small energies, the quantum yields were higher, the longer the radiation acted at correspondingly lower intensities. The emulsion investigated proved to be an excellent qual. integrating receiver. For quant. applications, it is necessary, however, to have recourse to an experimentally detd. d. surface. C. H. Evans

Photoconductance of dye-sensitized silver bromide and the mechanism of dye sensitization. Naoto Kameyama and Tutomu Hukumoto. *J. Soc. Chem. Ind. Japan* **42**, Suppl. binding, 244(1939); cf. *C. A.* **32**, 2837⁷.—K. and H. found that the photoconductance of pure, fused AgBr (in the form of thin plates) shows a max. at 454–458 mμ, and is extremely small at 520 mμ. Sensitization with erythrosin, after first converting the AgBr into the "Ag-body," produces an addnl. max. of the photoconductance

at 560 mμ. Correspondence between the spectral ranges of photographic sensitivity and photoconductance is also shown with cryptocyanine and dicyanine. Conclusion: The latent image of dye sensitization is formed by the elevation of electrons to the conduction band by the energy absorbed by the adsorbed sensitizing dyes, the latter functioning as transmitters of energy. E. R. Bullock

A reversal phenomenon on photolytically formed silver (sodium nitrite bleach-out process). Hans Arens *Z. wiss. Phot.* **38**, 28–37(1939).—Using an otherwise strong v solarizing AgBr emulsion with the addn., before coating, of 0.5 g. of $NaNO_2$ per 100 cc., A. has further investigated the nitrite bleach-out effect (*Z. Elektrochem.* **32**, 498; *C. A.* **23**, 5122). This effect is obtained on darkening the plates by a heavy uniform exposure, washing thoroughly and drying, and then reexposing behind a positive On developing, either chemically or physically, A. now observes a reversal which corresponds with the direct effect. He finds also that the free Ag produced, alike without or after development, tends to increase with increasing exposure, although the no. of darkened particles becomes less in the bleach-out, or reversal, region. He concludes, therefore, that a coalescence of the Ag which seps. in the presence of nitrite, to larger particles, takes place during the 2nd exposure. E. R. Bullock

Coote, Jack H.: Making Colour Prints: Practical Photographic Methods. London: Focal Press. 123 pp. 5s.

Multilayer filter for use in color photography. Karl Schinzel (to Eastman Kodak Co.). U. S. 2,172,262, Sept. 5. A color filter comprises a support and 3 gelatin-Ag halide emulsion layers carried by the support, the layers being differently color sensitive, and substantially colorless filter layers absorbent of ultraviolet between the middle layer and each of the other 2 layers, the ultraviolet filter layers being insol. in ordinary photographic baths.

Photographic developers. Alfred Müller (to Agfa Ansco Corp.). U. S. 2,172,216, Sept. 5. A developing agent such as hydroquinone is used with an alkali metal salt of meta- or pyro-phosphoric acid, and with an aliphatic N-contg. polycarboxylic acid such as tetramethyldiaminomethanetetracarboxylic acid, to prevent "lime fogging."

Hardening photographic gelatin and emulsion layers. Cyril J. Staud and Grafton H. Keyes (to Eastman Kodak Co.). U. S. 2,172,300, Sept. 5. An acetal of an aliphatic aldehyde, such as glyoxal tetraethylacetal, is used as a hardening agent (suitably about 0.4% with a 5% gelatin soln. for an antihalation backing).

Antihalation layers for photographic materials. Olaf F. Bloch (to Ilford Ltd.). U. S. 2,171,911, Sept. 5. See Brit. 499,768 (*C. A.* **33**, 4894[6]).

Coloring photographic materials such as gelatin-silver halide layers. Béla Gáspár. U. S. 2,172,307, Sept. 5. A method is used which comprises dissolving, within the colloid used for the formation of a layer of photographic material, a sol. deriv. of an azo dye, such as a bisulfite addition compd., which contains an O or N atom linked to a C atom of the dye molecule and the radical of a polybasic acid in hydrolyzable linkage with the O or N, and splitting off the azo dye from the dissolved deriv. by hydrolysis. Numerous examples are given.

Coloring photographic materials such as gelatin-silver halide layers. Béla Gáspár. U. S. 2,172,308, Sept. 5. A method of coloring a photographic material with an azo dye involves incorporating into the colloid used a water-insol. azo dye component having an inorg. atom, such as a bisulfite addition compd., and which contains O or N linked to a C atom, and synthesizing the azo dye within the colloid from the insol. component, a hydrolyzing agent being used for splitting off the insol. dye component from the sol. deriv.

Photosensitive device suitable for testing purposes. Earl D. Wilson (to Westinghouse Elec. & Mfg. Co.). U. S. 2,172,232, Sept. 5. A photosensitive device comprises a Cu oxide having a translucent conductive film such as Ag, Au or Pt thereon, a natural resin layer such as rosin on the conductive film, and a conductive material such as an alloy of low m. p. fused to a certain portion only of the natural resin layer extending through the resin layer and making elec. contact with the translucent conductive film, the conductive film and natural resin layer having sufficient area clear of the alloy for the passage of light for the actuation of the device

Photographic desensitizing. Walter Dieterle and Sebastian Gassner (to Agfa Ansco Corp.). U. S. 2,172,192, Sept. 5. A process of desensitizing a light sensitive Ag halide emulsion comprises treating the emulsion with an aq. soln of an ether or thioether, the ether atom of which is linked on one side to an anthraquinone nucleus and on the other side to a member from the class consisting of aliphatic radicals, aromatic radicals, and heterocyclic radicals, the compd. contg. at least one of the groups SO_3Na and SO_3K. Cf. *C. A.* **33**, 641[4].

Masking photographic color-separation negatives. Wm. J. Wilkinson (to Miehle Printing Press and Mfg. Co.) U. S. 2,170,883, Aug. 29. A process of masking a set of color-sepn. negatives of a subject involves making a positive-transparency from one of the color-sepn. negatives, opaquing all tone portions of the positive-transparency leaving all whites transparent thereby providing an opaqued master-mask, coating the emulsions of a plurality of the color-sepn. negatives each with a light-sensitive stratum, registering the master-mask on the strata in turn, and while so registered exposing the corresponding stratum to light through the master-mask, and developing and rendering the exposed parts of the strata opaque, whereby each such treated color-sepn. negative has its own individual mask affixed to its emulsion in proper register.

Reproduction of graining such as that of wood by a photographic method. Frank L. Lee. U. S. 2,171,578, Sept. 5. Various operative details for matrix plate production.

Blueprint coating compositions. Garnet P. Ham (to American Cyanamid Co.). U. S. 2,172,319, Sept. 5. A light-sensitive ferric salt such as ferric NH_4 oxalate is used with a sol. ferricyanide such as that of K or Na and a quaternary NH_4 compd. such as trimethylbenzylammonium hydroxide which serves as a sensitizer. Cf. *C. A.* **33**, 851[9].

Toning photographic prints. Francis H. Snyder and Henry W. Rimbach (to Technico, Inc.). U. S. 2,171,609, Sept. 5. In toning a Ag photographic print with replacement of the Ag image at least in part with a CdS image, the print is immersed in an aq. treating bath contg. a sol. Cd salt, a sol. ferricyanide and a hydroxy aliphatic acid such as citric acid capable of forming a complex metal-acid ion, and the Ag compd. is removed from the print by dissolving it in a soln. of a sol. thiosulfate or thiocyanate, and the print is washed and then immersed in a soln. contg. a sol. sulfide. Numerous similar treatments are described.

Photographic safelight. Earl M. Lowry (to Eastman Kodak Co.). U. S. 2,172,249, Sept. 5. A light filter is used which absorbs red and infrared light, comprising a colloidal medium such as gelatin in which is dispersed Cu acetate or Ni acetate and an ethanolamine

6—INORGANIC CHEMISTRY

W. C. FERNELIUS AND L. L. QUILL

Action of ammonia gas on anhydrous or hydrated magnesium chloride. Léon J. Olmer and Marie Louise Quinet. *Compt. rend.* **209**, 513–16(1939).—$MgCl_2.6NH_3$, obtained by passing NH_3 over anhyd. $MgCl_2$, is more conveniently obtained by passing dry NH_3 into a soln. of $MgCl_2$ in anhyd. EtOH, when it is pptd. in white octa-

he a, insol. in C_6H_6 or Et_2O, and stable in a sealed tube, but slowly decompd. in dry air. In a vacuum at 15° it passes into $MgCl_2.4NH_3$, at 111° into $MgCl_2.2NH_3$, and at 800° to $MgCl_2$ with no trace of nitride. A convenient way of prepg. $MgCl_2$ is therefore to dry $MgCl_2.6H_2O$ at 100°, thus forming $MgCl_2.4H_2O$; this is calcined producing $MgCl_2$ contg. 25% MgO; the $MgCl_2$ is dissolved out by EtOH, pptd. by NH_3, the ppt. washed with C_6H_6 and calcined. The action of NH_3 on $MgCl_2$ dissolved in EtOH varies with temp. and concn.; at 70° only MgO and NH_4Cl are formed; at 20° and concn. below 6% $[Mg(NH_3)_6H_2O]Cl_2$ is obtained, which on calcination gives $MgCl_2.MgO$; with concn. above 6% between −20° and +20° $[Mg(NH_3)_5(H_2O)_3]Cl_2$ (cf. Spacu and Ripan, *C. A.* **17**, 2090). MeOH and PrOH can be used in place of EtOH, but less satisfactorily. C. A. Silberrad

Recent developments in the chemistry of the boron hydrides. I. The structure of the boron hydrides. A J E. Welch. *Chemistry & Industry* **1939**, 869–72. E. H.

Graphite and graphite compounds U. Hoffmann. *Ergeb. exakt. Naturw.* **18**, 229–56(1939). A review of the properties and structure of graphite and its compds. with alkali metals (ideal formulas C_8M and $C_{16}M$); with F (CF); with O (C_2O); and with inorg. O acids ($C_{24}HSO_4.2H_2SO_4$). C. D. West

Systematic study of affinity. XC. Germanium phosphide. Maria Zumbusch, Max Heimbrecht and Wilhelm Biltz. *Z. anorg. allgem. Chem.* **242**, 237–48(1939); cf. *C. A.* **33**, 9062[2]. Ge phosphide, GeP, was formed by heating fine Ge with an excess of P to temps. of 400° or more in an evacuated tube. The reaction is incomplete. Ge was detd. in the reaction products by pptg. GeS_2 by H_2S from weak HCl solns. in the presence of reducing agents, to prevent formation of S. X-ray analysis showed that products contg. Ge and P in the at. ratio 1:1 give a pattern distinct from both free Ge and free P. This conclusion is confirmed by tension measurements on mixts. heated to definite temps. The heats of formation are estd.: 4Ge (solid) + P_4 (gas) → 4GeP (solid) + 37 kg.-cals.; Ge (solid) + P (white) → GeP (solid) + 6 kg.-cals. **XCI. Zirconium sulfides.** Erich F. Strotzer, Wilhelm Biltz and Karl Meisel. *Ibid.* 249–71.—Zr sulfides were prepd. by heating metallic Zr with excess of S to about 700° in a closed tube. The Zr in the product was detd by oxidation to ZrO_2 in a stream of air. Five products of the general formula ZrS_n were reported: Z S_3, ZrS_2, Zr_2S_3, and 2 lower sulfides in which n = 0.75 and 0.20–0.33 resp. The description of the lower sulfides is vague; presumably they are solns. of other sulfides in excess S. Pure ZrS_2 was prepd. by the action of H_2S o... $ZrCl_4$ obtained from ZrO_2 in a tube protected against air and moisture. ZrS_3 was made from ZrS_2 by heating with S / ZrS_2 nd ZrS_3 were examd. by tension, x-ray and density methods. The heat of reaction, ZrS_2 (solid) + S (rhombic) → ZrS_3 (solid) + 8.5 kg.-cals., was detd. ZrS_2 is orange-red, ZrS_2 brown, and Zr_2S_3 black with a bluish sheen. The lower sulfides are black to gray. ZrS_2 is saltlike in nature; it shows the reactions of a salt, and its mol. vol. can be calcd. from the at. vols. of its ions. ZrS_3 is regarded as a polysulfide. The lower sulfides are "half-metallic," and approach metals in such properties as color or cond. J. H. Reedy

Fluorination of phosphorus trichloride. Harold S. Booth and Abe R. Bozarth. *J. Am. Chem. Soc.* **61**, 2927–34(1939); cf. *C. A.* **27**, 5018. The chlorofluorides of P were prepd. by (*a*) the Swarts reaction between PCl_3 and SbF_3 in the presence of $SbCl_5$ as a catalyst, (*b*) the reaction between PCl_3 vapor and hot CaF_2, and (*c*) the reaction between PCl_3 and PF_3 in a hot tube. $PFCl_2$ b. 15.85 ± 0.05°, heat of vaporization 5950 cal./mol., Trouton's const. 20.7, m. −144.0 to −144.4°, mol. wt. 122. PF_2Cl b. −47.3°, heat of vaporization 4200 cal./mol., Trouton's const. 19.1, m. −164.8°, mol. wt. 105.5 PF_3 b. −101.1°, heat of vaporization 3 89 cal./mol., Trouton's const. 20.3, m. −151.5° mol. wt. 89. Vapor pressures are tabulated. A. B. Garrett

The fluorination of phosphorus tribromide. Harold S. Booth and Spencer G. Frary. *J. Am. Chem. Soc.* **61**, 2934–7(1939).—The compds., PBr_2F, $PBrF_2$ and PF_3, were obtained in the fluorination of PBr_3 in the vapor state with CaF_2 at 140° or by the action of SbF_3 at 70° and 170° with Br as a catalyst. For $PBrF_2$ and PBr_2F, resp., mol. wts. are 218, 149; m. −115.0°, −133.8°; b. 78.4, −6.1; heats of vaporization 7624, 5721; crit. temps. 254, 113; Trouton consts. 21.7, 22 3; d_0 2.1810, −. A. B. Garrett

The fluorination of phosphoryl trichloride. Harold Simmons Booth and Frederic B. Dutton. *J. Am. Chem. Soc.* **61**, 2937–40(1939).—The fluorination of $POCl_3$ by the Swarts reaction and in the vapor phase by CaF pellets yielded POF_3, POF_2Cl and $POFCl_2$. Resp. consts are b. −39.8°, 3.1°, 52.9°; f. p. −39.4°, −96.4°, −80.1°; liquid d_0 −, 1.6555, 1.5931; gas d. 104.0, 120.5, —; crit. temps. 73.3°, 150.6°, —; crit. pressures (atm.) 41.8, 43.4, —; heats of vaporization 5030, 6090, 7403; Trouton's consts. 21.6, 22.03, 22.7. Vapor pressures are tabulated. A. B. Garrett

Columbium and tantalum. Introduction. P. Klinger. *Tech. Mitt. Krupp Forschungsber.* **2**, 171–3(1939). Cb and Ta form with C stable carbides so that they prevent grain disintegration in austenitic Cr-Ni steels if added to rustless steels in small amts.; besides, they produce a slight increase in tensile strength and toughness. Because of the difficult sepn. of the 2 elements they are added to steel as ferrotantalocolumbium, never as ferrotantalum or ferrocolumbium. Methods of sepn. of Cb and Ta are critically discussed. Twenty references. **Determination and separation of columbium and tantalum in steel by precipitation with benzenearsonic acid or sodium bicarbonate with addition of hydrogen peroxide.** H. Lucke and J Daublander. *Ibid.* 174–8.—Two methods for sepn. of Cb and Ta are described, one is based on pptn. of Ta in H_2O_2-contg. H_2SO_4 soln. with benzenearsonic acid; Cb stays in the soln, from which it is pptd. later after destruction of the H_2O_2 by benzenearsonic acid. The other method seps. the acids of the earth metals in H_2O_2-contg. H_2SO_4 soln. with $NaHCO_3$; Ta ppts first and Cb is sepd in the filtrate with H_2SO_4. A third method describes the simultaneous sepn. of Cb and Ta in steel by detg. the SiO content at the same time. Four references. **Photometric determination and separation of columbium, tantalum and titanium in steel and iron alloys.** P. Klinger and W. Koch. *Ibid.* 179–85.—See *C. A.* **33**, 9186[8]. **The spectrum-analytical determination of columbium and tantalum in high-alloy steels.** O. Schlessmann. *Ibid.* 185–90.—The detn. by the emission spectrum of these elements is very satisfactory, the min. content which can be detd. for Cb is 0.1%, for Ta 1%. The Cb lines used in the spectrograph are 3697.85, 3713.06 and 3726.25. For Ta the lines are 2675 and 2908.9 and Fe 2689; for visual observation alone line Ta 6485.36 is the most suitable. The exact procedure both for detection and detn., is described in full, and comparative spectrograms show the clarity of the lines obtainable with austenitic steels, with and without Cb. The time required for a detn. is about 2–3 hrs. Fifteen references. M. Hartenheim

Alkali uranates, columbates and vanadates prepared by a dry method. Henri Guiter. *Compt. rend.* **209**, 561–2(1939). U_3O_8, Cb_2O_5 and V_2O_5 were fused with alkali carbonates or (V_2O_5 only) alkali sulfates, and the compn. of the product was detd. by wt. and amt. of CO_2 or SO_2 evolved. In this way U_3O_8 and carbonates of Li, Na, K, Rb and Cs gave uranates of compn. M_2UO_4 as difficultly fusible powders; they are, resp., pale rose brown, orange, vermilion and pale vermilion; all are decompd. by acids. Cb_2O_5 similarly formed with carbonates of Li, Na or K, $Cb_2O_5.5M_2O$; with those of Rb and Cs, $Cb_2O_5.4M_2O$. All are sol. in H_2O, those of K, Rb and Cs being deliquescent; all are easily fusible and decompd. by acids. V_2O_5 yielded with carbonates of Li or Na MVO_4, but with those of K, Rb or Cs $M_4V_2O_7$. Fused similarly with alkali sulfates $4Li_2O.5V_2O_5$, $2Na_2O.3V_2O_5$, $2K_2O\ 3V_2O_5$, $Rb_2O.2V_2O_5$ and $Cs_2O.2V_2O_5$ were obtained. All are easily sol. in H_2O, those of Rb and Cs being deliquescent. C. A. Silberrad

Halogen sulfides and halogen selenides of mercury. A. Baroni. *Atti accad. Lincei, Classe sci. fis. mat. nat.* **29**, 76-9(1939).—Double salts of HgS with $HgCl_2$, $HgBr_2$ and HgI_2 are known to exist. B. has prepd. corresponding compds. with HgSe; the compds. $HgSe.HgCl_2$, $HgSe.HgBr_2$, $HgSe.HgI_2$, $2HgSe.HgCl_2$, $2HgSe.HgBr_2$ and $2HgSe.HgI_2$ are shown to be formed when H_2Se dild. with N_2 is passed through the above Hg halides in dil. soln. The ppt. was collected on a film of collodion and examd. by means of electronic rays as previously used in solving problems of polymorphism and isomorphism (*Z. Krist.* **92**, 210(1935); *C. A.* **32**, 8234[3]). A. W. Contieri 1 2

The chemistry of organic metallic complexes and coloring matters. A. Wahl. *Rev. gén. mat. color.* **43**, 321-5 (1939).—A review and discussion of these substances from the point of view of a new classification based on secondary valences, which is called complexocyclics; this group an addnl. one to Beilstein's classifications: acyclics, carbocyclics, heterocyclics. Among these substances are cited Cu glycine, β-aminopropionic acid, metal derivs. of *o*-hydroxyazo compds; the Neolan, Inochrome and Palatin dyes, the Cu compd. of Orange 2, and phthalocyanines. 3 references. Halsey E. Silliman 3

The question of the existence of salts of hexamethylenetetramine in solution. Anna Rattu. *Ann. chim. applicata* **29**, 221-5(1939). From a series of detns. of the f.-p. lowering of solns. of $N_4(CH_2)_6$ with acids, it is shown that the immediate reaction on addn. of acid is one of addn. Later the hydrolytic action of the H^+ ion becomes predominant, with increasing hydrolysis according to the reaction $N_4(CH_2)_6 + 4HCl + 6H_2O = 4NH_4Cl + 6CH_2O$. A. W. Contieri 4

Nickel complex salts containing quadrivalent and sexivalent central atoms. H. Glaser and P. Pfeiffer. *J. prakt. Chem.* **153**, 300-12(1939); cf. *C. A.* **33**, 1389. $Ni(ClO_4)_2$ forms with ethylenediamine and its mono- and dialkyl derivs. violet products, but with trialkylated diamines amorphous basic Ni salts, contg. no N. Upon dehydrating the aquo salts obtained in this way, there is a sharp color change from violet to orange, which indicates that the H_2O group were attached directly to the central atom. The type formula of these salts is therefore assumed to be $[Ni_a(OH_2)_2]X_2$. The following compds. are described: (1) *Triethylenediamine nickel perchlorate* is formed by reaction of $Ni(ClO_4)_2$ with $C_2H_4(NH_2)_2$; it forms red crystals, sol. in hot water and in hot MeOH; the dry salt explodes upon ignition. Violet plates are also obtained if the product is warmed in excess water and the soln. evapd. at room temp. (2) *Diaquo-diethylenediamine nickel perchlorate* is formed by reaction of $Ni(ClO_4)_2$ with ethylenediamine monohydrate; it is a deep-blue soln., decompg. upon heating; upon evapn. at room temp. violet crystals are obtained; at 100°, the product loses H_2O, leaving an orange powder; it explodes violently upon ignition. (3) *Trimonoethylethylenediamine nickel perchlorate* is formed upon adding a soln. of $Ni(ClO_4)_2$ in MeOH to monoethylethylenediamine; it forms violet-blue crystals, slightly sol. in cold water and in cold MeOH, recrystd from hot solns. (4) *Duquo-di-sym. diethylethylenediamine nickel perchlorate* is prepd. by action of concd. $Ni(ClO_4)_2$ on concd. diethylethylenediamine; it forms violet-to-blue crystals, sol. in hot water; sol. in hot MeOH (orange), giving grayish blue ppt. upon cooling; it loses water at 100° (orange), changing back to violet in contact with moist air; it explodes upon ignition. (5) *Di-unsym. diethylethylenediamine nickel thiocyanate* is prepd. by mixing unsym. diethylethylenediamine Ni perchlorate in MeOH with KSCN, heating to 100°, and crystg.; it forms violet-blue crystals, anhyd., dried on clay disk in air; it is sol. in pyridine, slightly sol. in alcs., almost insol. in Me_2CO or $CHCl_3$; it loses water at 160°, forming $Ni(C_2H_4(NH_2)_2.NEt_2)(SCN)_2$; it is decompd. by water, more or less sol. in Me_2CO and in pyridine. J. H. Reedy 5

7—ANALYTICAL CHEMISTRY

W. T. HALL

American Society for Testing Materials, Methods of Chemical Analysis of Metals, 1939. Cf. *C. A.* **31**, 4223[3]. Methods adopted or revised since 1936 are given for the chem. analysis of steel, cast iron, open-hearth iron, wrought iron and ferro-alloys; the sampling of ferro-alloys; and quant. spectrochem. analysis of high-grade pig Pb and of Zn-alloy die castings. G. G. 6

Thermic behavior of compounds which are important in analytical chemistry. I. $CaC_2O_4.H_2O$. J. Kruttinsons. *Z. anal. Chem* **117**, 330-2(1939). For detg. Ca it is often recommended to weigh as $CaC_2O_4.H_2O$ after drying an hr. at 105°. The results of some 16 expts. show that no serious error is introduced if the temp. of the drying oven rises to even 140° although the ppt. shows a distinct vapor pressure even at 105° and loss of wt. becomes noticeable if the drying is continued for several hrs. at 105°. W. T. H. 7

Potentiometric measurements in practice: the use of a new instrument. František Poupě. *Chem. Listy* **33**, 306-8(1939). With Pt or Ag capillary electrodes and with a compensating voltmeter P. was able to study potentiometric titrations under conditions in which the usual methods were not dependable. Frank Marečh 8

Utilization of capillary properties of filter paper in analysis. A. A. Kornfskiĭ. *Zavodskaya Lab.* **8**, 688-92(1939). —By means of NH_4CNS and pyridine it is possible to detect Fe^{+++}, Cu^{++} and Co^{++} in one soln. Fe occupies the lowest portion, Cu the middle, and Co the upper portions of the filter paper. In this manner it was possible to detect 1 γ Fe^{+++} in 0.2 ml. soln. in the presence of 500 γ Cu^{++} (Co does not interfere), 8 γ Cu^{++} in the presence of 200 γ Fe^{+++}, and 10 γ Co^{++} in the presence of 200 γ Fe^{+++}. With $FeCl_3$ it is possible to detect 4 γ $Fe(CN)_6$ in the presence of 1000 γ CNS^- in 0.2 ml. soln. B. Z. K. 9

Colorimetric titration and its application in the metallurgy of aluminum. III. P. Urech. *Helv. Chim. Acta* **22**, 1023-36(1939); cf. *C. A.* **33**, 1155[4]. —Excellent results were obtained with the Zeiss Pulfrich photometer in detg. very small quantities of Si by means of the yellow color produced with $(NH_4)_2MoO_4$ in the presence of acid. Full directions are given for carrying out the analysis. The procedure is applicable to detg. Si in alloys or in clay. W. T. H.

Use of potassium chromate as indicator for the titration of chlorides with silver nitrate. A. J. Berry and J. E. Driver. *Analyst* **64**, 730-4(1939). When neutral alkali chlorides are titrated by Mohr's method (*Ann. Chem.* **97**, 335 (1856)), very accurate results are obtained and up to pH 5.5 the error does not exceed 3 parts in 1000. At greater acidity, the results are high. The presence of NH_4 salt has a slight effect upon the accuracy, particularly when the acid constituent is weak, but NH_4Cl solns. can be titrated by Mohr's method and the results are only about 0.1% higher than when phenosafranine is used as indicator. When HCl soln. is neutralized with $CaCO_3$, and the halide detd. by M.'s method, the results are about 0.2% higher than when Na_2CO_3 is used for neutralization. The solns. used in the titrations described were about 1.5×10^{-3} molar in CrO_4^{--}. Mohr's method is likely to remain a standard method of analysis. W. T. H. 10

***p*-Nitrobenzyl cyanide, as an indicator.** Ladislaus Spitzer. *Ann. chim. applicata* **29**, 219-20(1939).—*p*-Nitrobenzyl cyanide is yellow below pH 11.4; it turns to orange-red with increasing pH up to pH 12.9, beyond which there is no further color change. A. W. C. 11

Use of iodo derivatives of methylene blue in quantitative analysis. L. M. Kul'berg. *Zavodskaya Lab.* **8**, 421-3 (1939). The iodo derivs. of methylene blue were used to detect Ag, Hg, Sn, sulfide, sulfite and thiosulfate ions. In each case a drop of the reagent is placed on filter paper and

tu. a drop of the moderately acid test soln. A blue coloration indicates the presence of the reacting ion. The quantities detd. were 0.002 γ Ag, 0.021 γ Hg and 0.6 γ Sn. The reagent also reacts with $Hg(CN)_2$ and freshly pptd. HgCl. The sensitivities of the reagent for sulfide, sulfite and thiosulfate ions were, resp., 0.025, 0.050 and 0.020 γ. The reagent is prepd. by mixing 1% aq. soln. of methylene blue with an excess 0.1 *N* soln. of I_2 in KI, pulverizing the mixt., allowing it to stand overnight, filtering, and washing first with KI soln. and then with 0.01% H_2SO_4. B. Z. Kamich

Hydroxy- and aminoazonitro compounds. II. The use of α-naphtholazo-*p*-nitrobenzene as indicator for hydrogen ions in nonaqueous solvents. Leonid M. Kul'berg. *J. Gen. Chem.* (U. S. S. R.) **9**, 684–92(1939); cf. *C. A.* **33**, 3781[9]. As previously reported there exists an equil. in alk. solns. of α-naphtholazo-*p*-nitrobenzene (I) between the blue diquinoid form (II) and the yellow monoquinoid form (III). In the presence of nonaq. solvents miscible with water, the equil. is shifted so that the formation of II is favored. The tautomeric system is very sensitive toward H ions. This property as well as the characteristic color change at the transformation point of one form into the other renders I suitable to act as indicator in the microtitration of acids and bases. I is prepd. by diazotizing 5 g. nitroaniline, adding 5.3 g. 1-naphthol in alk. soln. to the diazo salt and, after 1 hr., acidifying the soln. with 20% HCl. The pptd. dye is filtered, washed with 1% HCl and with H_2O to remove Cl ions, and dried at room temp. to give an amorphous brick-red powder. II is obtained by boiling 3 g. I with 50 ml. 20% aq. soda soln. and 50 ml. EtOH until the compd. is completely dissolved. The amt. of EtOH is kept const. by adding new portions of EtOH. The soln. is filtered, the filtrate evapd., the residue is extd. with 96% alc. until all of II is eliminated. The filtered alc. exts. are evapd. and again extd. with alc. The alc. is slowly evapd. whereby II is obtained as black residue. To obtain III, 2 g. I is dissolved in 100 ml. Et_2O and the solu. is shaken with H_2O contg. CO_2. The ethereal layer contg. III is evapd. whereby III is obtained as a yellow-red powder. In the titration expts., the best results are obtained when the reaction is carried out at 100°. Errors, up to 20%, are observed when the titration is carried out at lower temps., such as, for instance, 25°, for 75% alc. solns., and up to 43% for aq. solns. It is required that the amt of H_2O does not exceed 50% of the vol. of the soln. to be titrated. The amt. of indicator used should preferably be 0.05–0.15 ml. of a 0.183% alc. soln. / 5–10 ml. of the soln. to be titrated. The salt error is very small and may be neglected when I is used as indicator. Gertrude Berend

Potentiometric titration of aluminum in silicate rocks. V. M. Tarayan. *Zavodskaya Lab.* **8**, 273–6(1939). Fuse 0.25–0.30 g. of the sample with Na_2CO_3, dissolve in HCl, ppt. the Ti, Al and Fe with NH_3, filter, wash with hot water and dissolve in 1 *N* HCl until acid to methyl orange. Sat. the soln. with NaCl, add an equal vol. alc., sat. with CO_2, add 3–4 drops of cold, satd. $FeSO_4$ soln. and titrate with 0.5 *N* NaF. The potentiometric results are as accurate as in gravimetric results. B. Z. K.

The determination of boron in small amounts and traces. O. Unverdorben and R. Fischer. *Bodenkunde u. Pflanzenernähr.* **13**, 177–91(1939). An improved procedure based upon that of Schulek and Vastagh (*C. A.* **25**, 3932) is described in detail. H_3BO_3 is isolated by distn. as Me borate and finally titrated in presence of mannitol with absolutely carbonate-free NaOH in the presence of phenolphthalein. Twenty-three references. S. J. S.

Determination of small amounts of cadmium in air. S. S. Genvits. *Zavodskaya Lab.* **8**, 424–7(1939).—It is shown that the insufficient sensitivity of colorimetric methods for detg. Cd in air is due to the colloid stabilizers which decrease the intensity of the coloration by 65–70%. To avoid this error the Cd was detd. colorimetrically with a Se photocell in a 20% Na_2S soln. without a stabilizer. The reagent is sensitive for 0.03–0.04 mgt Cd in 25 ml. soln. For the range 0.04–0.36 mg. Cd the error was from −1.4 to +9%. Small amts. of Cd up to 0.3 mg. can thus be detd. in the presence of 15–20 times as much Zn with an error up to 8.6%. B. Z. Kamich

Colorimetric determination of chromium in the form of trioxalatochromic acid. E. Ueberbacher and K. Th. Droscher. *Collegium* **1939**, 433–8.—By boiling solns. of chromic salts or chromates with oxalic acid, trioxalatochrome complexes are formed. About 10 mols. of oxalic acid per mol. of Cr is necessary. The color of the complex is intense blue-violet; it obeys the Lambert-Beer law, and the extinction curve has a max. at about 570. The concn. of Cr can be measured accurately with a "step photometer" or less accurately by prepg. standard solns. of known Cr concn. For Cr in leather take 2.75 g. leather, 5 g. oxalic acid and 100 cc. H_2O, boil 5 min., add kaolin, and bring to boil, cool, filter into a 100-cc. volumetric flask, and det. Cr colorimetrically. The basicity of Cr liquors can be detd. as follows: Boil 50 cc. of Cr salt soln. with 25 cc. *N* oxalic acid; dil. to 100 cc. and det. Cr in 20 cc. (*a* g.); titrate 5 cc. *N* oxalic acid with 0.1 *N* NaOH (*b* cc.); titrate 20 cc. trioxalato soln. with 0.1 *N* NaOH (*c* cc.). Basicity = $0.173\ (b - c)/a$. L. D. Clarke

Determination of small amounts of cobalt in ores, concentrates and tailings. Yu. Yu. Lur'e and E. M. Tal. *Zavodskaya Lab.* **8**, 383–8(1939). A comparative study of various methods indicates that the nitrite method followed by gravimetric detn. gives higher results and cannot be used. The most accurate method is the nitrite procedure followed by colorimetric detn. The method is, however, too long. The method of preliminary sepn. of Ni and Co by electrolysis without an outside current is not as accurate but it is satisfactory for routine analysis. Direct colorimetric test may give results sufficiently accurate for ordinary needs but it requires the addn. of enough pyrophosphate to bind the Fe as $NaFeP_2O_7$. This is the simplest and most rapid method. In case the ratio of Fe/Co is 4000 or more the nitrite-bromometric method is recommended. B. Z. Kamich

α-Nitro-β-naphthol as precipitant for cobalt and palladium. C. Mayr and W. Prodinger. *Z. anal. Chem.* **117**, 334(1939). In a previous paper (*C. A.* **29**, 698), M. claimed that α-nitro-β-naphthol was an excellent precipitant for Co and Pd. The reagent was found satisfactory by a no. of other chemists and the use of it mentioned in at least one standard text. Unfortunately, the method chosen for prepg. the reagent always results in the formation of some α-nitroso-β-naphthol which was recommended by Ilinski and v. Knorre (*Ber.* **18**, 699 (1885)) for detecting Co in the presence of Ni. The perfectly pure nitro compd. will not ppt. Co or Pd. W. T. H.

Rapid method for determining copper in low-grade ores and in flotation tailings. Yu. Yu. Lur'e and L. B. Ginzburg. *Zavodskaya Lab.* **8**, 271–3(1939).—Detn. of Cu in poor ores and flotation tailings by the pyridine-thiocyanate colorimetric method gave equally good results with and without the removal of the insol. residue. The formation of the complex should be carried out in citric acid and not in tartaric acid. B. Z. Kamich

Iodometric determination of copper in nitric acid solution. W. Orlik. *Z. anal. Chem.* **117**, 332–3(1939).—The procedure adopted by Hagen (*C. A.* **33**, 6748[2]) is very similar to that recommended by Orlik and Tietze (*C. A.* **24**, 2596). The use of $Pb(NO_3)_2$ to sharpen the starch-I_2 end point appears to be the only new feature of H.'s method. W. T. H.

Fermanganimetric titration of copper. Hisazi Kato and Tatuo Iwaba. *J. Chem. Soc. Japan* **60**, 703–4(1939). —By adding Fe powder to a soln. of $CuSO_4$, $FeSO_4$ is formed quantitatively and can be titrated with $KMnO_4$. The influence of other salts was studied. T. Katsurai

Rapid determination of copper in the presence of iron by the fluoroiodometric method. G. A. Taratorin. *Zavodskaya Lab.* **8**, 723–4(1939).—The method described is like that of Park (*C. A.* **25**, 660). B. Z. Kamich

Rapid method for determining small amounts of copper in metallic antimony of high purity. A. A. Vasil'ev and N. P. Vorob'eva. *Zavodskaya Lab.* **8**, 269–70(1939).—The method is based on the pyridine-thiocyanate colori-

metric method for detg. small quantities of Cu without previous sepn. of Sb or other elements. The Sb is kept in soln. with tartaric acid. B. Z. Kamich

Determination of copper and lead in metallic antimony and tin and in tin babbitt by electrolysis without an outside current. Yu. A. Chernikhov and E. V. Shtutser. *Zavodskaya Lab.* **8**, 801–6(1939).—Electrolysis was conducted in a modified Sand app. without an outside current. Anodes were Zn, Cd, Fe, Al, Pb and Cu while the cathode was Pt. Pb and Cu were sepd. out from HCl and HF solns. Cu was sepd. out with an Fe anode at room temp. in HCl soln., then the soln. was heated to 40–45° and the Pb was deposited with a Cd anode. The method can be used for detg. Pb and Cu in metallic Sb and Sn, and Sn babbitt, if the Sb and Sn is kept in solns. during electrolysis in the form of fluoride complexes. Eighteen references. B. Z. Kamich

Assay for gold and silver in black copper and in anode slimes. P. N. Maslenitskiĭ. *Zavodskaya Lab.* **8**, 665–8 (1939).—The results show that treatment of the slimes with acids preliminary to smelting results in loss of Au and is not recommended. B. Z. Kamich

Determination of iron, aluminum and magnesium with the aid of 8-hydroxyquinoline. H. Navez. *Ing. chim.* **23**, 1–26(1939).—Current methods were studied. The detns. can be carried out accurately by a modified Berg method (*C. A.* **24**, 801). The titration method is the fastest but gives low results and is unpleasant owing to the use of the CS_2. But the gravimetric method is so long that N. prefers the titration. Thirty-nine references. Ann Nicholson Hird

Colorimetric determination of iron in aluminum, alumina, hydrated alumina and aluminate liquors by means of sodium sulfide Liesolotte Roelen. *Z. anal. Chem.* **117**, 385–91(1939); cf. Ginsberg, *C. A.* **32**, 1601⁴.—The procedure is based upon the bluish green color produced in slightly basic solns. upon the addn. of a little Na_2S soln. Directions for carrying out the analysis with the Pulfrich photometer are given and the results are shown to correspond almost exactly with values obtained in titrating very dil. Fe solns. with $TiCl_3$. W. T. H.

Determination of ferrous iron in vivianites. V. A. Kazarinova-Okunin and N. A. Nikitina. *Zavodskaya Lab.* **8**, 498–9(1939).—Treat a 1–2 g. sample of vivianite with 100–200 ml. 5% HCl, place 10–20 ml. of the clear soln. in a cylinder equipped with a buret, capillary funnel, and a Bunsen valve, add 5–10 ml. of 10% HCl, a few drops of 1% methylene blue soln. and 5 g. $KHCO_3$. Expel air with CO_2, add 100 ml. of a soln. contg. 5 g. NH_4F and 1 g. $K_2C_2O_4$ through the funnel. Oxidize the Fe^{++} with 0.1 *N* I_2 soln. in the presence of starch. B. Z. Kamich

Determination of ferrous and ferric iron in sponge iron. N. I. Stognii. *Zavodskaya Lab.* **8**, 394–5(1939).—The Wilner-Merck method for detg. FeO and Fe_2O_3 was tested with sponge Fe and the results show that it is impossible to det. Fe_2O_3 in the presence of metallic Hg. By removing the metallic Hg and the basic salts from the Fe oxides before their soln. in HCl accurate results were obtained. The Hg is removed by sublimation. The procedure is as follows: Treat 0.5 g. of the sample with $HgCl_2$ under CO_2. Collect the Fe oxides and the metallic Hg on asbestos in a Gooch filter, wash successively with 5% NH_4 tartrate, water, alc., ether and dry in a stream of N_2 at 150° for 1 hr. Heat the ppt. in a stream of Cl_2 at 200–220° for 1 hr. Then dissolve the Fe oxides in HCl in a stream of CO_2, cool, filter and titrate the FeO in the filtrate with dichromate or permanganate. Fe_2O_3 is best detd. by difference. A large C content (over 5%) in the sponge Fe affects the detns. especially in the presence of surface-active C. B. Z. Kamich

Determination of lead in air by means of dithizone. V. M. Prikhnya. *Zavodskaya Lab.* **8**, 283–6(1939).—The detn. of Pb in air by means of dithizone was carried out with modified Palmer tubes containing HNO_3 as an absorbing agent. The set-up consisted of 2 tubes in parallel and one control tube. At an air speed of 10 l./min. the control tube was found to contain no Pb. B. Z. Kamich

Rapid potentiometric method of determining manganese in ores A. M. Avrunina and A. M. Zan'ko. *Zavodska. Lab.* **8**, 659–63(1939); cf. *C. A.* **33**, 4902⁶.—The methods of Lang (*C. A.* **29**, 7217⁵) and Müller for detg. Mn were checked with pure salts, Mn ores, Fe-Mn and spiegel. The former method gave accurate and reproducible results when HPO_3 was used to form the metaphosphate complex. The Muller method (*C. A.* **18**, 1628) also gave good results in the presence of 0.2–0.7 ml. of 0.4% OsO_4 soln. as a catalyst. B. Z. Kamich

Colorimetric determination of mercury in air by means of dithizone N. S. Kuzyatina. *Zavodskaya Lab.* **8**, 174–7 (1939).—The air to be tested is passed through 2 absorption tubes contg. 5 ml. of 0.1 *N* $KMnO_4$ and 5 ml. of 10% H_2SO_4 at the rate of 60–80 l. per hr. After the absorption, an aliquot part of the $KMnO_4$ soln. is taken, the permanganate is reduced to Mn^{++} by the addn. of a slight excess of $H_2C_2O_4$ at room temp. and the Hg^{++} content of the soln. is detd. by shaking with 0.05–0.1-ml. portions of a soln. of 1–2 mg. dithizone in 100 ml. of $CHCl_3$ and comparing the resulting color with that of standards in a colorimeter. Details are given. B. Z. Kamich

Photoelectric method of determining molybdenum in steel A. L. Davydov and V. F. Mal'tsev. *Zavodskaya Lab* **8**, 264–9(1939).—The method is based on the detn. of the complex formed from Mo and KCNS in a photoelec. colorimeter. Dissolve 0.5 g. steel in 10 ml. mixt. (prepd. from 225 ml. H_2SO_4 + 350 ml. HNO_3 + 750 ml. water), heat to expel oxides of N_2, and if carbides remain, add 1–2 ml. of 10% $(NH_4)_2S_2O_8$. If salts sep. out during the soln. of the steel, add 10–20 ml. mixt. (prepd. from 450 ml. H_2SO_4 + 100 ml. HCl + 1450 ml. water) and boil. After the persulfate is destroyed, cool, dil. to 100 ml. with water, and shake. Take 10 ml. of the soln., add 35 ml. of the H_2SO_4 and HNO_3 mixt., 40–45 ml. distd. water, shake, add 3 ml. 50% KCNS soln., 5 ml. of 10% $SnCl_2$ in HCl, dil. to 100 ml. and shake. The soln. is tested in the colorimeter 15 min. after the addn. of the $SnCl_2$. The concn. of Mo is detd. from a calibration chart or from tables previously prepd. An excess of KCNS does not affect the intensity of coloration. The reaction is not affected by the temp. at concns. of 2–3 *N* acidity. The analysis requires 40–45 min. and max. error is 4%. B. Z. Kamich

Vanadometric determination of molybdenum and phosphorus. V. V. Stepin. *Zavodskaya Lab.* **8**, 799–800(1939). —In this method the Mo is converted to Mo^{V} by Hg in a soln. which is 3 *N* in HCl. The soln. is filtered, H_2SO_4 (1:1) is added to make the soln. 7 *N* in H_2SO_4, then 2 ml. of 0.001 *M* phenylanthranilic acid added and the soln. is titrated with NH_4 vanadate to a permanent pink-violet coloration. In the detn. of P the steel sample is dissolved and after oxidation with $KMnO_4$ the P is pptd. as NH_4 phosphomolybdate, dissolved in NH_3, acidified with HCl, reduced with Hg, and titrated with NH_4 vanadate. The method is suitable for detg. small amts. of Mo and P in cast irons, steel., alloys and other materials. B. Z. Kamich

Rapid determination of nickel in steels and cast irons. I. M. Koreuman and G. D. Voronov. *Zavodskaya Lab.* **8**, 664–5(1939).—Dissolve a 0.2–1-g. sample in HNO_3, boil, cool, dil. to 200 ml. and filter. Add 5–25 ml. of 25% Rochelle salt, 5 ml. satd. Br water, 2 ml. of 25% NH_3 and 3 ml. of 1% alc. soln. of dimethylglyoxime to 5–25-ml. portions of the test and standard solns., and compare in a colorimeter after 5 min. B. Z. Kamich

Determination of zinc in sodium zinc uranyl acetate. V. B. Lewin and L. P. Tsentseva. *Trudy Ural. Ind. Inst. im. Kirova* **1938**, No. 5, 68–76; *Khim. Referat. Zhur.* **2**, No. 1, 66(1939).—An attempt to det. Zn as $NaZn(UO_2)_3(AcO)_9.6H_2O$ proved unsuccessful. All Zn was pptd. but the compn. of the ppt. did not correspond exactly to the above formula. It may be convenient, however, to isolate the Zn as the triple acetate and then dissolve the ppt. in dil. HCl and titrate the Zn with $K_4Fe(CN)_6$. It is claimed that the sepn. of Zn as triple acetate can take place in the presence of Ca, Sr, Ba, Fe, Mn, Ni, Cd, Cu, Hg, NH_4, K and Li. W. R. Henn

The electrolytic determination of zinc. Jan. Šebor.

hem. Lasty **33**, 304–5(1939)(French summary).—An attempt was made to det. Zn electrolytically with a current of 1–2 amps. in an electrolyte contg. 3 g. NH_4 citrate, 8 g. KOAc and 3–5 ml. of 10% AcOH, contained in a Ni vessel. During the electrolysis the soln. was stirred and the temp. maintained at 70–80°. The results obtained were about 4% low. The Ni vessel was badly corroded and appreciable quantities of black NiS were formed. Frank Mareshe 1

Determination of halides with ceric sulfate and starch indicator John F. Matejczyk. *Chemist Analyst* **28**, 54–5 (1939). - Add a measured vol. of 0.1 *N* $AgNO_3$ to ppt. the halide in the presence of dil. HNO_3. Filter, wash the ppt and to the filtrate add 5 ml. of 18 *N* H_2SO_4, 3 ml. of 0.5% starch paste and 15 drops of 0.1 *N* $Ce(SO_4)_2$ soln. Titrate the soln. with standard KI soln. until a permanent blue color is obtained. The iodide first serves to ppt. excess Ag and as soon as an excess of KI has been added, it is oxidized to I_2 by the ceric soln. and the end point is shown by a permanent color change. The results in 8 cited analyses of samples contg. 34–76% Cl were all within 0.5% of the wt. of sample taken. Three results were good. W. T. H. 2

Determination of small quantities of free chlorine in phosgene. Hans Martin, W. Oettinger and W. Kuhn. *Z. anal. Chem.* **117**, 305–17(1939).—The method is based upon the fact that $CoCl_2$ does not react with HgI_2 cmp. whereas Cl_2 reacts to liberate I_2. The loss in wt. due to the conversion of HgI_2 into $HgCl_2$ suffices to det. as little as 1 mg. Cl_2 in 10 g. of $CoCl_2$. It would perhaps be better to titrate the liberated I_2 with $Na_2S_2O_3$ but under the conditions studied free I_2 was present at the start. The exptl. work in connection with the prepn. and manipulation of definite known quantities of Cl_2 and the testing of the method is described. W. T. H. 3

Volumetric determination of fluorine by the Greeff method. Ya. P. Berkman and S. Ya. Bystrutskaya. *Zavodskaya Lab.* **8**, 725–6(1939).—In detg. F by the Greeff method (formation of Na_3FeF_6)(*C. A.* **7**, 3939) the optimum $FeCl_3$ concn. was found to be 0.4 *N*. The soln. should be neutralized exactly. In the presence of 1–2% sulfate the detns. are not affected, but higher sulfate concns. cause lower values. B. Z. Kamich 4

The determination of nitrogen in plant materials containing nitrates. E. Rauterberg and E. Knippenberg. *Bodenkunde u. Pflanzenernahr.* **13**, 194–8(1939); cf. *C. A.* **32**, 9326[3]. Expts. are described, with the conclusion that total N in plant materials contg. up to 3.5% nitrate N in dry matter can be detd. accurately. Nitrate is detd. in a sep. sample by the 2,4-xylenol colorimetric method. Org. N (including NH_3) is detd. by digesting a sample equiv. to 2 g. dry matter with 70 ml. H_2O in a 100-ml. Erlenmeyer flask 0.5 hr. on a boiling water bath, cooling and adding 25 ml. 5% AcOH. The mixt. is allowed to stand, filtered the next day and the residue washed a few times with 1% AcOH. The filtrate contg. the nonprotein N is evapd. to dryness and taken up with 5–10 ml. H_2O. About 5 g. powd. $FeCl_2$ is added, then 20 ml. concd. HCl, and the contents of the flask are digested on the boiling water bath for 1 hr. with frequent shaking, to decomp. all nitrate. Spattered solids are washed down and the soln. is evapd. to ½ vol. over a free flame, then transferred to a Kjeldahl flask with the filter and residue for the detn. of total N exclusive of nitrate, boiling off most of the H_2O before adding H_2SO_4, K_2SO_4 and Se catalyst for the digestion. The sum of the 2 detns. is the total N. Six references C. J. Schollenberger 5

The determination of oxygen in air. M. Kauttamaa. *Suomen Kemistilehti* **12A**, 108–9(1939). A satisfactory lab. or lecture expt. for the detn. of O_2 in air is performed by placing a 1-l. bottle with the bottom removed in water in a dish. Suction at the top of the bottle causes the rise of H_2O in the bottle by the removal of air. A triangle of Cu wire, 9 cm. on a side, is placed in the dish as a support for a wire 7 cm. long which holds a 4-cm. ring of Al sheet. Into this ring is placed a porcelain cup contg. burning red P. The bottle is placed over the triangle and the stopper fitted tight. The rise in H_2O is read from a previously prepd. scale on the side of the bottle. S. A. Kaijala 6

Determination of free carbon in carborundum. A. I. Miklashevskii. *Zavodskaya Lab.* **8**, 395–9(1939).—It is shown that the detn. of free C in carborundum by calcg. the wt. loss after ignition at 750–800° gives only approx. results because during the combustion of the C partial oxidation of SiC to SiO_2 occurs. At 800° the graphite burns completely and at 950°, 1000° and 1100° there is oxidation of SiC. It is proposed to det. graphically the free C in SiC and in carbide materials contg. up to 15–20% free C. The method is based on the difference in oxidation velocity between powd. graphite and SiC in a stream of O_2 at high temp. (950°) and involves the absorption of CO_2 gas. By heating for an extended length of time (3–4 hrs.) the oxidation velocity of the carbide drops. This is apparently due to the formation of SiO_2 which decreases the active surface for oxidation. The values for C as obtained by this method were higher than by combustion in a muffle. B. Z. Kamich 7

Determination of carbon and sulfur in carbonaceous pyrites. V. G. Timoshev and A. T. Shoshin. *Zavodskaya Lab.* **8**, 796–9(1939).—Gases formed in the combustion of a 0.25 g. sample were passed through 2 absorbers; the SO_2 was absorbed in 1.5% H_2O_2 in the first absorber and the CO_2 in a second absorber contg. 50 ml. 0.8333 *N* KOH. The H_2SO_4 formed in the first absorber was titrated with 0.3125 *N* KOH or NaOH. BaC_2O_4 was added to the second absorber and the excess KOH titrated with 0.8333 *N* HOAc. The app., procedures and calcns. are given in detail. B. Z. Kamich 8

Hydrolysis of the systems beryllium, aluminum, iron, sodium and potassium. G. Cottin. *Ing. chim.* **23**, 39–61 (1939).—The pptn. of Be, Al and Fe by NaOH, NH_4OH and KOH was studied. For pptg. Be from pure salts, C. prefers NaOH. Complete pptn. of $Be(OH)_2$ requires a min. pH of 7.2, with a mol. ratio: 1 BeO–10 alkali. Between pH 6.8 and 7.2 Al is pptd. quantitatively and is transformed into the aluminate at pH 9.75. As long as the pH is above 9.75 a quant. sepn. of the 2 elements Al and Be is obtained. The optimum mol. ratio is: 1 salt–6 alkali. The direct sepn. of Fe at pH 5 is not advisable. Twenty references. Ann Nicholson Hird 9

Influence of methanol upon the chloride titration with eosin as indicator. Walter V. Burg. *Chemist Analyst* **28**, 52–3(1939). - The ionization const. of eosin is sufficiently great to permit its application as indicator in the argentimetric titration of halogen at a pH somewhat lower than 4 but the adsorption of eosin by the AgCl ppt. is so great in comparison with the adsorption of Cl^- that a distinct color change takes place before the equivalence point is reached, as Fajans has pointed out. Although this would seem to prohibit the use of eosin as indicator for such titrations, it has been found that MeOH added as diluent (50 ml. added to 25 ml. of soln.) modifies the color change so that accurate results can be obtained in titrating 40–80 mg. of Cl^-. The av. error was less than 0.3%. W. T. H. 10

Volumetric determination of chlorate and bromate. C. Mahr and Hertha Ohle. *Z. anal. Chem.* **117**, 389–91 (1939); cf. *C. A.* **33**, 7238[1]. - The oxidation of $CS(NH_2)_2$ to $[NH_2(NH^+)CS]_2$ has been used for detg. the former and for titrating chromate or detg. MnO_2, PbO_2 and percompds. The oxidant is allowed to act upon an excess of $CS(NH_2)_2$ and the excess is measured by titration with $KBrO_3$-KBr soln. in the presence of KI. A similar procedure applies to the titration of chlorate or bromate and $KMnO_4$ can be used just as well as $KBrO_3$ for titrating the excess thiocarbamide. To det. ClO_3^-, mix 20 ml. of 18 *N* H_2SO_4, 5 ml. of 1% KI soln. and a carefully measured vol. of 0.1 *N* thiocarbamide. While rotating the contents of the vessel, add the chlorate soln., heat at 70° for 10–15 min., cool to 35°, add starch indicator soln., dil. to about 80 ml. and titrate with $KBrO_3$-KBr soln. or with $KMnO_4$. To det. BrO_3^-, start with the same mixt. and add the bromate soln. very slowly, almost dropwise. Heating on the water bath is unnecessary but the soln. should be heated to 35° before titrating. The results obtained were all within 0.03 ml. of 0.1 *N* soln. W. T. H. 11

The identification of chromate and permanganate in

mixtures. Luis Rossi and Carlos Vega. *Semana méd.* 1939, II, 628–30.—Sat. the soln. at pH over 3 with H_2S to form Cr^{+++} and Mn^{++}. Add filter paper pulp and filter off S. Add NaOH + H_2O_2 to form MnO_2 and CrO_4^{--}. Filter, test the filtrate for CrO_4^{--} with H_2O_2 and Et_2O. Dissolve the MnO_2 ppt. in hot $H_2C_2O_4$ and make one of the usual tests for Mn^{++}. A. E. Meyer

Critical study of methods for the analysis of hyposulfite preparations. H. Zocher and Hj. Saechtling. *Z. anal. Chem.* 117, 392–400(1939).— The analysis of hyposulfite preps. is complicated by the instability of $H_2S_2O_4$ itself. Thiosulfate and sulfite or bisulfite are formed from it. Wollak (*C. A.* 24, 2400) described a method for the analysis of a mixt. of thiosulfate, sulfite and hyposulfite which depends (1) upon the detn. of the total I_2 required to form tetrathionate, sulfate and bisulfate, (2) a similar titration after the addn. of HCHO which makes the sulfite unattackable and (3) the detn. of thiosulfate by a complicated method which consists of oxidation of $S_2O_3^{--}$ to $S_4O_6^{--}$ by means of excess I_2, treatment with SO_2 to remove excess I_2 and to convert $S_4O_6^{--} + S_2O_3^{--}$, treatment with HCHO to react with excess SO_3^{--} and iodometric titration of the newly formed $S_2O_3^{--}$. Test analyses showed that the first 2 procedures could be made to give consistent results but the third procedure is unreliable. For the detn. of $S_2O_4^{--}$, Seyewitz and Bloch (*C. A.* 2, 2229) recommended measuring its reducing effect upon $Ag(NH_3)_2^+$ whereby Ag and SO_4^{--} are formed and the Ag ppt. can be weighed or dissolved and titrated with thiocyanate. For practical purposes, it is best to disregard the thiosulfate content of hyposulfite preps. Usually very little is present. It is recommended to base the analysis upon the total I_2 consumption, the titration with I_2 after treatment with HCHO and the reduction of $Ag(NH_3)_2^+$ to Ag. Considerable data are given concerning numerous test analyses and the best conditions for carrying out the analysis. W. T. H.

Determination of caustic lime in commercial hydrated lime. Andrew Bender. *Chemist Analyst* 28, 56(1939).— Take 1.351 g. of pure Iceland spar and ignite to CaO. Cool. Dissolve the CaO and, separately, 1 g. of the com. sample in exactly 200 ml. of water to which 20 g. of sucrose has been added. Shake 1 hr. and titrate with 0.15–0.2 *N* acid to a phenolphthalein end point. The ratio of the vols. used for the 2 titrations is the ratio of CaO in the 2 samples. The acid does not have to be standardized. W. T. H.

Amalgam method for analyzing mercuric chloride. V. D. Ponomarev and D. S. Kolotov. *Zavodskaya Lab.* 8, 372–3(1939).— Dissolve the $HgCl_2$ in 25 ml. concd. H_2SO_4 and one l. water, dil. to make the acidity 0.1 *N*, shake an aliquot portion with 3% Zn amalgam in a closed test tube until the Hg is reduced (test with H_2S), and titrate the Cl in a 25-ml. portion with 0.1 *N* $AgNO_3$ by the Volhard method. The results are accurate. B. Z. K.

Determination of free alkali in potassium chromate reagent. L. E. Sabinina and A. A. Fabalova. *Zavodskaya Lab.* 8, 413–16(1939).— It is shown that the detn. of free alkali in K_2CrO_4 reagent by titrating with acid in presence of phenolphthalein gives inaccurate results. Instead the free alkali can be detd. by potentiometric titration with acid and a PbO_2 electrode. The possible error in this method is 0.001–0.002% (OH^-). B. Z. K.

Estimation of carbon disulfide. Angelo Castiglioni. *Ann. chim. applicata* 29, 196–8(1939); cf. *C. A.* 33, 2067⁶.— CS_2 has been shown to form a ppt. with piperazine, of the compn. $C_1H_{10}N_2CS_2$. The reaction is quant. only in the presence of a large excess of piperazine. The reaction takes place best with 95% EtOH as solvent. The ppt. is dried at 105°. Detns. are within 0.1–0.2%. For gaseous CS_2, the gas is bubbled through a concd. alc. soln. of piperazine. L. W. Contieri

Automatic detection and estimation of dangerous concentrations of ammonia and sulfur dioxide in air. B. A. Zalissev. *Zavodskaya Lab.* 8, 679–88(1939).—Various expts. are described for detecting and automatically estg. dangerous amts. of NH_3 and SO_2 in air. A tentative method was developed in which the air and the absorbing liquid are passed through a spiral coil and then through a gas separator from which the liquid is sepd. and its changing pH measured with an automatic photoelec. colorimeter equipped with optical or sound-signal devices. The absorbing liquids were 0.0005 *N* H_2SO_4 and 0.0005 *N* H_2O_2 for NH_3 and SO_2, resp., with 4 mg./l. of bromophenol blue indicator for both. The sensitivity of the app. can be varied by changing the ratio of air velocity to the velocity of the absorbing liquid. Diagrams of the app. are included. B. Z. Kamich

Determination of sulfur dioxide in the presence of nitrogen. G. V. Rabovskiĭ, A. C. Derenkovskaya and L. L. Linde. *Zavodskaya Lab.* 8, 372–8(1939).—A comparative evaluation of various methods for detg. SO_2 in mixts. contg. oxides of N indicates that the methods of Raschig (*C. A.* 23, 2787), of Shults, of Kangun (*C. A.* 28, 5365⁴), and of Ugnyachev (*C. A.* 32, 6176⁵) do not give reliable results. About 1–2 l. of gas is blown at a rate of 3–4 drops per sec., through a Drexel tube contg. 100 ml. of 3% H_2O_2. One-fourth of the soln. is neutralized with 0.1 *N* NaOH to methyl red, heated to boiling, and 0.5 *N* $BaCl_2$ is added dropwise until it is equal to the ml. of 0.1 *N* NaOH added. The soln. is cooled to room temp., 10 ml. alc. is added, then 0.5 ml. of 0.5% alc. soln. of rosolic acid, and the soln. is titrated with 0.05 *N* K_2CrO_4 to disappearance of red coloration. The method takes 20–25 min. and is suitable for use in H_2SO_4 plants. B. Z. Kamich

Method for determining moisture in salts of high electric conductivity. Kh. I. Vorakso, L. I. Grudkova and K. P. Mishchenko. *Zavodskaya Lab.* 8, 837–42(1939).— A method is described for controlling moisture in NaCl, KCl and NH_4NO_3 by measuring the changes in dielec. const. by the method of resonance using a condenser in which the salt to be investigated occupies only a part of the field. Both ultra-short and short waves were used but the latter does not give accurate and sufficiently differentiated results. The moisture is measured with an accuracy of 0.3%. B. Z. Kamich

Spectral analysis of minerals and solutions. A. K. Rusanov and K. N. Vasil'ev. *Zavodskaya Lab.* 8, 832–7(1939).—In the spectral analysis of minerals the powd. materials were "blown" onto an acetylene-oxygen flame and from the intensity of the lines it was possible to est. concn. of Cs and Rb in 0.001, 0.01, 0.1 and 1%. For more accurate results the chloride solns. of Cs, Rb and K contg. Mn as a secondary element were used. Accuracies were ±2.5% for Rb, ±3.0% for K, and ±2.2% for Mn. The min. amt. of soln. necessary is 2 ml. B. Z. Kamich

Geological measurement of time by the analysis of monazite. Edith Thoupa. *Mikrochemie* 27, 165–75(1939).— In monazite the ratio of the Pb to the Th content is important for the measurement of geol. time. Microchem. methods of analysis are recommended because of the economy with respect to both time and material. In the work here described, the Pb was detd. as $PbSO_4$. For the Th detn. treatment with NH_4NO_3 and H_2O_2 served to sep. Th from the rare earths. The ppt. was dissolved in HNO_3, the H_2O_2 removed by evapn., the Th was pptd. by addn. of NH_3 and the ppt. ignited to oxide. UO_2^{++} was also detd. with the aid of oxine. The procedure, which is described, was tested by means of a synthetic monazite contg. known quantities of the various constituents. The results obtained were excellent. W. T. H.

Analysis of zircon sand. M. Axt. *Ing. chim.* 23, 142–5(1939).— Fusion with NaOH disintegrates a ½-g. sample of the sand in 5 min. at a temp. of 600°. Evapn. with H_2SO_4 to white fumes gives perfect results for SiO_2. The $(NH_4)_2AsO_4$ method for detg. ZrO_2 is very exact. This method can be used to analyze other minerals of Zr such as baddeleyite or zirkite. Ann Nicholson Hird

The sensitivity of the picrate paper test (Guignard test) for hydrocyanic acid. Douw G. Steyn. *J. S. African Vet. Med. Assoc.* 10, 65–8(1939).—The limit of the picrate paper test lies at about 0.00052 mg. HCN in 5 cc. soln. The test is more sensitive at high temps. (55–60° for 1.5 hrs. and 37–38° for a further 16 hrs.) than at low temps. (30° for 1.5 hrs. and 15–20° for a further 16 hrs.).

The picrate paper test yields very satisfactory results with plants, but gives unreliable results on animal and human organs and other materials which are likely to contain reducing substances. In such cases the test in which $Fe(CNS)_3$ is formed is the most reliable and most sensitive for HCN. K. D. Jacob

Argentometric titration of selenious acid. Raluca Ripan-Tilici. *Z. anal. Chem.* **117**, 326–30(1939); cf. *C. A.* **32**, 6753⁹.—From 25 to 50 ml. of 0.1 *M* Na_2SeO_3 soln. can be titrated accurately at pH 9.6 with $AgNO_3$ in the presence of fluorescein as adsorption indicator. The soln. should be dild. with 10 vols. of water before titrating. At the start the ppt. of Ag_2SeO_3 assumes a yellowish pink color, but turns fiery red as soon as the equivalence point is reached. Under similar conditions the titration succeeds also with diphenylcarbazone as indicator although some practice is required in detg. the end point. Another possibility consists in adding a measured excess of $AgNO_3$ and detg. the excess Ag gravimetrically, volumetrically or electrometrically. W. T. H.

Volumetric determination of sulfuric acid combined with alkali metal. Albert Krüger. *Z. anal. Chem.* **117**, 333 (1939).—The reaction $Na_2SO_4 + BaCO_3 = BaSO_4 + Na_2CO_3$ can be made to go to completion by treating the cold soln. of Na_2SO_4 with $BaCO_3$ in suspension while introducing CO_2. The ppt. of $BaSO_4$ together with excess $BaCO_3$ can be filtered off and the filtrate titrated with HCl to a methyl orange end point. Details concerning the accuracy and reliability of the procedure will probably be published soon. W. T. H.

New data for the spot-plate detection of certain ions. E. A. Kocsis. *Mikrochemie* **27**, 180–4(1939).—A 0.2% aq. soln. of benzopurpurin 4 B in contact with a drop of soln. contg. Ag^+ gives a brown ring outside the inner red spot which appears like the color of benzopurpurin itself. The test is given with 0.03 mg. of Ag. With 0.04 mg. Hg_2^{++} benzopurpurin gives a bright reddish violet test and with 0.015 mg. Hg^{++} a bluish gray ring. 0.025 mg. Hg^{++} gives a bright reddish brown spot with benzopurpurin and 0.02 mg. Hg^{++} gives a yellow spot with bromophenol blue. With these reagents it is easy to distinguish between Hg_2^{++} and Hg^{++}. Bromophenol blue gives a violet-red ring with Pb^{++} and 0.025 mg. of Pb will give the test. As little as 0.035 mg. of U can be detected by the light-brown ring which UO_2^{++} gives with benzopurpurin. This reagent also serves to detect 0.005 mg. of Al by the reddish brown spot. The morin test for Al will detect as little as 0.001 γ of Al if the reagent, a 0.2% soln. in EtOH, is added to 1 ml. of the soln. to be tested and the mixt. is exaind. under ultraviolet light. W. T. H.

Rapid method for determining magnesium, calcium and barium ions. N. K. Senyuta. *Zavodskaya Lab.* **8**, 721–3(1939).—In this method Ba, Mg or Ca is pptd. by means of a measured vol. of standard Na_2CO_3, NaOH or $Na_2C_2O_4$ soln., resp. The ppt. is removed and the excess Na_2CO_3 or NaOH titrated with standard acid in the case of Ba or Mg and with $KMnO_4$ in the presence of hot, dil. acid in the case of Ca. An immiscible liquid such as $CHCl_3$ or CCl_4 was used for removing the ppts. from the conical tubes in which pptn. took place. The results were within 0.8% of the truth. B. Z. Kamich

Oxalate method for determining sulfate ion. I. G. Lakomkin. *Zavodskaya Lab.* **8**, 416–21(1939).—To det. 50–100 mg. SO_3 in 100 ml. of soln., first remove alk. earths by treatment with Na_2CO_3. Make the soln. neutral by adding HCl and add BaC_2O_4 which forms less sol. $BaSO_4$ and an equiv. wt. of $C_2O_4^{--}$ goes into soln. Filter, make acid and titrate the $C_2O_4^{--}$ with $KMnO_4$ under the usual conditions. B. Z. Kamich

Current microchemical literature. Edith Nadler. *Mikrochemie* **27**, 231–9(1939); cf. *C. A.* **33**, 5771⁴.—The review covers May 5 to June 20, 1939. W. T. H.

Application of salts of complex cations to the microscopic detection of anions. VIII. 1,2-Chloroaquotetramminocobaltic chloride. L. K. Yanowski and W. A. Hynes. *Mikrochemie* **27**, 161–4(1939); cf. *C. A.* **33**, 4548³.—A satd. soln. of $[Co(NH_3)_4(H_2O)Cl]Cl_2$ gives characteristic crystals by reacting with PO_4^{---} or with $P_2O_7^{----}$ ions. With PO_4^{---} the shape of the reaction product varies with the pH of the soln. from which it is formed. W. T. H.

The application of salts of complex cations to the microscopic detection of anions. IX. W. A. Hynes and L. K. Yanowski. *Mikrochemie* **27**, 335–48(1939)(in English).—Roseocobaltic chloride gives characteristic crystals with oxalates, sulfosalicylic acid, dithionates, ferricyanides, ferrocyanides, fluosilicates and phosphomolybdates. Of these only the first 4 mentioned are to be recommended for the identification of the ions in question. W. T. H.

Microdeterminations with ordinary analytical balances. A. A. Benedetti-Pichler and R. A. Paulson. *Mikrochemie* **27**, 339–47(1939).—Five short-arm balances costing on the av. about $65 each, such as are used by students in the U. S. A., were tested. The oldest balance was purchased in 1924 and the newest in 1935. The predictions of a previous paper (*C. A.* **33**, 4083³) were put to a practical test with respect to the extent to which the ordinary balance could be used safely for small samples. The methods studied included the detn. of Na as sulfate in a sample of pure $Na_2C_2O_4$, the detn. of Al in a sample of alum, the detn. of Ca in a pure sample of $CaCO_3$ and the detn. of Mg in a sample of freshly crystd. $MgSO_4.6H_2O$. Samples weighing 5–18 mg. were taken. The largest deviation actually obtained amounted to about 1.0% of the actual content which is somewhat better than was to be expected. W. T. H.

A list of micromethods for the determination of calcium and phosphate. R. S. Manly. *Mikrochemie* **27**, 145–53 (1939).—The elements P and Ca are of such *biol. importance* that no less than 78 papers have appeared recently concerning the microchem. detn. of these elements. The purpose of this compilation is to provide a ready reference list for workers who anticipate carrying out routine work. The principle upon which each procedure is based, the necessary quantity of material, the necessary app. and reagents, as well as the precision and accuracy, are all stated. W. T. H.

Vanadometric microchemical determination of iron. V. V. Stepin. *Zavodskaya Lab.* **8**, 262–4(1939).—In this method the Fe^{++} in the soln. is titrated in 6 *N* H_2SO_4 with 0.01 or 0.0025 *N* NH_4 vanadate in the presence of phenylanthranilic acid indicator. Results of titration on samples of 0.5 g. and contg. as little as 0.04% Fe gave satisfactory results. The method is especially suitable for analyzing limestones, Mn ores and silicates. B. Z. Kamich

The microchemical, gasometric determination of nitrogen in organic compounds. H. Gysel. *Helv. Chim. Acta* **22**, 1085–95(1939).—The method was tested with 1.2–3.5-mg. samples of substance such as strychnine nitrate, barbital, semicarbazone and urea derivs. It is a modification of the Dumas method and makes use of 2 short furnaces of which the front one is movable. In spite of the small samples used and the relatively small vols. of N_2 measured, the results were remarkably accurate. W. T. H.

Microdetermination of sulfur in organic compounds. N. E. Gel'man. *Zavodskaya Lab.* **8**, 673–7(1939).—In a modified Meulen method (cf. *C. A.* **30**, 416⁶) a 3–5-mg. sample is heated in a Pt boat, the vapors of the org. compd. are passed with a stream of H_2 over a heated catalyst of rolled Pt gauze, the H_2S is absorbed in a buffered $ZnSO_4$ soln. and the S is detd. iodometrically. The combustion tube contg. the Pt boat and Pt catalyst is 55 cm. long, 8–9 mm. in diam. (inside), and is made of quartz. The glass absorption tube was bent at 45° with the vertical end connected to the combustion tube and the inclined arm shaped into a series of bulbs. Detns. of S on 8 org. compds. showed close agreement with the theoretical values. The procedure and app. are described in detail. B. Z. K.

Microchemical method for the potentiometric "formol" titration. A. Janke and E. Mikschik. *Mikrochemie* **27**, 176–9(1939).—Amino acids contain at one end of the mol. the basic NH_2 group and at the other end the acid CO_2H group. Just as NH_3 reacts with HCHO to form hexamethylenetetramine, so the NH_2 group loses its basic

properties by reacting with HCHO. The so-called "formol" titration consists in adding HCHO and then detg. the vol. of NaOH required to change the soln. from pH 7 to pH 9. An ingenious app. is shown in which the container also serves as glass electrode. By means of a magnet, the soln. is kept in motion during the titration and the end point is detd. electrometrically. W. T. H.

Chemical microscopy of some toxicologically important alkaloids. W. F. Whitmore and C. A. Wood. *Mikrochemie* **27**, 249-334(1939)(in English).—Many of the available confirmatory tests for alkaloids are not sufficiently reliable. In the work here described, the degree of specificity was detd. for every test and the alkaloids studied included β-eucaine, cocaine, procaine, stovaine, cinchonine, cinchonidine, quinine, quinidine, codeine, dionine, heroine, morphine, narcotine, papaverine, brucine, strychnine, caffeine, theobromine, atropine and nicotine. More than 40 reagents were applied systematically to every one of these alkaloids and by comparison of the results satisfactory specific tests were discovered. All cryst. properties were studied under the polarizing microscope. Birefringency was designated as weak or strong. The angle of extinction was detd. and the sign of elongation observed with the selenite plate. The term pos. elongation is used to indicate the fact that the slower component of light vibrates approx. parallel to the longer direction of the crystal and, conversely, neg. elongation is used to denote vibration of the faster component of light approx. parallel to the outstanding direction of form. Pleochroism was reported and in some cases prolate or silhouette angles were measured. Refractive indexes were not detd. β-Eucaine gave a no. of cryst. complex salts and in general the reagents gave similar ppts. with both β-eucaine and cocaine. Fortunately, since eucaine is used as cocaine substitute, the derivs. of cocaine differ in appearance and optical characteristics from those of eucaine. The bromoplatinate deriv. is best suited for the identification of β-eucaine, particularly in conjunction with the optical properties. Cupferron is a very specific reagent for β-eucaine as it was the only alkaloid studied which gave a cryst. deriv. With cocaine, the most characteristic, cryst. deriv. is the ppt. formed with $NaAgI_2$. No other alkaloid gave crystals with this reagent except brucine and strychnine but the crystals formed with these alkaloids are easily distinguishable from the cocaine ppt. Practically the same is true with respect to the double salt that cocaine forms with HgI_2. H_2PtCl_6 dissolved in 5% HBr is much more useful with cocaine than the usual HCl soln. of this reagent. Procaine yields many ppts. but most of them are not cryst. The most characteristic crystals were obtained with a soln. of Br_2 and KBr. The iodoauric and bromoauric acid salts are next in order of usefulness and the crystals obtained with $CdBr_2$ are of some interest. The test with β-naphthol was not given by any other alkaloid tested. With stovaine, most of the many ppts. would not crystallize. The complex with $AuBr_4^-$, especially when recrystd. from EtOH, is most useful for the identification of stovaine. The most characteristic test for cinchonine was obtained with H_2PtCl_6 in 20% HBr. The perchlorate crystals are also useful but not easy to obtain. K_2HgI_4 is a useful reagent for cinchonine because this reagent gives relatively few cryst. ppts. and only very little cinchonine is required to give the test. The main group of the Pt metals (Os, Ir and Pt) give characteristic tests with cinchonidine and the ppt. obtained with Na_2OsCl_4 is most convenient with respect to size, soly. and optical consts. The crystals obtained with Na_2SnI_4 are useful because few alkaloids react with this reagent. For quinidine, the most characteristic test was obtained with a crystal of K anthraquinone sulfonate added to the test drop and then heated. The crystals obtained were easy to identify. Quinine is characterized by its tendency to ppt. as sulfate from aq. solns. The ppt. formed with H_2PtCl_6 in 20% HBr added to a 1% soln. of quinine sulfate is a useful and unusual test form. With codeine, the best test was obtained with CdI_2 but K_2HgBr_4 is a useful reagent since relatively few alkaloids give ppts. with the neutral soln. of this reagent. With dionine, the most useful test is obtained with H_2PtCl_6 in 5% Br soln. or with Na_2PtF_6. The crystals are easy to obtain and are characteristic. For heroine, the most specific test is obtained with $CdCl_2$. The crystals produced with Na_2PtBr_6 are of value if the optical properties are studied and anthraquinone sulfonate is of some value as a reagent for heroine. Morphine is detected by means of Na_2SnI_4 although codeine and dionine give similar ppts. The test with K_2HgBr_4 is characteristic. Narcotine gives ppts. with many reagents but the test with borax is the most characteristic when the soly. and optical properties of the crystals are studied. The forms produced with $IrCl_4$ are characteristic but not as easily obtained as the ones with borax. Papaverine also gives many ppts. but the most specific test is with CdI_2 although the test with $TiCl_3$ is also specific. Brucine, like strychnine, forms many ppts. and it is difficult to pick out the best test. The formation of crystals with $BiCl_3$ is a test to be recommended and although strychnine gives a similar test the crystals are different in shape and in sign of elongation. $K_2Hg(SCN)_4$ and K xanthate give quite characteristic ppts. Strychnine gives more cryst. ppts. with the 40 reagents used than does any other alkaloid. HSbCl, K H phthalate, $KSbOC_4H_4O_6$ and NH_4VO_3 give ppts. only with strychnine and the SbO deriv. is the most reliable test for the identification of strychnine. The crystals are apparently isotropic which was not true of any of the other crystals studied in this investigation. Caffeine shows little tendency to form insol. ppts. with the various reagents. The most useful crystals were obtained with the alkaloid reagents contg. Br or I. The most specific test is given by Br_2 in NaBr; hexagonal crystals are obtained. The K_2PtI_6 and NaAuBr tests are good but less specific. Theobromine gives many cryst. ppts. but they are not very characteristic. The long needles obtained with Br_2 in NaBr are most specific and useful for distinguishing between caffeine and theobromine. The $KAuI_2$ and $NaAuBr_4$ tests are useful but less specific. Nicotine, like brucine, is characterized by its tendency to form complex metallo-thiocyanates. The Co compd. is most useful for identification purposes. With K_2HgBr_4 crystals were obtained which showed oblique extinction and this is the only case where such crystals were obtained with this reagent. Atropine gives few ppts. and the best reagent was Br_2 in NaBr. A summary of the action of 40 reagents upon all of the alkaloids is given and 138 photographic reproductions of the best tests are shown. W. T. H.

Influence of putrefaction on the detection of alkaloids in cadavers by the absorption spectrograph. Fritz Strieck. *Deut. Z. ges. gerichtl. Med.* **30**, 297-8(1939).—Putrefaction products do not make the identification of alkaloids by absorption spectrum analysis impossible, if the alkaloid is present in greater quantity than the contaminants. Quantitatively, absorption spectra can indicate upper limits only. The method can be used only as an aid to other analyses. Frances Krasnow

Determination of aromatic hydrocarbons by a new method. Aristid V. Grosse and Richard C. Wackher. *Ind. Eng. Chem., Anal. Ed.* **11**, 614-24(1939).—The method was developed for the rapid analysis of hydrocarbon mixts. boiling in the gasoline and naphtha range. It is based upon the detn. of the sp. dispersion of the hydrocarbon mixt. Tables show the dispersion and sp. dispersion of over 50 hydrocarbons. The effect of double bonds and the relation of sp. dispersion and unsatu. is discussed and analyses are given of mixts. contg. conjugated diolefins. The method is proposed for pure hydrocarbon mixts. which boil below 220° but the effects produced by the presence of O, S and halogen compds. are discussed. The percentage of aromatic compds. found by this dispersion method agrees in most cases fairly well with values obtained by H_2SO_4 although in one case the latter method gave a value 50% higher. W. T. H.

Determination of aromatic hydrocarbons in light kerosene by the method of aniline points. V. I. Artyukhin and Ts. L. Glanovskaya. *Zavodskaya Lab.* **8**, 728-30 (1939).—In detg. the aromatic content of light kerosene by the method of aniline points the following precautions should be observed to obtain accurate results: (1) only

freshly distd. aniline should be used, (2) the water bath should be cooled gradually, (3) after stirring the overheating should not be allowed to rise by more than 5-6°, and (4) the ratio of aniline to light kerosene should be carefully maintained at 1:1. B. Z. Kamich

Polarographic method for determining organic peroxides. A. A. Dobrinskaya and M. B. Neiman. *Zavodskaya Lab.* **8**, 280–3(1939).—Polarograms are given of various concns. of H_2O_2, CH_3OOH, diethyl peroxide, formaldehyde, acetaldehyde, and a 2% condensate obtained in cold flame oxidation of acetaldehyde. The results indicate that the polarographic method can be used for qual. and quant. analyses of peroxides, in studying oxidation of aldehydes, cracking gasolines, oils, pharmaceutical prepns., and primary and by-products of the synthetic rubber industry. Nineteen references. B. Z. Kamich

Determination of small amounts of mercury in organic compounds with potassium iodide. N. V. Koshkin. *Zavodskaya Lab.* **8**, 677–9(1939).—The Korenman method (*C. A.* **29**, 71⁶, 2471⁷) for detg. small amts. of Hg in org. compds. by titrating with KI was modified so as to approach the end point from a colorless soln. to a blue coloration. The end point was very sharp and in detns. of 0.2–2 mg. Hg in 1 ml. soln. the av. error did not exceed 3%. Equally good results are obtained by titrating with 0.001 *N* and 0.01 *N* KI but in the latter case the end point is sharper. B. Z. Kamich

Amyl alcohol for the estimation of the nitrogen distribution by Van Slyke's method. Masakazu Sato, Tamotu Hirano and Hirosi Kamati. *J. Agr. Chem. Soc. Japan* **15**, 791–4; *Bull. Agr. Chem. Soc. Japan* **15**, 124–5(1939)(in English).—The exptl. error in the content of basic amino N has often been observed. It is due to the presence of pyridine in com. amyl alc., which is used for the removal of phosphotungstic acid in Van Slyke's method (*C. A.* **5**, 509, 2856.) One part of com. amyl alc. should be washed 3 times with 2 parts of 5% HCl to remove pyridine. Y. Kihara

Determination of ethyl alcohol after preliminary purification of the alcohol vapors by adsorption. E. Schulek and P. Rozsa. *Z. anal. Chem.* **117**, 400–14(1939).—EtOH is often detd. by distn. and measuring the d. or the *n* of the distillate. Such a method is not satisfactory for the examn. of many pharmaceutical prepns. contg. other volatile constituents. The method here described, which was tested with synthetic mixts. and with various prepns. such as spirit of camphor, alc. soln. of salicylic acid, menthol or mustard, cologne water, brandy, wine, mouth washes, han tonic and various tinctures, is a purely chem. procedure. It depends upon the volatilization of 5–15 mg. of EtOH by the passage of considerable air at room temp. The air containing EtOH vapors is passed over a suitable quantity of dry, "amphoteric" activated C which serves to remove interfering vapors. The quantity of C required is detd. by testing its adsorption power toward antipyrine. A quantity sufficient to adsorb 12–15 mg. of antipyrine will not adsorb 5–20 mg. of EtOH. The vapors after the adsorption of impurities are passed into 25 ml. of 0.1 *N* $K_2Cr_2O_7$ soln. to which sufficient H_2SO_4 has been added to make the d. = 1.62. The dichromate oxidizes the EtOH to AcOH. Finally the excess dichromate is detd. iodometrically. A special app. is shown which is suitable for the analysis and various precautions are noted which are essential for carrying out the detn. which is shown to give excellent results. W. T. H.

Determination of the diethylamides of nicotinic and phthalic acids. K. A. Jacobsohn and F. Reitmers. *Z. anal. Chem.* **117**, 415–20(1939). —A common method for the analysis of amides consists in accomplishing hydrolysis by boiling with dil. acid or base followed by titration of the NH_3 formed. This procedure also gives good results with many substituted amides but with coramine (*N,N*-diethylnicotinamide) nicotinic acid and diethylamine are formed. The latter has a b. p. of 56° and is not easy to det. Recently various prepns. were placed on the market and the effective constituent is closely related to coramine. This includes phthalic acid-bis-diethyl amide(neospiran) which has recently come into use. For the detn. of coramine, take a quantity corresponding to about 0.4 g. of this substance, mix with 100 ml. of water and an equal vol. of concd. NaOH soln. in a 1. flask. Add a little pumice and connect with a Kjeldahl distn. flask. Place 25.00 ml. of 0.1 *N* HCl in the 250-ml. Erlenmeyer flask which serves as receiver. Heat the mixt. slowly to boiling and keep barely boiling for 20 min. without much distn. Then heat more strongly and distil off 100 ml. of liquid under good condensation. Then add 25 ml. more of water through a dropping funnel in the neck of the flask and distil until 125 ml. of total distillate has been collected. Titrate with 0.1 *N* borax or NaOH soln. to a methyl red end point. Good results were obtained with the substituted amide of phthalic acid. W. T. H.

The microscopy of the amino acids and their compounds. IV. Picrolonates. Rayburn Dunn, Kazuo Inoue and Paul L. Kirk. *Mikrochemie* **27**, 154–60(1939); cf. *C. A.* **31**, 4356⁹.—Alanine, arginine, aspartic acid, cysteine, cystine, dibromotyrosine, dichlorotyrosine, diiodotyrosine, glutamic acid, glycine, histidine, hydroxyproline, hydroxyvaline, isoleucine, isoserine, leucine, lysine methionine, norleucine, norvaline, phenylalanine, proline serine, tryptophan, tyrosine, valine and *dl*-α-amino-γ-valeric acid all yield cryst. picrolonates which can serve for identification. The predominant crystal habit is acicular and although direct examn. of the crystals under the microscope is not always sufficient for the characterization, it is possible in nearly every case to identify the amino acid by the refractive index. W. T. H.

Determination of furfural in furfural furfuryl alcohol solution. A. P. Dunlop and Floyd Trimble. *Ind. Eng. Chem. Anal. Ed.* **11**, 602–3(1939).—To 5 ml. of soln. in a glass-stoppered flask add 25 ml. approx. 0.1 *N* $NaHSO_3$ soln. Shake, allow to stand 15 min., add starch and titrate with 0.1 *N* I_2 soln. At the same time det. the I_2 consumption of the $NaHSO_3$ soln. under exactly the same conditions with respect to standing, etc. A nomograph for calg. the results is given. W. T. H.

Determination of pyridine in ammonia by means of bromine cyanide and benzidine. R. I. Alekseev. *Zavodskaya Lab.* **8**, 807–9(1939).—Pyridine in NH_3 is detd. colorimetrically by causing it to react with BrCN and benzidine and extg. the colored compd. with isoamyl alc. Before the colorimetric test the NH_3 should be neutralized exactly to *p*-nitrophenol as indicator. The presence of neutral salts has no harmful effect. The optimum pyridine quantity to be detd. colorimetrically is 0.003–0.05 mg. and at least 0.3 γ must be present. Twenty references. B. Z. Kamich

Determination of 8-hydroxyquinoline in the presence of thiosalicylic acid. Angelo Castiglioni. *Ann. chim. applicata* **29**, 315–16(1939). 8-Hydroxyquinoline is detd. by pptn. with silicotungstic acid; it gives a bulky yellow ppt. having the compn.: $12WO_3.SiO_2.4C_9H_7ON.4H_2O$. The silicotungstic acid (10% soln.) is added to an acidified (HCl) soln. of 8-hydroxyquinoline; any thiosalicylic acid present in soln. is not affected. The ppt. settles in 7–8 hrs. and is filtered, ignited, dried at 105° and weighed. As the conversion factor to 8-hydroxyquinoline is 4.903, a small amt. of the latter can be detd. with precision. A. W. Contieri

Nephelometric method for determining nicotine. K. B. Trifonova. *Zavodskaya Lab.* **8**, 731(1939).—Add 10 drops of 1% silicotungstic acid and 3–4 drops of 10% HCl to equal amts. of water in 2 beakers, then add 3 ml. of the test soln. to one beaker and to the other a standard nicotine soln. until an equal opalescence is obtained. The results are satisfactory. B. Z. Kamich

Characterization of acetylsalicylic acid preparations. Iodometric determination of salicylic acid. D. Kruger. *Z. anal. Chem.* **117**, 318–26(1939).—Although acetylsalicylic acid is an old pharmaceutical prepn. and considerable attention has been paid to the detn. of its purity, as is shown by over 30 references, it is a well-known fact that the prepn. is found on the market with very different phys. and medical properties. The difficulties in connection with its analysis are pointed out and, as a result of study, it is

recommended to det. the salicylic acid content by iodometric titration. To about 0.3 g. of sample, add 15 ml. of 0.5 *N* NaOH and allow to stand overnight or heat for some time on the water bath completely to hydrolyze the compd. into Na salicylate. Add 0.5 g. Na_2CO_3, 50 ml. of water and 20 ml. of 0.1 *N* I_2 soln. After 20–30 min. add 2 ml. of 3.5 *N* H_2SO_4 and titrate with $Na_2S_2O_3$. One mole salicylate absorbs 6 atoms of I. For the analysis of tablets it is best to recrystallize from CCl_4. In the analysis of 4 samples, the values 76.48, 76.66, 75.71 and 76.58% were obtained which, by comparison with the theoretical value of 76.67, showed that one sample was quite impure. It is thought that the method gives results within about 0.1% of the truth. W. T. H.

Detection of porphyrin and other organic substances in calcite and aragonite. H. Haberlandt. *Naturwissenschaften* **27**, 615–14(1939).—A pink calcite from Altenburg left a red residue upon treatment with HCl. The soly. of the red residue in EtOAl, other ales. and EtOH + AcOH, the absorption and fluorescence bands of the pin solns. and the bands of the mineral itself make it seem probable that porphyrin is present as a result of bacterial action. A red calcit found in Quincy, France, may also contain porphyrin. B. J. C. van der Hoeven

Mol. compds. of methyl α-naphthol ether and dinitro products [identification of dinitro compds.] (Burmistrov) 10. [Detn. of] Cb and Ta (Klinger) 6.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

ARTHUR M. BRANT

Notes on the use of methyl methacrylate "Lucite" in a geological laboratory. James V. Bell. *Econ. Geol.* **34**, 804–11(1939).—The material is especially useful for impregnating fragile or friable specimens, of which thin sections are desired. Detailed directions are given. Michael Fleischer

Disintegration of beryllium minerals. Robert Strauss. *Can. Chem. Process Inds.* **23**, 500–2(1939).—Raw Be minerals are disintegrated by: (1) the aid of F compds., (2) alkali, (3) Cl and (4) CO_2. Each method is outlined and the nos. of several American, French and German patents are appended. W. H. Boynton

Mineral syntheses by detonation of brisant explosives and pneumatolysis. Albert Michel-Lévy. *Bull. soc. géol. France* **9**, 105–10(1939); cf. *C. A.* **33**, 7699⁷.—After a connected account of work previously reported, its bearing on the probable processes that have resulted in the terrestrial formation of similar minerals is discussed, including those connected with condensation from the primordial nebula, those occurring under high pressures in the depths of the earth, etc. Several photomicrographs of the products are given. C. A. Silberrad

Identification of diamond in the Canyon Diablo iron. C. J. Ksanda. *Am. Mineral.* **24**, 677–80(1939).—Black grains, from 0.1 to 0.9 mm. in diam., were identified as diamond by x-ray and microscopic examn. C. H. Hale

Variation of hardness in the diamond. Edward H. Kraus and Chester B. Slawson. *Am. Mineral.* **24**, 661–76(1939).—Crystallographic theory explains the experience of diamond cutters; facets parallel to cube faces are easiest to polish or grind; those parallel to the rhombic dodecahedron are somewhat harder. Facets nearly parallel to the octahedron show greater hardness; when exactly parallel they exhibit max. hardness and no polishing is possible with diamond dust. Growth and soln. phenomena and cleavage are also explained in terms of crystallographic theory. C. H. Hale

Nature and origin of flint. Kenneth P. Oakley. *Science Progress* **34**, 277–86(1939).—A review of the geochemistry of flint with 12 references. J. S. Hepburn

Mineralogical constituents of vredenburgite. S. Deb. *Compt. rend.* **209**, 518–20(1939).—Vredenburgite consists of an intimate union of jacobsite and hausmannite (cf. Fermor, *C. A.* **33**, 2059⁴), the percentage of jacobsite varying from 84.15 to 65.45% in different samples. Though x-rays show no difference in the structure of the jacobsite from that of this mineral when occurring alone, there are distinct differences in the permanent specific magnetization, possibly the result of slight differences in comptn. due to differences in the conditions of formation, which probably resulted from the sepn. into the 2 constituents of an originally homogeneous material through change of temp. and pressure. C. A. Silberrad

Alteration of ilmenite. Joh G. Koenigsberger. *Econ. Geol.* **34**, 811(1939).—K. believes that leucoxene (titanite) is formed from ilmenite by hydrothermal action at 150–250°, not by surface weathering as suggested by Merritt (*C. A.* **33**, 1914⁶). Michael Fleischer

Dolomitization of calcareous sediments. A. Rivière. *Compt. rend.* **209**, 597–9(1939).—The fact that the pH of sea water in contact with $CaCO_3$ decreases, as also the "alkaline reserve" (defined as the no. of cc. of *N* diacid required to neutralize a l. of sea water with an indicator unaffected by CO_2, this indicates the total Ca and Mg in soln as carbonate or bicarbonate) is not explicable as merely due to sepn. of $CaCO_3$ on nuclei thereof from a supersatd. soln. Expts. are described suggesting that the true explanation is based on the fact that $CaCO_3$ in contact with sea water extracts therefrom some of the Mg as $MgCO_3$, partially transforming some of the $CaCO_3$ to $MgCa(CO_3)_2$. Pure chalk left in contact with sea water for 11 months contained 8% dolomite. C. A. S.

Serendibite and associated minerals from the New City Quarry, Riverside, California. Gerald M. Richmond. *Am. Mineral.* **24**, 725–6(1939); cf. *C. A.* **27**, 2653².—The mineral is optically +, $2V$ = nearly 90°; $\alpha = 1.719$; $\beta = 1.722$; $\gamma = 1.724$. Dispersion is extremely strong, r greater than v. C. H. Hale

Demantoid from the ultrabasic rocks of Azerbaidzhan. Mir-Ali-Kashkai. *Compt. rend. acad. sci. U. R. S. S.* **22**, 507–9(1939)(in English).—The comptn. of emerald-green crystals of demantoid from Mt. Shah-Dag (Minor Caucasus) was found to be: SiO_2 34.52, Fe_2O_3 31.33, MgO 0.72 and CaO 33.42%. TiO_2, Cr_2O_3, alkalies and water were not detd. This corresponds to the formula $Ca_3Fe(SiO_4)_3$. Analysis of macroscopically similar crystals differed, indicating an admixt. of andradite. Demantoid is found in much crumpled, metamorphosed serpentinized dunites in the form of thin veinlets in the rock and on the surface of cavities of the ultrabasic Transcaucasus complex. Lester W. Strock

Genesis of montmorillonite and kaolinite and conditions of their joint occurrence in the colloids of soils and clays. I. D. Sedletskii. *Compt. rend. acad. sci. U. R. S. S.* **22**, 510–14(1939)(in English); cf. *C. A.* **32**, 3728⁹.—The minerals montmorillonite, beidelite and sericite constitute the colloids of alk. "solonetz" soils, whereas minerals of the kaolin group are found in the acid "podzol" soils. Solonetz soils from Trans-Volga, the Caspian plain, middle Asia and the Chernigov district; and podzol soils from the Kalinin district, the Moscow district and Kamchatka were investigated. Montmorillonite prevailed in a soda-solonetz whereas beidelite was present in the upper portion of a sulfate-chloride solonetz. The process of desalinization of salt marshes results in a production of $CaCO_3$ from underlying gypsum. Beidelite is found above the gypsum

layers but not below them where the medium is slightly acid. In podzol soils derived from clays, any original montmorillonite is altered to kaolin, which was demonstrated on concretions from Tzikhis-Dziri whose center was alk. and contained montmorillonite. That strata underlying coal beds (org. acid medium) contain kaolin clays was shown for the Uzbekistan deposits. Montmorillonite clays are located in regions which accumulate sol. salts as in Caspian lowlands and the Crimean clays. In general, montmorillonite clays are found in accumulation solonetz regions, while kaolin clays occur in alluvial regions. Lester W. Strock

Action of water on natural index borates at various temperatures. N. M. Selivanova. *Compt. rend. acad. sci. U. R. S. S.* **22**, 499–502(1939)(in English).—The reaction between a 1.5-g. sample of the natural Ca borates: invoite $Ca_2B_6O_{11}.13H_2O$, colemanite $Ca_2B_6O_{11}.5H_2O$ and pandermite $Ca_4B_{20}O_{35}.15H_2O$ and 50 cc. H_2O was studied at 20, 50 and 100°. The ratio of B_2O_3 to CaO in the H_2O always exceeded that of the original mineral which indicates a hydrolysis reaction. The H_3BO_3, $Ca(OH)_2$ and B_2O_3/CaO content of the equil. liquid phase is shown at 20°, 50° and 100° for the 3 minerals. The equil liquids from invoite are richer in H_3BO_3 and $Ca(OH)_2$ than from colemanite solns., so that a mixt. of 2 g. invoite and 1 g. colemanite was transformed to colemanite in 20 days at 20°, in 15 days at 50° and in 10 days at 100°. Similarly 1.5 g. invoite was transformed to pandermite in 15 days at 20°, in 12 days at 50° and in 8 days at 100°. Colemanite transforms more slowly to pandermite. The final products were identified by their chem. analysis, sp. gr. and x-ray diffraction patterns. Corresponding expts: with hydroboracite $CaMgB_6O_{11}.6H_2O$ show that B_2O_3 leaches out to a greater extent than does the bases of which Ca is more easily removed than Mg. Hydroboracite was very slowly transformed into asharite (a hydrous Mg borate). A mixt. of kalihorite ($KMg_2B_{11}O_{19}.9H_2O$), gypsum and H_2O produced hydroboracite and invoite crystals in 10 months at 25°. Lester W. Strock

Barite and celestite in the sedimentary rocks of Sweden. Assar Hadding. *Kgl. Fysiograf. Sallskap Lund, Forh.* **8**, 83–103(1938)(Pub.1939)(in English).—Occurrence and conditions of formation of the minerals in various strata are discussed. Chem analyses and crystallographic data are given for the pyrites. Conclusion: Barite was formed after the deposition of the sediments in which it lies enclosed (cf. below). Chem. analyses and descriptions are given of 2 specimens of celestite from chalk and from gray flint beds. 14 references. **The solubility relations of barium sulfate.** Sven Palmqvist. *Ibid.* 103–9.—The theoretical factors involved are discussed. Conclusion: Ca ions (and also Cl ions) will increase the solv. of $BaSO_4$. 5 references. W. C. Tobie

Pied des Monts uraninite. O. B. Muench. *J. Am. Chem. Soc.* **61**, 2742–4(1939).—The Pb-U ratio was det. as 0.135. This value, when corrected for the common Pb, gives a value of 920 million years for the age of this mineral which is in fairly good agreement with the value calcd from the isotopic detn. of the Pb from this same sample. A. S. Garrett

Oxidation-reduction potentials as applied to the study of the paragenesis of minerals. VI. V. Shcherbin. *Compt. rend. acad. sci. U. R. S. S.* **22**, 503–6(1939)(in English).—The oxidation-reduction potentials of 18 ion pairs are given in v. for a 1 *N* soln. at 18°, including among others: $V^{3+} \rightarrow V^{4+}$ (+0.40 v.); $U^{4+} \rightarrow U^{6+}$ (+0.41 v.); $Fe^{2+} \rightarrow Fe^{3+}$ (+0.75 v.); $Mo^{5+} \rightarrow Mo^{6+}$ (+0.78 v.) and $Pb^{2+} \rightarrow Pb^{4+}$ (+1.80 v.). Any pair is an oxidizer with regard to any other pair of lower pos. potential. The paragenesis of ferrous and ferric compounds is an important guide to the oxidation-reduction state of natural mineral deposits. The ions Ti (3,4); V (3,4); Cr (3); Mo (5,6); Mn (2); Co (2); Ni (2); U (4,6); W (6); and Pb (2) may occur with Fe^{2+} but the ions V (5); Cr (6); Mn (4); Co (3); Ni (3); $(IO_3)^-$; $(SeO_3)^{2-}$; $(NO_3)^-$; and Pb (4) may not occur with Fe^{2+}. The following may occur with Fe^{3+}: Ti (4); V (4,5); Cr (3,6); Mo (5,6); Mn (2,4); Co (2,3); Ni (2,3); U (6); $(IO_3)^-$; $(NO_3)^-$; $(SeO_3)^{2-}$; and Pb (2,4), but Ti (3); V (3); U (4) may not occur with Fe^{3+}. A table is given showing graphically the effect of various ions on each other which is shown to explain the paragenesis of mineral deposits, e. g., Chili "Caliche" beds, blanket ores and the V beds of Sulelman-Saya and Ottavi in which V^{5+} occurs. The genesis of ilzemanite, the formation of stichtite and volkonskoite instead of crocoite when chromite weathers, and failure of V to concentrate in weathering zones of Ural titanomagnetites is explained. Lester W. Strock

Metasomatism of the country near ore-bodies and its possible economic significance. E. de C. Clarke and H. A. Ellis. *Econ. Geol.* **34**, 777–89(1939).—The need for quant. study of the relations between ore abundance and metasomatism is pointed out. The relations existing in the Au mines in W. Australia are summarized. M. F.

Auriferous quartz veins in the Dharwar formation in the western Raichur Doab. S. K. Mukerjee. *J. Hyderabad Geol. Survey* **3**, Pt. 2, 50–88(1939); cf. Krishnamurthy, *C. A.* **32**, 7376⁷.—The area consists almost entirely of schists, gneisses, charnockites, etc. It is intersected by quartz veins, in places auriferous. One vein contains pyrite, arsenopyrite, pyrrhotite, tourmaline and a very little galena, and another chalcopyrite, malachite and Fe ores, but always in small quantities. The origin of the Au and other ores is discussed, and considered to be connected with dioritic and dolerite dikes. C. A. S

A silver-pitchblende deposit at Contact Lake, Great Bear Lake area, Canada. G. M. Furnival. *Econ. Geol.* **34**, 739–76(1939); cf. *C. A.* **33**, 6760⁶.—Several stages of mineral deposition, some sepd. by periods of marked deformation, are recognized. Granodiorite was altered with the formation of chlorite, garnet and much hematite. Dark-gray quartz veins with pyrite, chalcopyrite and arsenopyrite were then intruded, followed by white comb quartz accompanied by much hematite. The vein system was again deformed and carbonates were introduced accompanied by metallic minerals, the paragenetic succession being pitchblende, Co-Ni minerals (cobaltite, safflorite, rammelsbergite, niccolite, breithauptite), Cu and Ag minerals (tetrahedrite, bornite, chalcopyrite, chalcocite, stromeyerite, pearceite), native Bi and native Ag. The early period of mineral formation was high-temp., the later mesothermal, Ag having crystd above 200°. An analysis of the pitchblende gave U 26.31, Pb 2.44, Th trace, which places the age at about 650 million years. Twelve photomicrographs. Michael Fleischer

Manganese mineralization at Tombstone, Arizona. Charles A. Rasor. *Econ. Geol.* **34**, 790–803(1939).—Irregular pipe-like bodies of Mn oxides occurred at intersections of mineralized fissures with steep faults. The ore had a soft core of Fe and Mn oxides with considerable Ag and some Pb and Zn. This core was surrounded by hard, compact Mn oxides, chiefly psilomelane and polianite. Hetaerolite ($ZnMn_2O_4$), pyrolusite and manganiferous carbonates were also present, along with an unknown isotropic mineral contg. Mn and As. All the oxides were probably derived from a single primary Mn mineral, alabandite (MnS). This was oxidized, Mn was transported as sulfate, and ppted. as oxides by limestone in the presence of air. Optical data are given for hetaerolite and the unknown mineral. Michael Fleischer

Asbestos and chromite-deposits of Wyoming. R. H. Beckwith. *Econ. Geol.* **34**, 812–43(1939).—Numerous chrysotile asbestos deposits are described. All are in serpentine near granitic intrusions. Most of the material is short-fibered and some is brittle. Hardness and brittleness in chrysotile are shown by microscopic study to be due to the presence of streaks of silica parallel to the fiber length (cf. Sobolev and Tatarinova, *C. A.* **26**, 3756; **27**, 2400). Chromite occurs at Casper Mt. disseminated in bands and lenses in tremolite-chlorite-talc schist. The best ore requires concn. to meet market requirements. Also in *Geol. Survey Wyo. Bull.* No. 29, 32 pp. (1939). Michael Fleischer

Barite deposit at Pessens near Rodez (Aveyron). J. Durand and E. Raguin. *Bull. soc. géol. France* **8**, 755–64 (1938).—The deposit yielded 100,000 tons in the past 10

years. As extd. the material contains 30% of clay and limestone. Borings show it to extend horizontally over about 50 acres at a shallow depth. Where worked it is 1–2 m. thick, beds of pure barite being intercalated in yellowish marly or siliceous (jasperoid) liassic strata; the latter has resulted from silicification of a dolomitic limestone. Silicification was followed by introduction of the barite by hot solns. The deposit is an extreme case of metasomatosis. More or less similar deposits are fairly common in the neighborhood, the barite in places being accompanied by sulfides, e. g., the deposit at St. Rome-de-Tarn contains sphalerite, galena and chalcopyrite.
C. A. Silberrad

The brown-coal district in northwestern Bohemia. Fritz Pohl. *Z. Berg-, Hütten- u. Salinenw. deut. Reich.* 86, 475–80(1938).—Details of the geol. compn. with special reference to the occurrence, origin and character of the coal found in this district. S. Landeker

Mineral deposits in the Sudeten area. W. E. Petrascheck. *Z. Berg-, Hütten- u. Salinenw. deut. Reich.* 86, 444–74(1938).—A geol. review with details of the occurrence of combustible substances, of ores, minerals and clays. S. Landeker

Magmatic cycles and orogenic epochs. J. H. F. Umbgrove. *Geol Mag.* 76, 444–50(1939).—A discussion, with summary of previous views, offering an explanation of the fact that basic or ultrabasic rocks characterize the axes of geosynclines, acid rocks not appearing at that stage of development. C. A. Silberrad

Graphic granite. Ernest E. Wahlstrom. *Am. Mineral.* 24, 681–98(1939).—Quartz pencils in feldspar form the pattern described variously as graphic granite, runite and Hebraic pegmatite. Bersmann's statement (*Z. Krist.* 69, 77–104(1928)) that the quartz is oriented with a trapezohedron zone coincident with the prism zone of the feldspar is not confirmed by W. Examn. of 30 specimens indicates that there is no consistent orientation of the quartz in the feldspar. Replacement of feldspar by quartz is probably the dominant process in graphic granite formation rather than simultaneous crystn. (cf. Vogt, *C. A.* 26, 5881). C. H. Hale

Granites of the Black Mountain and south Cevennes. Albert Michel-Lévy. *Bull. soc. géol. France* 9, 93–6 (1939).—Complete and proximate analyses of 7 "granites" from this neighborhood are given. They include 3 granites proper; 2 connected laccolitic injections (formerly designated "porphyroids"), characterized by, probably pneumatolytic, increase in alkali; and 2 mylonites (formerly termed blavierites) probably derived from arkoses rather than from granites. The compns. are compared and discussed. C. A. Silberrad

Comparative composition-variation diagrams for the Cainozoic igneous rocks of New Zealand with determinations of the optic axial angles of the pyroxenes and olivines contained therein. W. N. Benson and F. J. Turner. *Trans. Proc. Roy. Soc. New Zealand* 69, Pt. 1, 56–72 (1939).—Optic axial angles were measured for 165 pyroxenes and 64 olivines in thin sections of 39 rocks, mostly olivine-basalts. Very little pigeonite was observed. The results are compared with those of Barth (*C. A.* 25, 5120, 5369), Tsuboi (*C. A.* 27, 686) and Kuno (*C. A.* 30, 6678[8]) on other Pacific rocks. Five new rock analyses.
Michael Fleischer

Deccan trap from the Gulbarga and Osmanabad districts. C. Mahadevan and L. S. Krishnamurthy. *J. Hyderabad Geol. Survey* 3, Pt. 2, 24–49(1938).—Petrological descriptions and porosity detns. of many samples are given. C. A. Silberrad

New type of metamorphic rocks (sakenites) in crystalline schists of south Madagascar. Alfred Lacroix. *Compt. rend.* 209, 609–12(1939).—The sakenites occur at Sakény (Ihosy, Madagascar) as a series of beds up to 10 m. thick, and in one case extending over 5 km., in paragneisses contg. much aluminous mineral (sillimanite, cordierite, almandine, etc.), assocd. with pyroxenites and amphibolites. They are whitish, hard, saccharoidal rocks; the predominant constituent is anorthite or a near plagioclase, assocd. with very aluminous minerals—sapphirine and (or) spinel, and with the latter sometimes corundum and diaspore. In exceptional cases the rock consists of anorthite with practically only corundum, which may occasionally even predominate over the anorthite; elsewhere it may consist almost solely of anorthite. The various types pass into one another with no definite lines of sepn. C. A. Silberrad

Sandy muds and muddy sands. Jacques Bourcart and Claude Francis Boeuf. *Compt. rend.* 209, 568–70(1939); cf. following abstr.—Muddy sand from the Aber (Roscoff) is yellow to a depth of about 1 cm. and below that gray to black. It is composed of varying proportions of (I) sandy material (quartz, tourmaline, micas, etc.) and of (II) mud consisting of fine sand, remains of shells and algae; I and the upper portion of II contain an abundant fauna, and II is characterized by the presence of sulfides, especially of Fe. I placed with sea water in a closed vessel in darkness absorbs O and blackens, but exposed to light it becomes yellow again and evolves some O. The proportion of algae varies from place to place. C. A. S.

Estuary mud. Jacques Bourcart. *Compt. rend.* 209, 542–4(1939); cf. *C. A.* 33, 4918[2].—B. distinguishes, as opposed to "limon" mud resulting from an inundation, and "boue" oceanic mud, "vase," the muds of estuaries along the Atlantic coast of Europe from the Seine to the Gulf of Guinea. These consist of about 70% of inorg. material, partly sandy (diam. of grains 0.1–0.02 mm.) and partly pulverulent (less than 0.02 mm.), which latter may be quartzose or calcareous, with accessory clay minerals. For the remaining 30% the name *algon* is proposed; it consists of finely divided remains of algae or, in the upper parts of the estuary, of land vegetation; it forms a viscous binding material and always contains Fe and evolves H_2S when kept moist. C. A. Silberrad

Lacustrine investigations in the Gaspe Peninsula. A. J. M. Honeyman. *Can. J. Research* 17, D, 212–24(1939).—A study of temp. variations in Ross Lake indicates that it is a typical "second order" lake. The seasonal variations are explicable in terms of the changes of air temp. and the resulting effects on temp. and d. of the water. Thermal stratification is clearly indicated. Seasonal variations in the dissolved O content of the water are largely dependent on temp. changes. The variations in acidity, alky. and pH are dependent chiefly on temp. changes affecting soly. of CO_2, and on the limy nature of the lake bottom. Analysis of the O distribution indicates a eutrophic condition, but there is as yet insufficient quant. information about the biol. conditions to warrant definite conclusions. J. W. Shipley

Water in the Tanezruft. Nicolas Menchikoff. *Compt. rend.* 209, 44–6(1939).—It is probable that below the impermeable surface stratum of greenish salty marl, contg. gypsum and pyrite, there is a water-bearing stratum of sandstone, below which are impermeable cryst. rocks—gneiss, mica schist, etc.—with granitic and rhyolitic intrusions. C. A. Silberrad

Occurrence of sillimanite in Travancore (Singh) 19.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Metallurgical education. Robert F. Mehl. *Metals & Alloys* 10, No. 10, A-56, 52(1939).—A review of ten years' progress. 3 references. I. Hartmann

Powder metallurgy. Fred P. Peters. *Metals & Alloys* 10, No. 10, A-74, 76(1939).—A review of ten years' progress. 4 references. I. Hartmann

Problems in Swedish mining practice. J. Kempe. *Jernkontorets Ann.* **123**, 285–336(1939).—Mainly a discussion of costs of various practices in the mining, transportation, handling and concn. of ores. H. C. Duus

Production problems in pig iron manufacture and direct steel-making processes. Edvin Fornander. *Jernkontorets Ann.* **123**, 337–52, 365–85(1939).—A statistical discussion is given of total production blast furnaces in operation, production per furnace, yields, and fuel requirements. Profile drawings of various furnaces are given. Methods of conserving heat are noted. Data are taken from actual Swedish operations. H. C. D. 2

Some aspects of tin research. II. C. O Bannister. *Science Progress* **34**, 302–5(1939); cf. *C. A.*, **32**, 6595⁷. A review of recent researches on the industrial applications of tin and the chemistry involved therein. J. S. H. 3

Open-hearth practice. Leo F. Reinartz. *Metals & Alloys* **10**, No. 10, A-52, 54(1939); cf. *C. A.* **33**, 1640⁶. A review of ten years' progress. 9 references. I. H 4

Waste problems in the nonferrous smelting industry. Robert E. Swain. *Ind. Eng. Chem.* **31**, 1358–60(1939).—A review. S, As, Cd and the rarer elements, and slag are considered. G. G. 5

Waste problems of the iron and steel industries. Willard W. Hodge. *Ind. Eng. Chem.* **31**, 1364–80(1939). The rapid growth of the steel industry from a production in the U. S. A. of 11,838 gross tons of steel in 1860 to 56,433,473 tons in 1929, and of coke from 13,333,714 short tons in 1895 to 59,883,845 tons in 1929 has brought problems in the disposal of wastes, among them being slags, flue dust, ammonia liquor, coal tar, phenolic liquors, H_2S, waste pickle liquor and other materials. Data, tabulated and graphical, are given on production of pig iron, steel, coke, tin and terne plate, slags and flue dust; also chem. analyses of pig iron, blast-furnace, open-hearth and elec. furnace slags, and of spent pickle liquors. Brief reviews are given of processes for the recovery and utilization of slags, flue dust, ammonia and phenolic liquors, H_2S from fuel gases, and products from coal tar. The waste pickle liquor problem (approx. 800,000,000 gallons per year) is treated in more detail, short outlines being given of 12 methods of disposal and some 40 processes for treating the liquors with recovery of by-products. The processes are classified into 10 groups based on by-products recovered, as follows: (1) copperas or siderotilate, (2) copperas and the free H_2SO_4, (3) $FeSO_4.1^1/_2H_2O$ and free H_2SO_4, (4) ferric sulfate and H_2SO_4, (5) H_2SO_4 and iron oxide, (6) electrolytic iron and H_2SO_4, (7) iron oxide for paint pigments and (or) polishing rouge, (8) "Ferron," (9) $(NH_4)_2SO_4$ and iron oxide, sulfide or carbonate, and (10) miscellaneous processes for making other inorg. compds., such as, Na sulfate, Ba sulfate, natrojarosite, and iron phosphate. Wholly inadequate markets for the easily recovered by-products has mitigated against the general installation of waste pickle liquor treating processes by the iron and steel companies. The recent trend toward the use of chlorinated copperas or waste-pickle liquor, and of ferric sulfate in the treatment of water supplies, sewage, and certain org. wastes, is summarized. The general relations of the major waste-disposal problems; sewage, acid mine drainage, anthracite culm, oil-field brines, and wastes from the metallurgical, org. and inorg. manufg. industries are briefly discussed. Much research work is in progress on the waste pickle liquor problem and marked improvements have recently been reported on 5 processes; also possible new uses for the by-products are under intensive investigation. The importance of abatement of stream pollution and recovery of useful by-products from industrial wastes are emphasized as essential to a national economy in the utilization of unreplaceable natural resources. 139 references. W. W. Hodge 6 7 8 9

Problems of Swedish steel production. S. En v. Hofsten. *Jernkontorets Ann.* **123**, 353–85(1939).—Discussion of trends in manuf. with reference to acid Martin, basic Martin, Thomas, acid Bessemer, and electro-processes. Electro-processes are developing rapidly, especially with reference to high-frequency induction furnaces. The significance of various factors for production of quality steel is discussed, such as the grade of raw material, the use of sponge iron, the classification of scrap, and influence of alloying constituents. H. G. Duus

Manufacture of rimming steel by the acid Bessemer process. T. Swinden and F. B. Cawley. *Iron & Coal Trades Rev.* **139**, 443–4(1939); cf. *C. A.* **33**, 8153⁹.—The application of the process at a British steel plant is described. Also in *Engineering* **148**, 482–3(1939). I. Hartmann

Recent advances in industrial metal finishing. E. E. Halls. *Ind. Chemist* **15**, 351–3(1939). E. H

Testing of materials for workability. Walter Reichel *Tech. Zentr. prakt. Metallbearbeit.* **48**, 291–5, 359–62 (1938).—"Workability testing," a new method for testing materials for metal cutting, is described. S. Landeker

Some fatigue problems of the railroad industry. R. W Clyne. *Metals & Alloys* **10**, 316–23(1939); cf. *C. A.* **33**, 7706⁹, 8508⁹.—The majority of railroad springs fail by progressive fracture. The fatigue crack almost always originates at some point on the inside diam. of helical springs; the point of origin is always on the tension side of elliptic spring plates and usually at one of the corners. The surface factors which most severely affect the fatigue resistance of hot-formed spring steels are notches and decarburization, both chemically (corrosively) and mechanically formed notches are of equal importance. Car wheels often fail by disintegration of the tread metal due to fatigue. The defect occurs by means of progressive fracture and is usually found in comparatively soft wheels which operate under heavy axle loads. The fracture may originate at the surface or at some subsurface non-homogeneity, and is due to a combination of effects of stress concn. and static and impact loads. 4 references I. Hartmann

Method of determining the ultimate deformation and ultimate strain in creeping. I. A. Oding *Zavodskaya Lab.* **8**, 856–9(1939). On the basis of an analysis of creep curves O. offers a method for detg. ultimate deformation and ultimate strain in creep by the graphical treatment of the diagram of elongation. It is claimed that these 2 characteristics make it possible to det. the max. length of service of an object under given strain and speed of creep provided the material is not subject to phase or structure changes or intercryst. phenomena which may also result in sudden failure of the object. B. Z. K. 10

Rapid method of regulating oxidation. P. A Rozhdestvenskii. *Zavodskaya Lab.* **8**, 296–8(1939).—The anticorrosion resistance of objects was judged by measuring the e. m. f. between the oxidized specimens and Pt in 0.95% NaCl soln. at 20°. The results are given in graphs. A diagram of the app. is included. B. Z. K. 11

Technique for the x-ray powder photography of reactive metals and alloys, with special reference to the lattice spacing of magnesium at high temperatures. G. V. Raynor and W. Hume-Rothery. *J. Inst. Metals* **65**, Advance copy No. 851, 9 pp.(1939).—Filings of Mg were prepd. in an atm. of A, then sieved and sealed in thin silica capillaries. This arrangement permitted taking lattice measurements up to 400°. For higher temps. up to 500° it was necessary to mix the filings with medicinal paraffin in sealed capillaries. By using thin rods of Mg in silica capillaries R. and H. were able to extend the work to 597°. At low temp. the expansion is approx. proportional to the temp., but above 300° a departure from linearity becomes more pronounced. This temp. is about 63% of the abs. m. p. H. S. v. K. 12

Sintering of copper and tin powders. H. E. Hall. *Metals & Alloys* **10**, 297–8(1939).—Representative samples of Cu and Sn powders of a grade extensively used by bearing manufacturers were mixed with graphite in definite proportions and then compressed at 60,000 lb. per sq. in. to give a bearing approx. 1 in. long, $^3/_4$ in diam. with a $^3/_{32}$ in. wall. After compression the bearings

were heated by sintering at 810°. The bushings were removed at various time intervals to provide a series of bushings that had been subjected to progressively increasing sintering times. The bushings were then sectioned, polished, suitably etched and typically representative fields were photographed at a magnification of 400X on Kodachrome film, to show the various structural stages in the process. Six colored photomicrographs are given.
I. Hartmann

Deformation and heat-treatment of rods of Al-Cu-Mg and Al-Mg-Si alloys. R. Lay and A. Grimm. *Aluminium* 21, 627–37 (1939).—An investigation into the relation of grain size and mech. properties and the degree of reduction in drawing rods and of heat-treatment. The generally accepted rule is that in the manufg. process the finest possible grain should be obtained, for then the anisotropic nature of the individual grain becomes of minor importance and the quasi-isotropic state exists which is detg. for the uniformity of deformation; with coarse grain the vectorial properties of the single grain are predominant and produce scarry, uneven surfaces with a decrease in mech. strength. The present investigation has, however, shown that too fine a grain can also lead to mech. difficulties in Al-Cu-Mg and Al-Mg-Si rods, just as it does in sheets. This occurs particularly in extruding processes where very coarse recrystns. take place under crit. deformations and tensile strength is reduced. The normal values can nearly be restored later by annealing of long duration at hardening temps. whereby the temp. of the quenching bath also has some influence. The highest mech. strength is obtained in fully hardened material by stretching, the higher the degree of stretching (rolling) the higher become elastic limit and tensile strength, while elongation reduces only slightly. M. Hartenheim

Heat-treating in boiler and apparatus construction. E. Schulz and O. Niezoldi. *Arch. Warmewirt.* 20, 141–6 (1939).—Stress-relieved, normalized, and untreated welds in boiler steels were examd. microscopically, by mech. tests, and for corrosion resistance against strong caustic and concd. boiler water, both with and without previous cold work. Though differences in grain size were observable, there was not, on the whole, any difference in result between the 2 types of heat-treatment. F. W. Thiele

Role of nickel in the machine tool industry. J. W. Sands and D. A. Nemser. *Metals & Alloys* 10, 260–8, 311–15 (1939). The effects of the addn. of Ni, Cr and Mo to cast iron and to steel are described. When added to cast iron, Ni like Si acts as a chill reducer; unlike Si, however, Ni controls chill without appreciably coarsening the graphitic structure or grain, without lowering the strength, without decreasing machinability or introducing internal casting stresses. Cr resembles Ni in some features with respect to its effect on iron. It refines the graphite structure of iron and hardens and strengthens it, but Cr increases chilling tendency and promotes the formation of free carbide. Cr, however, acts to build up combined C and Fe and this feature renders it useful in conjunction with Ni in casting of heavy sections. Mo is helpful in increasing strength and toughness of iron; it increases chilling tendency slightly, but not as much as Cr. By alloying cast iron with Ni or with Ni and Cr or Mo, together with appropriate adjustments of the base compn., it is possible to increase greatly the tensile strength and also the elastic modulus of the iron. Ni is completely sol. in the ferrite constituent of steel which it strengthens and toughens without loss of ductility; its effect is independent of the C content of the steel. Ni also lowers the crit. temp. of steel, permitting certain heat-treating operations to be carried out at lower temps.; it also reduces the min. cooling rate required for the development of full hardness on quenching. Ni increases the strength properties of most of the common bronzes, and it raises the proportional limit and yield point. It also increases the fluidity in bronze casting mixts., reduces the tendency toward formation of intercryst. shrinkage pores, and refines the grain structure.
I. Hartmann

Nickel castings. M. Herve. *Métallurgie* 71, 21–4 (Spec. Ed., May, 1939).—The influence of Ni is discussed in: counteracting heterogeneity (e. g., Ni:Cr = 3:1); in increasing the mech. properties of gray cast irons (1–3% Ni); in increasing hardenability in castings (2 to 4% Ni); in increasing hardness of white cast iron (3 to 5% Ni); in increasing the corrosion resistance (12 to 15% Ni, 2 to 3% Cr; sometimes 5% Cu); in increasing the high-temp. resistance (1 to 3% Ni, 0.5 to 2% Cr); in rendering white cast iron nonmagnetic (7 to 10% Ni, 4 to 6% Cr).

Kinetics of decomposition of austenites in the upper portion of the intermediate domain. Henri Jolivet and Albert Portevin. *Compt. rend.* 209, 556–8 (1939); cf. *C. A.* 33, 8157⁴.—Further dilatation-time curves are given for (1) a steel of compn. C 0.7%, Mn 0.7, Cr 1.0 and Mo 0.6, showing the decompn. of the austenite to be incomplete after 50 hrs. at 475° or 450°, but complete after 10 min. at 400° and (2) a steel of compn. C 0.6%, Ni 2.7%, Cr 0.7% and Mo 0.6 showing the pearlitic transformation of the residual portion at 600° or 625° to be markedly slackened by a preliminary 8 min. at 400° and quite suppressed for 4 hrs. by 15 min. at that temp.
C. A. Silberrad

Method of determining the number of graphitization centers in malleable cast iron. S. A. Saltykov. *Zavodskaya Lab.* 8, 428–31 (1939).—The formulas suggested by Schwartz (*Metals & Alloys* 7, 278 (1936)) for calcg. the no. of graphitization centers in malleable cast irons are not applicable for cases where the no. of centers has been artificially increased. Instead the following formula is offered relating the no. of graphitization centers per cc. (N) to the no. of centers/sq. mm. (n): $N = 2.38n^{1.5}$. The formula was applied to malleable iron specimens and gave satisfactory results. The av. distance (c) between the centers can be calcd. from $N = \sqrt{2}/c^3$.
B. Z. K.

The influence of temperature on the carbon-oxygen equilibrium in molten steel. G. Phragmén and B. Kalling. *Jernkontorets Ann.* 123, 199–221 (1939).—The equil. was measured experimentally in a high-frequency vacuum furnace with 400 g. molten iron in a crucible of MgO or Al_2O_3. C was added in amts. slightly above or below the expected equil. values. Analyzed mixts. of CO and CO_2 were passed over the mass. Expts. were run at

1550° and 1700° measured by an optical pyrometer. After exposure for 2-4 hrs. the reaction mass was cooled and analyzed. The original sample had the compn. C 0.027, Mn 0.07, S 0.014 and P 0.01%. At 1550° the equil. values were 0.07% C with 2.5% CO_2, 0.035% C with 5% CO_2, and 2.02% C with 7.5% CO_2. At 1700° the values were 0.07% C with 1.7% CO_2, 0.03% C with 3.4% CO_2, and 0.02% C with 5% CO_2. Phase-rule diagrams were constructed for the system on the basis of the above results. H. C. Dews

"Alnico" and related alloys. The metallurgical story. Edwin F. Cone. *Metals & Alloys* **10**, 293-7(1939).—The development of magnetic alloys, their magnetic properties and uses are reviewed briefly; special emphasis is placed on Ni-Al-Co-Fe alloys. The chem. compn of these alloys averages about as follows: Alnico, 20% Ni, 12% Al, and 5% Co, balance Fe; so-called "Alnico," 25% Ni, 12% Al, and balance Fe. The C should range from 0.02 to 0.06%, the Si and Mn from 0 to 0.10% each, or as low as possible and not over 0.15%. To secure the max. magnetic properties, the Alnico castings must be submitted to a definite, carefully controlled heating cycle, inasmuch as Alnico is a pptn.-hardening alloy. It is first heated to a high temp. for a soln. treatment and from this temp. it is cooled at a definite detd. rate to approx. 700°, this rate of cooling depending entirely upon the compn. of the Alnico. Alnico has a coercive force of 400 to 440, with a residual value between 7000 and 7500. I. Hartmann

The examination of the grain of aluminum alloys. Karl Altmannsberger. *Tech. Zentr. prakt. Metallbearbeit.* **48**, 394, 396-7(1938).—In order not to damage the grain, special precautions must be used. A table shows the influence of the compn. of the alloy on the appearance (microscope) of the unetched ground section. S. L.

Low-lead silver alloys for bearings. Some properties pertinent to their use. R. W. Dayton. *Metals & Alloys* **10**, 306-10, 324(1939); cf. *C. A.* **33**, 1646⁴.—Six Ag alloys contg. 0 to 5% Pb were prepd. from double-refined Ag (99.995% Ag) and test Pb. Two melts of each alloy were made, and two bars 3/4 in. diam. and 2 in. long were cast from each melt. The seizure resistance of the alloys was detd. in 4 different conditions of heat-treatment; the corrosion resistance was examd.; the phys. properties, hardness, shear strength and fatigue strength were detd.; and the best lining methods were studied. The test results indicate that bearings made of a Pb-Ag alloy (3 to 4% Pb) are extremely seizure resistant, and have the necessary phys. properties to enable them to carry high loads without mech. failure. The best method of bonding Pb-Ag alloys to steel is by electrodeposition 4 references. I. Hartmann

Silver and its alloys for the arts and industries. J. L. Christie and Don Graf. *Metals & Alloys* **10**, 300-5 (1939).—A review of the uses of Ag, with 16 photographs illustrating typical steps through which Ag and its alloys go during production before release of the final manufd. article. I. Hartmann

The crystal chemistry of tantalum alloys. F. Laves and H. J. Wallbaum. *Naturwissenschaften* **27**, 674-5(1939). —Metallic compds. of type AB_2 will crystallize with 12g6 symmetry ($MgCu_2$, etc.) if the at. radii ratio is about $\sqrt{3}/\sqrt{2} = 1.23$ (*C. A.* **33**, 4175⁶, 9080⁶). $TiMn_2$, $TiFe_2$ and $TiCo_2$ are of 12g6 type, $TiFe_2$ has $a = 4.81$, $c = 7.88$, $c/a = 1.638$. $TiNi_3$, $TiCu_3$ and $TiZn_3$ are of dense spherical packing, $TiNi_3$ has a new structural type, $TiCu_3$ has deformed hexagonal ball packing, $TiZn_3$ is of $AuCu_3$ type with $a = 3.023$. The x-ray diagram of $TiGa_3$ is much like that of $TiZn_3$. In the series of Ti alloys with low Ti content the 12g6 type becomes unstable between Co and Ni. For higher Ti contents compds. of the CsCl type are found: FeTi, CoTi, NiTi, ZnTi. There is no CuTi although there appears to be a Cu-Ti alloy of compn. near 1:1. The highest Ti content is found in the isomorphic alloys $MnTi_3$, $FeTi_3$, $CoTi_3$, $NiTi_3$ and $CuTi_3$; they are cubic, face-centered, with 96 atoms per cell. Replacement of Fe or Ni in Ti alloys by Ru, Os or Pd and Pt produces RuTi and OsTi like FeTi in structure, Pd_3Ti, and Pt_3Ti of Ni_3Ti and Zn_3Ti structure, resp. No PdTi or PtTi is found but isomorphous compds. Pd_3Ti_2 and Pt_3Ti_2 of unknown structure appear. $PdTi_2$ and $PtTi_2$ are of $NiTi_2$ structure. In the system Ag-Ti there is no compd., with Au $AuTi_3$ of the $AuCu_3$ type is formed. Results on Rh and Ir alloys will be published later. B. J. C. van der Hoeven

The development of zinc alloys since 1900 Arthur Burkhardt. *Giesserei* **26**, 484-7, 505-8(1939). E. H.

System γ-iron-carbon. J. Seigle. *Rev. ind. minérale* No. **443**, 293-302; No. **444**, 303-24(1939).—The constitution of the Fe-C alloys between 925 and 1500° is discussed, the chief points being the nature and soly. of cementite, whether it exists in various forms, e. g., $(Fe_3C)_n$, and its stability, whether to the liquidus or decompg. at a lower temp., e. g., about 1300°; the soly. of C as such in Fe, its nature in soln., whether cryst. amorphous or colloidal, and how far this is dependent on the original form of the C. It is also suggested that diamonds of useful size might be produced by seeding a soln. of C in molten Fe with minute diamond particles. Previous investigations and constitutional diagrams are discussed. C. A. Silberrad

Concentration of hydrogen ions in galvanic zinc baths. F. K. Fisher and D. A. Timofeev. *Zavodskaya Lab.* **8**, 276-9(1939).—Tests with H_2, glass and quinhydrone electrodes for detg. H-ion concn. in galvanic Zn baths showed that the last method was most suited for use from the point of view of simplicity of arrangement and technique of manipulation. The potential is established very rapidly (about 3 min.) and the time for a detn. requires 5-8 min. The results are somewhat higher than those obtained by the H_2 and glass electrodes and the readings should be reduced by 0.1 pH. B. Z. Kamush

Corrosion- and heat-resisting steels. W. B. Thompson. *Can. Metals Met. Inds.* **2**, 252-4, 256(1939).—A discussion of certain details of manuf. of some of the stainless alloys, particularly from the casting standpoint. The 18-8 (Cr-Ni) steels have been modified by addns. of Mo, Si, W, Ti or Cb. With the exception of the Mo alloy facilitation of the fabrication of equipment, which, owing to large or irregular size, and thin or uneven sections, is not available to subsequent heat-treatment. A Cb-bearing 18-8 alloy is effective in solving the problem of intergranular corrosion. The Cb content is 10 times the C content. KA2-M0 castings are widely used on account of their resistance to corrosive attack. The compn. is Cr 19-20, Ni 9-10, Mo 3 and C 0.11-0.15%. Intermediate alloys contg. 4-6% Cr, 0.10-0.15% C and 0.5% Mo, 1% W or 0.60-0.70% Ti or Cb possess properties that tend to lessen air-hardening, low toughness and embrittlement, resist mild corrosion at moderately elevated temps., and are extensively used in the oil-refining industry for cracking tubes, tube sheets, valves, etc. Heat-resisting alloys contain higher proportion of Cr and Ni. The 28% Cr, 15% Ni alloy is popular in Canada. Claims are made for alloy addns. similar to those of the corrosion-resisting group. The alloy agents are N, Ti, Cb, W and Al. W. H. Boynton

Aluminum steels resisting corrosion at elevated temperatures. R. Vernier. *Métallurgie* **71**, 15-19(Special Ed., May, 1939).—Alited Fe has Al diffused into the surface by a cementation process. Al oxide forms a protective film. In practical application this material can be used up to 1100°. Al-Fe alloys with 8% Al oxidize 15 times less than pure Fe at 900-1000° during the same period. For a given temp. in order to obtain the same oxidation resistance less Al (by weight) has to be added than either Cr or Si. With increasing temp. this difference is increasingly favorable for Al. Fe-Cr-Al, Cr-Al-Co, Cr-Al-Si, Cr-Mo-Al and Ni-Cr-Al steels are discussed and their applications given. R. P. Seelig

Maintenance of reciprocating parts. (Use of bronze welding in the industry.) C. H. S. Tupholme. *Cold Storage Produce Rev.* **42**, 61-2(1939).—Resurfacing of worn pistons and other moving parts is possible by an application of wear-resisting bronze welding rods to the worn surface and subsequent machining to original size.

Different welding rod compns. are discussed and details of the welding process are given. On steel parts subjected to severe alternating tension and compression stresses bronze-welding should be applied only once, but cast iron parts can be resurfaced as often as desired.

S. Landeker

Welding of some special steels. Schill. *Bull. assoc. franç. techniciens pétrol.* No. 45, 69–98(1938).—The welding of 5 noncorrosive steels, viz., Cr-Cu-Mn (0.34% Cr), Chromesco Cr-Mn (0.36% Cr), 4–6% Cr-Mo, ferritic steel contg. 12–14% Cr, and an 18–8 austenitic steel is discussed from the welder's point of view. Analytical data of the steels are tabulated. The article is replete with photomicrographs of the various steels.

E. J. Mahler

Long carbon arc welding of copper and copper alloys. W. C. Swift. *Welding Engr.* 23, No. 12, 30–3(1938).—The metal is shielded effectively by CO_2. Rapid cooling of the weld area inhibits segregation of Cu_2O. Six photographs.

Heyer, Robert H.: Engineering Physical Metallurgy. New York: D. Van Nostrand Co., Inc. 549 pp.

Apparatus for grinding ores with chains and water and separating rock fines by flotation. John Youngman and Harry R. Culp. U. S. 2,171,296, Aug. 29. Various structural, mech. and operative details.

Revolving-drum apparatus for reducing ores. Harlowe Hardinge (to Hardinge Co.) U. S. 2,171,298, Aug. 29. Various structural details.

Melting up light metal scrap. Erich Junker and Wuhbald Leugebel. U. S. 2,170,863, Aug. 29. Light metal scrap such as that of Al or Mg is melted up at a temp. below 690° in the presence of a flux contg. NaCl, cryolite and $BaCl_2$ proportioned to melt between about 520° and 690°.

Process and apparatus for removing surface metal from a billet, etc., by the progressive application of streams of oxidizing gas. Homer W. Jones, James H. Buckman and Edmund A. Doyle (to the Linde Air Products Co.) Brit. 507,262, June 13, 1939.

Method and furnaces for extracting iron and other metals. Hans Gallusser. Brit. 507,494, June 15, 1939. Metal oxides, particularly Fe ores, together with the materials for reduction are heated in a closed metal vessel the annular walls of which form the secondary winding of a transformer with a closed Fe path. The vessel is a horizontal rotary drum and is half filled with the mixt. The furnace forms the subject matter of Brit. 507,531, June 15, 1939, divided on 507,494. In Brit. 507,581, June 16, 1939, addn. to 507,494, a closed metal vessel the annular wall of which forms the secondary winding of a transformer with a closed Fe path is partly filled with an oxide of a metal or nonmetal and is rotated during the heating of the charge by currents induced in the vessel wall, H being supplied to the vessel during rotation to reduce the oxide and the resultant H_2O vapor being conducted away. The H is supplied through the shaft supporting the vessel to a preheating pipe located in the vessel and leading to valves that are periodically immersed in the charge and are under electromagnetic control so that H is fed to the charge when the valve is immersed therein and H_2O vapor flows to a condenser when the valve is uncovered. H carried over to the condenser is returned to the furnace. The furnace forms the subject matter of Brit. 507,532, June 16, 1939, divided on 507,581 and addn. to 507,531.

Blast-furnace operation. Herman A. Brassert (to H. A. Brassert & Co.). U. S. 2,171,353, Aug. 29. App. is described, and a method of utilizing waste heat in hot gases to preheat blast-furnace gas and air by recuperation which comprises transferring heat from the waste gas through refractory walls to air to reduce the gas temp. to a degree non-injurious to metal walls and thereafter reducing the temp. of the gas by the admixture of air, transferring additional heat from the mixt. of waste gas and air to the blast-furnace gas through impervious metal walls.

Metal-heating furnaces, suitable for the heat-treatment of silverware in hydrogen. Carl I. Hayes. Brit. 506,745, June 2, 1939. This corresponds to U. S. 2,101,065 (*C. A.* 32, 901[9]).

Apparatus for the heat-treatment of an assembly of hollow elements, e. g., the cylinders of a multicylinder engine block, by inductive heating coils adapted to be moved into the hollow elements. Howard E. Somes. Brit. 508,027, June 23, 1939.

Furnaces for annealing steel sheets, etc. James C. Woodson (to Lee Wilson Sales Corp.). U. S. 2,171,776-7, Sept. 5. Various structural features.

Furnace and associated apparatus for normalizing and annealing metal sheets such as those of steel. Edward I. Huff (to Huff Equipment Co.). U. S. 2,172,386, Sept. 12. Various structural, mech. and operative details.

Furnace-slag pockets. Irvin C. Johnston. Brit. 506,140, May 23, 1939. The molten slag that collects in the usual slag pocket of, e. g., an open-hearth furnace is drained off into an external receiver connected to the slag pocket through an opening large enough to allow hot gases passing through the pocket to swirl into the receiver, the slag being thus kept in a fluid state until it has passed completely into the receiver, where it solidifies.

Apparatus (with a vibrated riffle box) for recovery of fine particles of metal such as gold from aqueous mixtures. Maurice Constant. U. S. 2,170,069, Aug. 22. Various structural, mech. and operative details.

Refining copper. Herman C. Kenny (to Calumet & Hecla Consolidated Copper Co. of Mich.). U. S. 2,172,009, Sept. 5. A process for refining involves reaction of P with molten Cu in the presence of added Fe or Al in an amt. sufficient to densify the metal but not exceeding 0.1% of the wt. of the Cu, to increase the d. and soundness of the refined product.

Copper powder. Joseph E. Drapeau, Jr. (to Glidden Co.). U. S. 2,170,814, Aug. 29. For producing Cu powder, pieces of substantially pure Cu of large surface area are roasted in an oxidizing atm. to produce a surface oxidation to Cu_2O, the oxidation is stopped while a core of metal remains unoxidized, the Cu_2O is milled and the powd. Cu_2O is sepd. from the Cu, and is reduced to Cu by roasting in a reducing atm. at a temp. below that at which substantial sintering occurs.

Press for extrusion of lead or other metals, as in forming cable sheaths. Geo. T. W. Grieve (to Callender's Cable and Construction Co. Ltd.). U. S. 2,171,062, Aug. 29. Various structural, mech. and operative details.

Joining sheets of aluminum and stainless steel. Richard S. Merritt and Fred Keller (to Aluminum Co. of America). U. S. 2,171,040, Aug. 29. The sheets of different materials are heated together to about 315–480° and subjected to a continuous pressure to produce at least a 5% reduction in the combined thickness of the sheets, and the joined sheets are afterward reheated to about 315–480°. The sheet material thus prepd. may be used for cooking utensils, etc.

Testing materials such as steel rod or wire for vibration fatigue. Alfred V. De Forest (to Research Corp.). U. S. 2,171,303, Aug. 29. Various structural, mech. and operative details.

Decarbonizing metals such as pig iron. Ivar Rennerfelt. U. S. 2,170,158, Aug. 22. For producing low-C iron grains, a charge of small iron granules, obtained by rapidly cooling molten iron in a cooling fluid such as air, water or steam, is heated while stirring the charge by revolution in a combustion zone the atm. of which, contg. CO_2 and CO, is suitably composed for oxidizing only the C but not the Fe of the granules, the heating being sufficient for decarbonization but without melting of the granules.

Graphiting light metals such as aluminum alloys. Heinrich Borofski (50% to Mettmanner Britannia-Warenfabrik W. Seibel). U. S. 2,170,259, Aug. 22. Graphitic C is mixed with a decomposable metal compd. such as Pb acetate and the mixt. is introduced into a melt of a light metal such as an Al alloy and decompn. of the added metal compd. is effected with liberation of metal in close assocn. with the C.

Pickling articles such as those of iron and steel. Richard H. Patch (to E. F. Houghton & Co.). U. S. 2,172,291, Sept. 5. As an inhibitor of metal attack in pickling with a dil. nonoxidizing acid such as H_2SO_4, use is made of a sulfurized cinchona alkaloid such as sulfurized quinoidine and a heterocyclic 5-membered ring compd. contg. both S and N atoms such as 2-mercapto-4 phenylbenzothiazole.

Pickling iron. Walter Heimberger. U. S. 2,171,981, Sept. 5. A method of pickling iron comprises acting on the metal with an aq. soln., heated to at least 50°, which contains free mineral acid in an amt. sufficiently low to permit the metal salts formed to be pptd. by hydrolytic action, an oxidant, and up to about 5% of a salt, the anion of which differs from that of the acid and the cation of which is less noble, in the sense of the electromotive series, than the metal to be treated

Apparatus for surface hardening of metal articles such as dies or tools by heat-treatment and quenching. Albert E. Shorter (to Linde Air Products Co.). U. S. 2,170,876, Aug. 29. Various structural, mech. and operative details.

Hardening refractory metals. Lillian M. Van Note (to Fansteel Metallurgical Corp.). U. S. 2,170,844, Aug. 29. App. is described, and a method of hardening Ta, Cb or their alloys which involves degasifying the metal by heating it at a reduced pressure to 1000–1400°, supplying an atm. of a hardening gas such as air, N or O at a temp. not exceeding 500° until the desired amt. of gas has been taken up, and continuing the heating at a more elevated temp. under a reduced pressure of not more than a few mm. Hg until the absorbed gas has been substantially diffused into the metal body.

Hardening metal articles such as camshafts. Francis S. Denneen and Wm. C. Dunn (to Ohio Crankshaft Co.). U. S. 2,170,130, Aug. 22. A heating and quenching device is used which is provided with an inductor coil adapted to surround a charge to be heated and which is provided on the side adjacent the charge with holes through which a quenching medium is projected with such volume and force as to minimize formation of vapor pockets. Cf. *C. A.* **33**, 8164[6].

Hardening the ends of railway rails. Frank J. Werner (to Inland Steel Co.). U. S. 2,169,776, Aug. 15. App. is described, and a method of hardening the end of a railway rail which is at a temp. below crit. temp. comprising directing and confining a heating medium to the end face portion of the head of the rail from its upper extremity to a point above the lower extremity of the head and the adjacent top portion of the rail to heat the portions of the head above the crit., hardening or transformation temp., and cooling the heated portions of the rail with sufficient rapidity to cause hardening of the portions heated above crit. temp.

Repairing rail ends. Royal E. Frickey (to Welding Service Inc.). U. S. 2,170,859, Aug. 29. A method of repairing rail ends with weld metal involves differentially preheating an end portion of the rail whereby a localized area of the rail surface spaced from the tip of the rail receives more heat than the tip of the rail, applying the weld metal to the end portion of the rail, on the upper surface of the rail ball, to form a layer of weld metal extending longitudinally of the rail, and then utilizing heat to temper a portion of the layer remote from the tip of the rail without tempering the weld metal at the tip of the rail to a comparable degree, thereby avoiding a danger zone of excessive hardness, the heat being residual heat resulting to a substantial degree from the preheating operation.

Cold-drawing metal tubing such as that for hypodermic needles. John W. Ofiutt (to National Tube Co.). U. S. 2,171,595, Sept. 5. Solid wax such as paraffin is used inside the tubing as an internal support during the reducing operation.

Hard tungsten-containing products suitable for tools, etc. Alfred Boecker (to Duradur S. A.). U. S. 2,171,391, Aug. 29. A hard product is prepd. by mixing pulverized W with vanadic acid or titanic acid and with about 8.13% of C but less than the amt. of C theoretically required to form the carbides of the metal components, heating the mixt. to 1500–2000° to form W vanadide or titanide and to carburize the W compd., finely pulverizing the products, making shaped bodies from it, and heating the shaped bodies to 1500–2000°.

Ductile aluminum-coated ferrous metal suitable for drawing and other shaping operations. Marshall G. Whitfield (to Reynolds Metals Co.). U. S. 2,170,361, Aug. 22. A method of rendering ductile an Al-coated ferrous metal, whose Al coating is bonded to its ferrous core by an alloy of Fe and Al, involves subjecting the laminated metal to a plurality of rolling operations at a temp. below that at which there is a material increase in the dispersion of the component metals, which rolling operations successively break the alloy layer into blocks and separate them and then rotate a substantial number of the blocks to embed them in the laminations. Cf. *C. A.* **33**, 8562[1].

Making metal negatives of smooth-surfaced metal objects such as metal patterns for rubber products. Wm. C. Reid (to Metallizing Engineering Co.). U. S. 2,171,503, Sept. 5. A metal object such as a pattern is sprayed with a metal such as Al or bronze while the object is at least at the temp. of incipient adhesion for it and the applied metal, and below the temp. at which inseparable adhesion occurs, at least until the surface is covered with applied metal, thus forming a coherent coating of the applied metal, and this coating is thereafter removed.

Forming products such as copper-coated steel strips. Aaron Simons. U. S. 2,171,132, Aug. 29. Various details of app. and operation.

Forming bright copper surfaces by acid treatment. Walter R. Meyer and Michael F. Dunleavey (to General Elec. Co.). U. S. 2,172,171, Sept. 5. An aq. soln. is used which is formed from concd. H_2SO_4 80–20, concd. HNO_3 20–80, and HCl or a chloride equiv. to concd. HCl 0.1–10 parts; together with chromic acid 5–200 parts.

Extruded products such as pipes or cable sheathing of lead alloy. Brinley Jones (to Goodlass Wall & Lead Industries Ltd.). U. S. 2,171,180, Aug. 29. A Pb alloy is used contg. Te 0.02–0.25% and Cu 0.03–0.1% and is extruded at temps. equal to those customarily employed for extruding ordinary soft Pb to obtain a product which has a fine-grain structure throughout.

Metallic abrasives. John F. Ervin. U. S. 2,171,081, Aug. 29. An abrasive material of high crushing strength and impact resistance, suitable for cutting steel by a blast of the material, comprises an alloy contg. Fe together with C about 3, Mn 0.5, Si 1.5, S 0.1, P 0.4, Cr 0.25–3.0 and Mo 0.1–0.6%. U. S. 2,171,082 relates to otherwise similar alloys contg. Cr 0.1–1.5 and Ni 0.1–3.0%. U. S. 2,171,083 relates to a like alloy contg., instead of the Mo, up to 0.06% of V. Cf. *C. A.* **33**, 3325[4].

Improving the texture of rolled articles such as rails. Franz Bartscherer. U. S. 2,171,074, Aug. 29. The articles are initially formed with local protrusions on at least 2 opposite sides of an ingot which are to have a crystallite arrangement substantially parallel to the surface of the finished article, the protrusions being

spaced from the end of the ingot to facilitate feeding it to the rollers, and the ingot is rolled to reduce the local protrusions and produce the parallel crystallite arrangement.

Roller-rail constructions for use in furnaces for heat-treating metal articles. Henry H. Harris. U. S. 2,172,376-7-8-9-80-1, Sept. 12. Various structural, mech. and operative details.

Metal-containing compositions. Tool Metal Manufacturing Co. Ltd. Brit. 506,964, June 7, 1939. A compn. for cutting-tools comprises a sintered mixt. of Al_2O_3 and 20–40% of a metal, e. g., Fe, Ni, Co. The Fe may contain 0.1–5% of Cr, V, Ti, Co or Ni. The compn. may be of Al_2O_3 and metal oxide, the latter being converted to metal by sintering in a reducing atm.

Metal half-tone screens. Edward O. Norris (to Edward O. Norris, Inc.). U. S. 2,171,276, Aug. 29. Use is made of a thin perforated sheet of metal such as Cu mounted in a rigid frame under tension and having a surface substantially nonreflective to light.

Gold films. Charles S. Gibson. U. S. 2,171,086, Aug. 29. See Brit. 497,240 (*C. A.* **33**, 3753[3]).

Blow-pipe apparatus for removing surface defects from metallic bodies by oxygen jets. James H. Bucknam (to the Linde Air Products Co.). Brit. 507,259, June 13, 1939.

Blowpipe apparatus for removing a surface layer from steel slabs, billets, blooms, etc. James H. Bucknam (to the Linde Air Products Co.). Brit. 507,279, June 13, 1939.

Removing scale from chromium alloy steels. Stephen F. Urban. U. S. 2,172,041, Sept. 5. A pickling soln. for removing scale from chrome steels, chrome-Ni and the like, contg. at least 12% Cr, contains water together with HF 0.5–10%, chromic acid 5–20% and H_2SO_4 1–10% by vol.

Grinding apparatus suitable for smoothing steel rods, etc. Sylvester G. Richardson (to Norton Co.). U. S. 2,171,892, Sept. 5. Various structural, mech. and operative details.

Light-weight construction steel. Byramji D. Saklatwalla. U. S. 2,171,375, Aug. 29. A low-C alloy steel of high phys. properties may contain C 0.01–0.25, Si 0.6–1.5, Cu 0.25–0.6, Ni 0.5–1.25, P 0.1–0.25, Mn less than 0.6 and S under 0.1%, the balance being substantially all Fe and the alloy steel being free from any such amt. of Cr as would materially modify its properties (the Cr present being less than 0.25%); it has a tensile strength in the as-rolled condition of about 65,000 to 80,000 lb. per sq. in., the yield point being over about 70% of the tensile strength, and further characterized by a ductility and deformability at least equal to that of carbon steel of corresponding strength, together with good capability of being welded by the ordinary commercial processes of welding.

Alloy steel. Geo. R. Rich (to Rich Mfg. Co.). U. S. 2,170,267, Aug. 22. An alloy steel of high tensile strength suitable for the manuf. of motor-valve parts contains C about 0.32, Cr 5.5, Si 3.25, Ni 2.42, Mn 0.8, S 0.025 and P 0.025%, the remainder being Fe. U. S. 2,170,268 relates to an alloy of Fe with C 0.25, Cr 6.25, Si 3.25, Ni 1.9, Mn 1.0, and S and P 0.025% each.

Stainless steels. Albert L. Kaye, Robert S. Williams and John C. Wulff (to Chemical Foundation, Inc.). U. S. 2,172,388, Sept. 12. A method of increasing the resistance of stainless steels to electrochem. corrosion in saline media involves preforming on the surface of the metal, prior to service use, a continuous, insol. film of a metal chloride derived (as by the action of a $FeCl_3$ and HCl soln.) from a metal such as Ag or Mo included in the steel. Cf. *C. A.* **33**, 6222[1].

Coloring stainless steel. Clements Batcheller (to Allegheny Ludlum Steel Corp.). U. S. 2,172,353, Sept. 12. A method of coloring the surface of an alloy steel contg. 7% or more of Cr involves subjecting it to the action of a soln. contg. H_2SO_4 and an oxidizing agent and etching-inhibitor which may be vanadic or metavanadic acid or one of their NH_4, K or Na salts, to form a coherent and adherent color film (the H_2SO_4 being of sufficient concn. that if used alone it would dissolve the steel).

Alloys such as ferro-alloys and "inoxidizable" steels. Rene Perrin (to Société d'électrochimie, d'électrométallurgie et des aciéries électriques d'Ugine). U. S. 2,169,741, Aug. 15. In making an alloy such as a ferro-Cr alloy by the reaction of an O compd. of the alloy metal, such as a Cr ore, with a Si reducing agent such as ferro-Si and lime, a portion of the reagents is charged into a mixing receptacle in the molten state and the remainder in the solid state, and the reagents are violently mixed by pouring them back and forth from one chamber to another to initiate and maintain the reaction (the portion of the reagents added in the solid state being sufficiently small as to produce a molten fluid slag).

Hard metal alloys for tools such as those for machining. Paul Schwarzkopf (to American Cutting Alloys, Inc.). U. S. 2,170,432, Aug. 22. A cemented hard metal is used, sintered by heat-treatment and comprising an auxiliary metal of the Fe group such as Ni, Co or Cr 3–22% together with 2 carbides of elements from the 3rd, 4th, 5th or 6th groups of the periodic system such as carbides of Ti and Zr contg. together substantially more than 2.6% C and being present in finely divided form and proportions suitable to yield mixed crystals of approx. greatest hardness on heat-treatment. U. S. 2,170,433 relates to details of prepg. products of generally similar character.

Alloy suitable for electrical contacts. Hans H. Schwarzkopf (to N. V. Molybdenum Co.). U. S. 2,170,431, Aug. 22. An alloy suitable for elec. contacts and for use as a prealloy (suitable together with W, Mo or Ta) for elec. material may contain Cu 94.7, Ag 4, Cd 1 and B 0.3%, the proportions being variable.

Cast bearings of light metal alloys. Carl Steiner (to American Light Corp.). U. S. 2,171,229, Aug. 29. A supporting shell is cast, formed of an Al alloy having great strength such as an alloy contg. Al together with Si 20–22% and within this is cast an inner shell of a light metal alloy having good antifriction properties such as an alloy contg. Al and Sb or Mg so that the alloys are in intimate contact while both are at least in a semiplastic condition.

Bearings of aluminum alloys, suitable for airplane engines. Hans Steudel (to Junkers Flugzeug- und Motorenwerke A.-G.). U. S. 2,170,039, Aug. 22. A process of bearing manuf. involves kneading a material comprising essentially Al as a base and at least one metal of the Fe group, the compn. being hypereutectic and composed of crystals of an intermetallic compd. of Al and an Fe group metal distributed in a matrix of a softer eutectic ground mass, to cause the crystals to assume a smaller, more rounded form and to adhere firmly to the ground mass. The bearing metal may, e. g., contain Al 92–95% with Ni, Co, Cr or Fe, Cu, Zn, Mg, Mo, etc.

Permanent magnets of copper-cobalt-nickel alloys. Dannohl and Hans Neumann (to Siemens & Halske A.-G.). U. S. 2,170,047, Aug. 22. Permanent magnets are formed of alloys contg. Co 15–65, Ni 15–35 and Cu 20–65% and are characterized by a coercive force above 400 oersteds and a remanence above 1000 gausses.

Copper-magnesium-silver alloys. Franz R. Hensel and Earl J. Larsen (to P. R. Mallory & Co.). U. S. 2,171,697, Sept. 5. Alloys which are suitable for elec. contacts, etc., contain Cu together with Mg 0.05–3 and Ag 0.05–15%.

Corrosion-resistant ferrous alloys. Herbert H. Uhlig (to Chemical Foundation, Inc.). U. S. 2,172,421, Sept. 12. A method of treating articles composed of ferrous alloys, contg. components such as Cr and Ni, involves subjecting the articles to the action of a highly active metal solvent (which may also contain $TiCl_4$) having a dissolving action on steel equiv. to that of an aq. soln. contg. about 50% of a mixt. of H_2SO_4 and HCl, for a time sufficient to effect the removal of about 0.000- in. of surface metal to insure a substantially macroscopically smooth surface free from pit-engendering mech. imperfections. U. S. 2,172,423 relates to a method of increasing the resistance of Ni- or Mn-contg. stainless steels to pit corrosion which in-

wlves providing them with an adherent and compacted surface film of Ag and subsequently bringing the Ag into contact with a reagent to form a continuous film of an insol. Ag compd.

Corrosion-resistant ferrous alloys. John C. Wulff (to Chemical Foundation, Inc.). U. S. 2,172,427, Sept. 12. To render Cr-contg. ferrous alloys and steels (such as a stainless steel of the 18 Cr, 8 Ni type) substantially immune to pit corrosion, the cold deformed alloy while in a vacuum is heated to a temp. (suitably about 1000–1200°) which is above the carbide-forming temp., to eliminate surface imperfections which form potential loci for the initiation of pit corrosion. U. S. 2,172,428 (John C. Wulff and Herbert H. Uhlig; to same assignee) relates to reducing the pit-corrosion susceptibility of articles composed of passive ferrous alloys which involves subjecting the articles to a low-temp. annealing under conditions which are effective substantially to reduce nonmetallic inclusions, and subsequently treating with a highly active metal solvent contg. over 50% of a mixt. of H_2SO_4 and HCl to dissolve sufficient surface metal substantially to eliminate loci of pit corrosion.

Iron alloys suitable for electric heating resistances. John D. Gat. U. S. 2,172,023, Sept. 5. Ductile, heat-resistant alloys are formed contg. Fe together with not more than 0.16% C, not less than 6% of Al, and a sufficient amt. of Ti, Mo, Ta or Cb to prevent any substantial presence of carbides at the grain boundaries of the alloy (the quantity of such ingredients not being greater than 6 times the amt. of C nor over 1%), and a total of Mn, S, P and Si not exceeding 2%.

Stabilizing silicon alloys. Ernest F. Doom (to Electro Metallurgical Co.). U. S. 2,171,108, Aug. 29. For prepg. a stable unbonded finely comminuted Si alloy contg. more than 35% Si, such as a ferro-Si alloy for use as a constituent of alk. coating compds., a thin superficial protective oxide coating is formed on the alloy by heating it to 300–1000° for a time too short to cause the oxidation of a major part of the alloy.

Alloys for casting dentures, etc. Cornell J. Grossman. U. S. 2,171,744, Sept. 5. Co is used together with B 0.5–15, Ti 1–30 and Cr 3–45%. Cf. *C. A.* **33**, 8166[1].

Spindle blades for spinning and twisting machines. Harry Mitchell (to Whitin Machine Works). U. S. 2,170,727, Aug. 22. A spindle blade comprises a bar of air-hardened Mo alloy steel of a substantially uniform initial hardness, the blade being formed from the bar entirely by grinding operations and the initial hardness of the steel being substantially maintained during the production of the blade, the steel bar used being initially air-hardened to approx. 60 on the Rockwell C scale and contg. approx. C 0.5, Mn 0.5, Cr 1.0, Ni 1.5 and Mo 0.5%.

Treating aluminum surfaces preparatory to painting, etc. Walter R. Kappes (to Aluminum Co. of America). U. S. 2,171,546, Sept. 5. The surface is treated with an aq. alkali metal carbonate-chromate soln. to produce a substantial oxide coating and this coating is then removed with HNO_3 or chromic acid.

Protective paint coatings on aluminum and its alloys. Junius D. Edwards and Ralph L. Mason (to Aluminum Co. of America). U. S. 2,171,545, Sept. 5. The metal surface is etched with a HCl soln. in which Mn, Fe, Cu, Ni or Co is dissolved, the etched surface is treated with a chromic acid soln., and a paint film is thereafter applied.

Welding materials such as cast iron. Glenn V. Ireland. U. S. 2,171,366, Aug. 29. In welding, with deposition of a single coat of soft ferrous metal on the parts to be welded, without preheating these parts, use is made of a welding electrode which may comprise a rod of ferrous material of low C content carrying a coating contg. a flux such as borax as its principal ingredient (but not exceeding 50%), a ferrous compn. such as Fe oxide, $NaHCO_3$, a deoxidizing agent such as ferro Si or Al, and a binder such as Na silicate.

Welding metal parts such as those of ferrous metals. Thomas S. Gaylord. U. S. 2,170,019, Aug. 22. A metallic weld strip such as one of a Cu alloy having a coating including a corrosion-resistant metal such as Sn, Cr or Ni is melted to form a seam at the juncture of the parts to be welded, the heat for melting the strip at least partially destroying the protective layer of metal along the margins of the seam while the molten corrosion-resistant metal coating of the strip flows to the margins of the seam and into the regions of deteriorated protective layer. App. is described.

Welding magnesium and its alloys. Josef M. Michel (to Magnesium Development Corp.). U. S. 2,171,011, Aug. 29. A flux is used contg. at least one inorg. halide which is nonvolatile at temps. at which welding is carried out, such as KF and LiBr, together with phosphoric, oxalic or boric acid or an acid-reacting salt of such an acid capable of reacting with the halide to cause volatilization of the halogen hydracid derived from the halide, with formation of nongaseous reaction products having no corrosive action upon the metal to be welded. MnO_2, etc., also may be used.

Butt welding thin sheet material such as alloy steels. James E. Fay and Fo Reed (to American Rolling Mill Co.). U. S. 2,172,080-1, Sept. 5. Various details of app. and operation.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Researches on organic chemistry in India, 1896–1923. P. C. Mitter. *Proc. Natl. Inst. Sci. India* **5**, 211–36 (1939). G. G.

Low-molecular polymerization of dienes and trienes. Ernest Harold Farmer. *Trans. Faraday Soc.* **35**, 1034–40 (1939).—The types of structures which are formed by low-mol. polymerization of conjugated and unconjugated dienes and trienes are reviewed. All, save α-phenylbutadiene, which have been so far examd. yield a cyclohexenic dimeric form. Some sort of open-chain dimeric structure but no appreciable amt. of tetramer. Thermal and acid-catalyzed dimerization and trimerization processes are discussed. E. g., the acid-catalyzed 2,3-dimethylbutadiene forms dimeric (29%), trimeric (19.5%), tetrameric (18.4%) and pentameric (15%) fractions which can be easily isolated, leaving a viscous residue which is almost entirely hexamer. The pentadiene $CH_2:CHCH_2CH:CH_2$, is discussed as an example of thermal polymerization of unconjugated dienes. Victor R. Deitz

Dimerization.—Heavy metal sulfides as catalysts for the polymerization of olefin hydrocarbons. E. H. Ingold and A. Wassermann. *Trans. Faraday Soc.* **35**, 1022–4, 1052–3(1939).—Dimerization of cyclopentadiene in paraffin soln. at atm. pressure and 155° was found to take place in the presence of CuS, Cu_2S, Ag_2S, HgS, Tl_2S, SnS, PbS, Bi_2S_3, FeS, $KFeS_2$, $FeCuS_2$, NiS; neg. results occurred with SrS, ZnS, CdS, SnS_2, As_2S_3, MoS_2 and FeS_2. The dimerization of trimethylethylene was found to take place most efficiently with CuS prepd. from $CuSO_4$ and [illegible] to 90%. It is suggested that the catalysis is connected with an oxidation-reduction process—part of the starting substance is converted into CO_2 and H_2O, while the Cu-SO_4 is reduced to SO_2 and Cu or Cu_2O—a peroxidic intermediate compd. taking part. Victor R. Deitz

Dimerization reactions of unsaturated hydrocarbons. Ernst Bergmann. *Trans. Faraday Soc.* **35**, 1025–34, 1052–3(1939); cf. *C. A.* **33**, 5698.—Dimerization of olefins yields cyclobutane derivs. only upon irradiation with

ultraviolet light. "Migratory or catalytic" dimerization of olefins proceeds generally by migration of an H atom. The exptl. evidence (68 references) in favor of these 2 rules is presented. The dimerization of cinnamic acid is an example of the 1st rule, while illustrations of the 2nd are to be found in styrene, α-methylstyrene, dimerization of acetylenes and triphenylallene. The dienes yield products which do not directly correspond to the migration scheme. Victor R. Deitz

Dimerization of petroleum hydrocarbons. W. J. Sparks, K. Rosen and Per K. Frolich. *Trans. Faraday Soc.* **35**, 1047–52, 1053–4(1939).—It has been shown that most of the known products resulting from dimerization of aliphatic unsatd. hydrocarbons can be explained by the 1,3-rearrangement of H. However, all the possible reaction products that could be written according to this mechanism have not been recorded in the literature and may not necessarily be formed. The dimerization of isobutene, the codimers of isobutene and butenes and the polymerization of the *n*-butenes are reviewed. It is shown that the unreliability of the methods used to identify the isomers resulting from the cross-polymerization of isobutene and butene based on the b. p. and *n* may well lead to results which confuse arguments as to mechanism of the reactions. Victor R. Deitz

Butadiene polymers; elucidation of structure by ozonolysis. R. Hill, J. R. Lewis and J. L. Simonsen *Trans. Faraday Soc.* **35**, 1067–73, 1079–89(1939).—Ozonolysis of a butadiene polymer suspended in $CHCl_3$ gave succinic acid, butane-1,2,4-tricarboxylic acid and resinous acids. These results indicate that, in aq. emulsion, butadiene polymerizes by all 3 of the possible additive mechanisms, viz., 1,4-addn., 1,2-addn. and conjoint 1,2- and 1,4-addn., but a quant. discrimination between the various mechanisms is not possible. It is suggested that chain initiation is due to the formation of a "dimer complex" which under normal conditions yields vinyl-3-cyclohexene. Victor R. Deitz

Butadiene copolymers: elucidation of structure by ozonolysis. R. Hill, J. R. Lewis and J. L. Simonsen. *Trans. Faraday Soc.* **35**, 1073–9, 1079–85(1939).—Isolation of 2-methylbutane-1,2,4-tricarboxylic acid, from the ozonolysis of a product obtained by polymerizing equimol. quantities of butadiene and Me methacrylate together in aq. emulsion, establishes a possible copolymer structure. More than half of the essentially linear polymer is composed of alternate units of butadiene and Me methacrylate. In this case butadiene polymerizes in the main by 1,4-addn. It is suggested that the mols. of butadiene and Me methacrylate form a Diels-Alder complex. Chain initiation may then involve an activated complex or possibly the Diels-Alder thermal addn. proceeding in an environment favoring chain growth. The differences between the copolymer and the butadiene polymer are correlated with this theory. Victor R. Deitz

Combination of saturated hydrocarbons and olefins. Some problems associated with olefin-isoparaffin addition reactions. S. F. Birch and A. E. Dunstan. *Trans. Faraday Soc.* **35**, 1013–21(1939); cf. *C. A.* **33**, 8381⁶.—The addn. of olefins to isoparaffins in the presence of H_2SO_4 at a low temp. to give higher paraffins is discussed. Of the paraffins examd. isobutane, isopentane and isohexane (2-methylpentane) react readily, but isooctane (2,2,4-trimethylpentane) fails to do so. The olefins propene, 1-butene and 2-butene, isobutene and its di- and trimerides, the butene-isobutene codimer and trimethylethylene all react smoothly and give excellent yields of isoparaffinic products. The action of the H_2SO_4 is catalytic but in operation its activity falls off, at first slowly and finally rapidly. This is accompanied by progressive darkening of the acid, the vol. of which increases. On dilu. of the acid with H_2O there seps. a highly unsatd. oil. Some possible mechanisms are discussed; that used by Whitmore (cf. *C. A.* **28**, 1324⁹) for the polymerization of isobutene; also the mechanism used by Ingold, Raisin and Wilson (cf. *C. A.* **31**, 653⁸, 666⁷) for exchange reactions between D_2SO_4 and certain paraffinoid hydrocarbons. Victor R. Deitz

The isomerization of carotenes. III. Reconsideration of the change β-carotene to pseudo-α-carotene. Gertrude P. Carter and Albert E. Gillam. *Biochem. J.* **33**, 1325–31(1939); cf. *C. A.* **32**, 1707¹.—The suggestion of Zechmeister and Tuzson (*C. A.* **32**, 9120²) that the isomerization of β-carotene was spontaneous and not due to adsorption was confirmed experimentally. The reverse change of pseudo-α-carotene to β-carotene was found to be more rapid. To reduce the tendency of carotene to isomerize, the solns. should be stored at 0° and concn. of the solns. should only be carried out at low temp. When partial isomerization occurred, one adsorption on alumina just before use gives pure β-carotene. E. W. Scott

Fluorocarbons. The reaction of fluorine with carbon. J. H. Simons and L. P. Block. *J. Am. Chem. Soc.* **61**, 2962–6(1939).—A method for the prepn. of fluorocarbons by the continuous reaction between F and C without explosions is described. Compds. corresponding in mol. wt. to C_3F_8, 2 isomers of C_4H_{10}, decafluorocyclopentane, dodecafluorocyclohexane, and C_7F_{14} (probably cyclic) were prepd. and are described. A. B. Garrett

Chloro compounds obtained by means of aqueous sodium hypochlorite. A. Leulier and R. Cohen. *J. pharm. chim.* **29**, 245–51(1939).—Three compds. are described: dichlorourotropine (I), dichloropiperazine (II) and chloroantipyrine (III). Prepn. (I): To 5 g. $(CH_2)_6N_4$ in 40 cc. H_2O add 8.40 g. $KHCO_3$ and 45 cc. NaOCl (72 g. active Cl per l.); after 5 min. filter the ppt. rapidly, wash with H_2O, 0.02 *N* NaOH, alc. and Et_2O. Yield 77–80%, white scales m. 77° (Maquenne block), decompg. 140°, explosive when heated in a flame. Soly. in 100 cc. H_2O (by Cl detn.) 0.206; Et_2O 2.036; alc. 2.148; $CHCl_3$ 2.282 g. Aq. and alc. solns. lose all Cl in 4 days; $CHCl_3$ in 20 days. The prepn. of II and III is similar, except that more NaOCl is used. Yields of II and III are, resp., 80% and 91.17%. II, m. 74° without decompn., is more stable than I, but entirely volatile in the air. III, recrystd. from acetone and petr. ether, m. 131–2°, not 126–7° as obtained before. S. Waldbott

Organic catalysts for the cleavage of carbon monoxide from formamide. II. Catalysts with alcoholic hydroxyl as the active group. Terje Enkvist, Hella Merikoski and Paavo Tikkanen. *Ber.* **72B**, 1717–23(1939); cf. *C. A.* **33**, 7275⁶.—Complex substances with alc. HO have been tested as to catalytic ability to cleave formamide (I) into CO and NH_3, in the hope of finding in this way by activation according to Langenbeck new catalysts also effective in the synthesis of I. The same method was employed as in part I except that the measurement of the CO was complemented by titration of the liberated NH_3 which sublimed in the CO_2 stream as NH_4 carbamate. Results are given for NaOMe, benzyl and cinnamyl alcs., choline, choline chloride, glycolic acid as Na salt, Et ester, amide, anilide, α- and β-naphthylamides and toluidide, *p*-glycylamino-1-nitrobenzene (m. 183–4°, prepd. from glycolic acid and *m*-nitroaniline at 140°), ethylene and propylene glycols, thiodiglycol, glycerol α-Et and α-Ph ethers, diethanolamine, glycerol, erythritol, pentaerythritol, quercitol, *d*-mannitol, dulcitol, sorbitol, inositol, triethanolamine, α-Me *d*-glucoside, helicin, amygdalin, salicin, sucrose and glycerol diformin. The following showed very little or no activity: undecyl, *sec*-octyl and phenethyl alcs., Ph_2COH, $C_6H_{11}OH$, $C_6H_{11}CH_2OH$, Ph_2CH_2OH, furfuryl, $Et_2NCHMeCH_2OH$, $ClCH_2CH(OH)CH_2OPh$, $AcNH_2$, Et, iso-Am, allyl and pinacolyl alcs., pinacol, Na glycerophosphate, glucose, glucosamine-HCl, fructose, galactose, lactose, maltose, starch, cellulose. In the absence of Na_2CO_3 the alc. HO in no case exerted a detectable catalytic effect on the cleavage of CO. With increasing amts. of Na_2CO_3 the evolution of CO increased in the 1st half hr. until it reached a max. with about 0.5 equiv. Na_2CO_3 per equiv. of the org. catalyst. With only 0.5 equiv. the CO evolution in the later stages of the reaction decreased rapidly at 140° but at 120° it increased somewhat. With more Na_2CO_3 (e. g., 1 equiv.) the decrease in velocity in the later stages was much smaller, and an evolution which had already become slow could be revived by adding more Na_2CO_3. Under

conditions otherwise the same, the reaction velocity varied approx. proportionately with the amt. of org. catalyst. Water even in small amt. almost completely inhibited the catalysis. The velocity of the stream of CO_2 had little influence on the velocity of CO evolution. Apparently about 120° is a temp. threshold below which there is practically no reaction; between 140° and 160°, on the other hand, the van't Hoff rule (2- to 3-fold increase in velocity per 10°) seemed to hold. Since the catalytic effect is exerted only in the presence of Na_2CO_3 the reaction probably proceeds through org. anions; the mechanism

$$HCONH_2 \overset{Na_2CO_3}{\rightleftharpoons} [HCONH]^- + H^+;\ [HCONH] + ROH \rightleftarrows [CO_2R]^- + NH_3;\ [CO_2R] \rightleftarrows [OR]^- + CO;\ [OR]^- + H^+ \rightarrow ROH,$$

is provisionally suggested. Results to date: Substances with primary (pentaerythritol) or secondary (inositol, quercitol) alc. HO can, but only in the presence of alkali, catalyze the cleavage of CO from I, while tertiary alcs. (Ph_3COH, pinacol) do not. Ordinary aliphatic (undecyl, *sec*-octyl) or alicyclic (cyclohexanol) monohydric alcs. do not catalyze the reaction. The following substituents show a weak catalytic action: certain aromatic rings (cinnamyl and benzyl alcs.), amino N (di- and triethanolamines, choline, choline chloride), and carboxyl as the Na salt (Na glycolate). More strongly catalytic are carbethoxy and amide groups, especially anilide, toluidide, naphthylamide (glycolic acid derivs.). Several alc. HO groups in the same mol. activate each other, less in dihydric (glycol and derivs.), more in tri- to hexahydric alcs. (glycerol, erythritol, quercitol, pentaerythritol, mannitol, dulcitol, sorbitol, inositol, all of which have about the same catalytic effect per HO group). The aldehyde and keto groups have a strong inhibiting action; glucose, fructose, galactose, lactose and maltose show no catalytic action, helicin only a little. Ether O, including the bridge O of glucosides and disaccharides, seems to be indifferent or activating (glycerol Et and Ph ethers, α-Me *d*-glucoside, salicin and especially sucrose are strongly catalytic). Ordinary phenol (0.001 mol.) and, even more, pyrogallol (0.00033 mol.) with 0.0005 equiv. Na_2CO_3 and 0.20 cc. I at 140° produce a vigorous evolution of gas (12.6 and 37.2 cc., resp., in 30 min.). C. A. R.

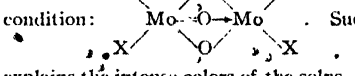
Some amidines and amide oximes with trypanocidal activity. I. D. Lamb and A. C. White. *J. Chem. Soc.* **1939**, 1253–7.—The amide oximes were prepd. by mixing the dinitrile (0.025 mole) in 200 cc. EtOH with 7 g. $NH_2OH.HCl$, adding 2.3 g. Na in 60 cc. EtOH and shaking at 60° for 20–30 hrs. *Dicarboxamide oximes: pentane-1,5-*, m. 142–4° (*di-HCl salt*, m. 150–5°); *heptane-1,7-*, m. 156°; *nonane-1,9-*, m. 167°; *decane-1,10-*, m. 184–6° (decompn.) (*di-HCl salt*, m. 149–58°; *di-Ac deriv.*, m. 129° and is deacetylated by cold dil. HCl); *undecane-1,11-*, m. 166° (*di-HCl salt*, m. 178°) (by-products in this prepn. include *undecane-1-carboxamide-11-carboxamide oxime*, m. 157–8°, whose *HCl salt* m. 144° and the *11-carbonitrile*, m. 87–8°; *HCl salt*, m. 84°); *tridecane-1,13-*, m. 170° (*di-HCl salt*, m. 158–60°), (the *1-carbonitrile deriv.* m. 98°; *HCl salt*, m. 96°); *biphenyl-4,4'-*, m. 245° (decompn.) (*di-HCl salt*, m. 290° (decompn.)); *diphenylmethane-4,4'-*, m. 215° (*di-HCl salt*, decomp. 220°); *bibenzyl-4,4'-*, decomp. about 243° (*di-HCl salt*, pale yellow prisms); *stilbene-4,4'-*, m. above 320° (decompn.), was prepd. from *4,4'-dicyanostilbene*, orange, m. 278° (*di-HCl salt*, chars about 300°). The following *dicarboxamidines* were prepd. from the nitriles by way of the imido esters: *decane-1,4-* (*di-HCl salt*, m. 227–8° (decompn.)); a by-product of the action of KCN on dibromodecane is *decane-1-carbonitrile-10-carboxamide*, m. 87°. *Decanebis-(N,N'-diphenylcarboxamidine)*, m. 163–5°; *N-cyclohexyl analog*, m. 122° (*di-HCl salt*, m. 273°). *Undecane-1-carbonitrile-11-carboxamide*, m. 101°. *Tridecane-1-carbonitrile-13-carboxamide*, m. 103–4°; *tridecane-1-carboxamide-13-carboxamidine-HCl*, m. 164–5°; *tridecane-1,13-dicarboxamide*, m. 176°. *Tetradecanemonocarboxamidine-HCl*, m. 138°; *picrate*, m. 166°. Di-Et decanedicarboxyimidate ether and $C_2H_4(NH_2)_2$ heated 8 hrs. at 70°, give *1,10-bis(4,5-dihydro-2-glyoxalinyl)decane*, m. 181°; *picrate*, m. 223–4°; *HCl salt*, m. 183°. The trypanocidal activity of these compds. has been investigated and data for several are given. C. J. West

Esters of methanesulfonic acid in the sugar group. B. Helferich, H. Dressler and R. Griebel. *J. prakt. Chem.* **153**, 285–99(1939).—Details are given of the prepn. from glucose of tetraacetyl-6-mesyl-β-*d*-glucose (29% yield), of tetraacetyl-β-*d*-glucose 6-iodohydrin (96% yield) and of the α-isomer (I). I (10 g.) in 100 cc. 70% AcOH at 80–5°, treated gradually with 25 g. of Zn dust, gives 35% of *tetraacetyl-α-d-isorhamnose*, m. 119.5° (all mps. cor.), $[\alpha]_D^{19}$ 123.8° ($CHCl_3$); shaking with AcOH-HBr gives 92% of acetobromo-*d*-isorhamnose, m. 143.5–4°. Diacetoneglucose and mesyl chloride in C_5H_5N at 0°, allowed to stand 15 hrs., give 88% of *1,2,5,6-diacetone-3-mesylglucofuranose* (II), m. 83–4°, which with H_2SO_4 in 50% MeOH (refluxing 100 min.) gives 70% of *3-mesyl-d-glucose*, m. 133–4°, $[\alpha]_D^{19}$ 77° (H_2O), changing to 66.9° in 2 days; Ac_2O-AcONa gives 75% of *tetraacetyl-3-mesyl-β-d-glucose* (IIA), m. 169–70°, $[\alpha]_D^{19}$ 1.5° ($CHCl_3$); AcOH-HBr with a little Ac_2O, shaken 2 hrs. at room temp., gives *3-mesyl-2,4,6-triacetobromo-α-d-glucose* (III), $[\alpha]_D^{19}$ 160° ($CHCl_3$), which could not be crystd. II and AcOH-HBr give 25% of *3-mesyl-2,6-diacetobromo-α-d-glucose* (IV), m. 136–7°, $[\alpha]_D^{19}$ 170° ($CHCl_3$). III and Ag_2CO_3 in MeOH, shaken for 10 hrs., give 81% of *triacetyl-3-mesyl-β-methyl-d-glucoside*, m. 128–8.5°, $[\alpha]_D^{19}$ −21.7° ($CHCl_3$), and IV gives 89% of the *2,6-di-Ac analog*, m. 105°, $[\alpha]_D^{19}$ −56.8° ($CHCl_3$). IV in Me_2CO and PhOK in H_2O give 33% of the *2,6-diacetyl-3-mesyl-β-phenyl-d-glucoside* (V), m. 134.5–5°, $[\alpha]_D^{19}$ −56.6° ($CHCl_3$); *2,4,6-tri-Ac analog* (VI), m. 154–4.5°, $[\alpha]_D^{19}$ −27° ($CHCl_3$), 90% yield. V in $CHCl_3$ and 1% MeONa in MeOH, kept 3 hrs. at −20° and 15 min. at room temp., give 80% of *3-mesyl-β-phenyl-d-glucoside*, m. 175°, $[\alpha]_D^{19}$ −28.2° (C_5H_5N); Ac_2O in C_5H_5N gives VI, as does melting IIA, PhOH and *p*-$MeC_6H_4SO_3H$. Warming 15 g. of II with 12 cc. H_2O and 30 cc. AcOH for 2.5 hrs. at 50–3° gives 12.5 g. of *1,2-acetone-3-mesylglucofuranose*, $[\alpha]_D^{19}$ −20.6° (H_2O); *5,6-di-Ac deriv.*, m. 136–6.5°, $[\alpha]_D^{19}$ −2.3° ($CHCl_3$); AcOH-HBr gives 50% of *3-mesyl-2,5,6-triacetobromo-α-d-glucofuranose*, m. 125–3.5°, $[\alpha]_D^{19}$ 191.5° ($CHCl_3$). Diacetonegalactose and mesyl chloride in C_5H_5N give a good yield of *1,2,3,4-diacetone-6-mesylgalactopyranose*, m. 122°, $[\alpha]_D^{19}$ −62° ($CHCl_3$); NaI in Me_2CO at 100° gives diacetonegalactose 6-iodohydrin. C. J. West

Structure of the diacetonedulcitols. Raymond M. Hann, W. Dayton Maclay and C. S. Hudson. *J. Am. Chem. Soc.* **61**, 2432–42(1939).—Pizzarello and Freudenberg (*C. A.* **33**, 3338⁷) have proposed the structure 3,4,5,6-diacetonedulcitol for Fischer's α-deriv. (I) (*C. A.* **9**, 1183⁵) and the 1,2,3,4-isomer for the β-deriv. (II); they pointed out that the structures are enantiomorphous and emphasized the ready sepn. of I and II by fractional crystn.; this fact and the differences in their phys. properties and those of their derivs. seem to exclude this idea and prove that they are structural isomers. The prepn. of I and II is apparently affected by small variations in exptl. conditions, possibly due to cyclic acetal rearrangement of the sensitive I. Finely powd. dulcitol (III) (50 g.) in 975 cc. Me_2CO contg. 24.2 g. of dry HCl, shaken for 24 hrs. at 20°, gives 34% of I; removal of the HCl with basic Pb carbonate and concn. give addnl. I (total yield 48%); the mother liquors yield 45% of crude II. I (from 95% EtOH in 90% yield) m. 144–5° (all m. ps. cor.), n_α 1.503, n_β 1.507, n_γ 1.548; the birefringence is strong and the polarization colors are brilliant. II (from 5 parts Me_2CO and 10 parts petr. ether) m. 111°, n_α 1.488, n_β 1.510, n_γ 1.518; the birefringence is strong and the polarization colors are of the 1st order; the optic sign is neg., $2E = 30°$ (approx.). These properties preclude the possibility that I and II are enantiomorphous forms. On oxidation of I in H_2O with 8 moles of HIO_4 at 20° for 0.25, 0.5, 1, 4 and 22 hrs., 1.83, 2.77, 3.68, 5 and 5.17 moles of oxidant were consumed; thus the Me_2C groups were hydrolyzed and the III thus liberated was completely oxidized (theory, 5 moles of HIO_4). With $NaIO_4$ only 0.35 mole of oxidant was consumed in 20 hrs. at 20°; the acidity is so low that hydrolysis is greatly retarded and the oxidant appears to

be without action on I itself; $Pb(OAc)_4$ also appears to be without action on unhydrolyzed I. With II 0.94 mole and 5.8 moles of HIO_4 were consumed after 1 and 50 hrs. at 20°; no $NaIO_4$ was consumed at the end of 4 days at 20 and only 0.03 mole of $Pb(OAc)_4$ after 20 hrs., indicating that II is considerably more resistant to hydrolysis than I. The results also show that there is no glycol grouping present in either I or II and therefore the 2 HO groups present in each are not attached to adjacent C atoms; II and Ac_2O in C_5H_5N give a quant. yield of the *1,6-di-Ac deriv.* (IV), m. 134°; the relative insoly. of IV in the acetylating medium affords an easy method for the sepn. of I and II. II and *p*-$MeC_6H_4SO_2Cl$ in C_5H_5N give 96% of the *1,6-ditosyl deriv.* (V), m. 165–6°; *1,6-ditrityl deriv.*, decomp. 233–4°. Heating V with 3 moles of NaI in Me_2CO for 2 hrs. at 100° gives a nearly quant. yield of the *1,6-di-I deriv.*, m. 108–9°. The di-Bz deriv. (VI) of II, m. 183–4° (Fischer designated this as the *α*-deriv.), refluxed 0.5 hr. with 80% AcOH, yields 1,6-dibenzoyldulcitol (VII), m. 209° (the *α*-deriv. of F.), which yields a *2,3,4,5-tetra-Ac deriv.*, m. 225–6°. IV with 10% AcOH, refluxed 1 hr., gives 60% of *1,6-diacetyldulcitol*, m. 167–8°; $Pb(OAc)_4$ oxidation consumes 3 moles of oxidant in 18 or 67 hrs.; with $NaIO_4$ the theory of HCO_2H was formed. VII and $Pb(OAc)_4$ in 10 days gave values showing that 4.90 moles (calcd. 5) of oxidant had been consumed; $BzOCH_2$-CHO was isolated as the semicarbazone in 79% yield. The oxidation behavior of this series shows that the *β*-diacyl derivs. are 1,6-derivs. and that II is 2,3,4,5-, 2,4,-3,5- or 2,5,3,4-diacetonedulcitol; the derivs. possess meso structures, which fact accounts for their lack of optical activity. I with Ac_2O in C_5H_5N on standing overnight and pouring into H_2O gives a quant. yield of the *di-Ac deriv.*, designated *1,4-diacetyl-2,3,5,6-diacetone-D,L-galactitol* (reasons are given for preferring the name galactitol to dulcitol in designating non-meso structures of derivs. of III which carry in their names a numbering of the C atoms), m. 89°; *ditosyl deriv.* (VIII), m. 101°. Reaction with Ph_3CCl in C_5H_5N for 72 hrs. at room temp., followed by Ac_2O for 24 hrs., gives 95% of the *1-trityl-4-acetyl deriv.*, m. 107–8°. VIII with NaI in Me_2CO (1.5 hrs. at 100°) gives 96% of the *1-iodo-4-tosyl deriv.*, m. 120–1°. The di-Bz deriv. (IX) of I, refluxed 30 min. with 80% of AcOH, gives 9.1% of VII and 72.7% of *1,4-dibenzoyl-D,L-galactitol* (X), m. 170–1°, and then 202–3°; *2,6,5,6-tetra-Ac deriv.*, m. 113°. With $Pb(OAc)_4$ or $NaIO_4$ 2 moles of oxidizing agent are consumed but no acid is formed. These results indicate that I contains 1 free primary and 1 free secondary HO group and that it is a racemic form. Heating X at 210° for 15 min. and recrystg. from AcOH gives 90% of VII; this involves an acyl migration in which a racemic form is transformed into a meso form. I with BzCl in quinoline (6 hrs. at 100°) gives 60% of VI and 11% of IX, m. 83–4°; hydrolysis of VI with MeONa in $CHCl_3$ yields II; the formation of VI results from an acetone shift during the benzoylating reaction. In C_5H_5N I and BzCl give 4% of VI and 86% of IX. IX and BzCl in quinoline (6 hrs. at 100°) do not give VI nor is IX changed on heating at 100° for several hrs. or by passing HCl through the melt. Heating I in quinoline for 6 hrs. at 100°, followed by reaction with BzCl, gives 4.4% of VI and 72.5% of IX; however, if quinoline·HCl is present during the heating there results 42.4% of VI and 39% of IX. C. J. West

The production of pure lactic acid. Lee T. Smith and H. V. Claborn. *Ind. Eng. Chem., News Ed.* **17**, 641 (1939).—The sepn. and hydrolysis of lactic acid esters yield pure water white lactic acid which can meet specifications for all grades. One mole of dry Ca lactate, or 2 moles of Na lactate, dissolved in 10–20 moles MeOH and heated at refluxing temps. 4–8 hrs. After again filtering, the MeOH is distd. off at atm. pressure; the H_2O and most of the ester are distd. off *in vacuo*. The residue in the still pot is recovered for use in a subsequent batch. One part distillate is dild. with 2–3 parts distd. water and fractionated slowly at atm. pressure. The lactic acid remaining in the still pot is evapd. *in vacuo* to the desired concn. A yield of 85% is attainable. W. C. Ebaugh



The combination of cysteine with sugars. Maxwell D. Schubert. *J. Biol. Chem.* **130**, 601–3(1939); cf. *C. A.* **30**, 5940[8].—Cysteine combines with arabinose, xylose, glucose, mannose, galactose and lactose in a mole to mole ratio with the elimination of a mole of H_2O in neutral soln. and at room temp. The compds. are similar to the thiazolidines formed from cysteine and simple aldehydes. In a soln. contg. excess $NaHCO_3$ none of the compds. gives a pos. thiol test with Na nitroprusside. No compd. with fructose could be isolated. Arabinose compd. m. 153°, xylose 133°, glucose 167°, mannose 171°, galactose 138°, lactose 130°, all with decompn. A. P. Lothrop

A new synthesis of cystine. John L. Wood and Vincent du Vigneaud. *J. Biol. Chem.* **131**, 267–71(1939).—In the new synthetic method for the prepn. of cystine, $PhCH_2SH$ is condensed with HCHO in the presence of HCl. The benzylthiolmethyl chloride is then condensed with phthalimidomalonic ester and the product is hydrolyzed to produce benzyl-*dl*-cysteine. The benzyl group is removed by Na in liquid NH_3 and the *dl*-cystine is formed from the *dl*-cysteine by oxidation. The method lends itself to the introduction of isotopes into the cystine mol. A. P. Lothrop

Xanthates of metals of Group VI. Lamberto Malatesta. *Gazz. chim. ital.* **69**, 408–16(1939).—To a soln. of 0.2 mol. $(NH_4)_2MoO_4$ and 0.4 mol. $EtOCS_2K$ (I) in 200 cc. H_2O is added about 200 g. ice and a slow current of SO_2 is then passed through. When all the pptn. has occurred and the soln. clears, the gas flow is stopped and the liquid left alone for 4–6 hrs. at the low temp. It is then filtered with suction, washed with EtOH and dried over $CaCl_2$. After dissolving in the least amt. of C_6H_6 at 40–50° and filtering, 2 vols. of ligroin are added and the soln. is cooled without agitation. The green crystals of *Mo ethylxanthate* (II) give intense violet colorations in various solvents, m. 118.5° (slight decompn.), have a magnetic susceptibility χ_M -250×10^{-6} and the formula $Mo_2O_3(CS_2OEt)_4$. Three mols. C_5H_5N react with one of II in C_6H_6 giving an addn. compd. II in dil. soln. treated with KCN in a little H_2O and Me_2CO gives an exchange reaction and the compd. $Mo_2O_3(CN)_4.4H_2O$. II in Me_2CO treated with excess solid KCN gives a green powder which, when washed with abs. EtOH, then MeOH and recrystd. from H_2O, appears to have the formula $K_n[Mo(OH)_2(CN)_4]$ where *n* is 3 or 4. The *methylxanthate* was similarly prepd., decompg. 100 20° without melting, χ_M -202×10^{-6}. *Propylxanthate* (III) was more difficult to crystallize, m. 89–91° (slight decompn.). The *isopropylxanthate*, prepd. as the others, crystallizes more readily than III and is more stable, m. 114°, χ_M -280×10^{-6}. The *butylxanthate*, sepn. from the reaction mass with ligroin, m. 75°; the *isobutylxanthate* m. 106–7.5° (slight decompn.); the *isoamylxanthate* m. 105° (decompn.); the *cyclohexylxanthate* m. 121° (decompn.). Since all these xanthates proved to be diamagnetic, it is believed that the structure

proposed by Montequi (cf. *C. A.* **11**, 2864), is incorrect and the following is advanced, wherein Mo exists in both a sexi- and quadrivalent condition:

Such a structure also explains the intense colors of the solns. of the compds., the metallic appearance of their crystals and the great absorption of light in the visible region. It was impossible to prep. similar compds. of W whether in tri- or quinquevalent condition, which fact apparently indicates their instability or nonformation under normal conditions. A concd. aq. soln. of $MeOCS_2K$ and $UO_2(NO_3)_2$ gave the corresponding reddish orange xanthate in very low yields. The *ethyl-*, *isoamyl-*, *isopropyl-*, *propyl-*, *butyl-*, *isobutyl-* and *cyclohexylxanthates* of U were likewise prepd., ligroin being used to ppt. the crystals from the solvent, usually

ketones. The data obtained which lead to this conclusion are the rates of iodination of these ketones and the ionization consts. obtained from the ultraviolet absorption spectra of their acid solns. A. B. Garrett

The effect of nuclear and side-chain substitution on the oxonium ion-catalyzed iodination of acetophenone derivatives. Lois Zucker and Louis P. Hammett. *J. Am. Chem. Soc.* **61**, 2779–84(1939).—The rates of iodination of several ketones were measured in aq. $HClO_4$ by a colorimetric method. These rates are compared with those reported for some of the same ketones in aq. 75% AcOH 0.5 *M* with respect to HCl. No steric hindrance was found in the iodination of 2,4,6-trimethylacetophenone. A. B. Garrett

3-Chloromethyl-4-methoxybenzaldehyde. Benno Reichert and Karl auf dem Kampe. *Arch. Pharm.* **277**, 361–71(1939).—The present study is undertaken to det. the fitness of this aldehyde to serve in the synthesis of *drug products*. The following derivs. of this aldehyde have been prepd. and characterized: *1-(3'-chloromethyl-4'-methoxyphenyl)-2-nitroethylene*, $C_{10}H_{10}O_3NCl$, greenish yellow, m. 118°; *1-(3'-hydroxymethyl-4'-methoxyphenyl)-2-nitroethylene*, $C_{10}H_{11}O_4N$, yellow, m. 104–5° (*Ac deriv.*, greenish yellow, m. 131–2°); *1-(3'-chloromethyl-4'-methoxyphenyl)-2-nitro-1-propylene*, $C_{11}H_{12}O_3NCl$, yellowish green, m. 80°; *1-(3'-hydroxymethyl-4'-methoxyphenyl)-2-nitro-1-propylene*, $C_{11}H_{13}O_4N$, yellow, m. 90° (*oxime*, m. 119–20°, yields on reduction *β-(hydroxymethyl-4-methoxyphenyl)ethylamine*, $C_{10}H_{15}O_2N$, m. 147–8°); *3-hydroxymethyl-4-methoxycinnamic acid*, $C_{11}H_{12}O_4$, m. 190–1°, gives on catalytic hydrogenation *3-methyl-4-methoxyhydrocinnamic acid*, $C_{11}H_{14}O_3$, m. 98–9° (*Me ester*, m. 45°); *p-methoxyisophthalic aldehyde*, $C_9H_8O_3$, m. 123–4° (*dioxime*, yellow, m. 170–2°), yields on oxidation *p* methoxyisophthalic acid, m. 273° in agreement with the literature. 17 references W. O. E.

Exchange of the amine residue in the inner complex salts of Schiff bases. P. Pfeiffer and H. Glaser. *J. prakt. Chem.* **153**, 265–84(1939).—Salicylaldehydemethylimine Cu complex (I) is conveniently prepd. by warming 12 g. of *o*-HOC_6H_4CHO (II) in 100 cc. MeOH and 13 g. of 25% $MeNH_2$ at 60° with 10 g. $Cu(OAc)_2$ in 80 cc. H_2O; the green needles m. 158°; in 1 case brown leaflets were obtained; from C_5H_5N green prisms with 1 mole C_5H_5N sep. The anil analog (III) of I results from the Cu complex of II and PhNHOH, red-brown needles, m. 234–6°, or dark green crystals with C_5H_5N. The ethylenediimine analog (IV) of I does not react with *o*-$C_6H_4(NH_2)_2$, $MeNH_2$ or $PhNH_2$. The *o*-phenylenediimine analog (V) of I and excess of $C_2H_4(NH_2)_2$ in EtOH or C_5H_5N give IV but it does not react with $MeNH_2$ or $PhNH_2$. I and $C_2H_4(NH_2)_2$ give IV; *o*-$C_6H_4(NH_2)_2$ gives V but $PhNH_2$ does not give III in EtOH or C_5H_5N. III and $C_2H_4(NH_2)_2$ give IV; *o*-$C_6H_4(NH_2)_2$ gives V; $MeNH_2$ gives I. The Cu complex of 2,1-$HOC_{10}H_6CHO$ and $C_2H_4(NH_2)_2$ give the *Cu complex of β-hydroxy-α-naphthaldehyde ethylenediimine* (VI), olive-brown with metallic luster, does not m. 250°; *propylenediimine analog*, yellow needles from Me_2CO or red-brown leaflets from $CHCl_3$; *o-phenylenediimine analog* (VII), red-brown needles, does not m. 250°; *the imine analog* (VIII), olive-green leaflets, m. 246–8°; *methylimine analog* (IX), brown or green, m. 233–4°; heating transforms the green form into the brown; *ethylimine analog* (X), olive-green; *benzylimine analog*, light yellow-olive needles; *anil analog* (XI), red-brown, m. 237–8°. VI and *o*-$C_6H_4(NH_2)_2$ do not give VII; it also does not react with $MeNH_2$ or $PhNH_2$. VII gives a nearly quant. yield of VI with $C_2H_4(NH_2)_2$ but it does not react with $MeNH_2$ or $PhNH_2$. IX and $C_2H_4(NH_2)_2$ give a quant. yield of VI; *o*-$C_6H_4(NH_2)_2$ gives VII and $PhNH_2$ gives XI. XI and $C_2H_4(NH_2)_2$ give VI; *o*-$C_6H_4(NH_2)_2$ gives VII; $MeNH_2$ yields IX. C. J. West

Molecular compounds in the binary system. Benzoic acid and nitrobenzoic, hydroxybenzoic and aminobenzoic acids. E. Vitale. *Atti X° congr. intern. chim.* **3**, 380–90 (1939).—Binary systems of BzOH (I), with nitrobenzoic (II), hydroxybenzoic (III), and aminobenzoic acids (IV) were examd. by means of thermal analysis. I (1 mol.) and the *o*-, *m*- and *p*-isomers of II (1 mol.) gave mol. compds., m. 121°, 139° and 186°, resp. The *o*- and *m*-isomers of III and the *m*- and *p*-forms of IV formed no mol. compds. with I. The *o*-isomer of IV (2 mols.) and I (1 mol.) gave a mol. compd., m. 118° (decompn.). A table of the dissocn. consts. of the various acids is given from which it is shown that Kendall's hypothesis (*C. A.* **8**, 2697) that the formation of a mol. compd. is dctd. by the diverse value of the dissocn. consts. of the reacting substances is confirmed except in the non-formation of a compd. between I and the *o*-form of III, which has a higher dissocn. const. than I. Thus substitution of the NO_2 group by the groups OH and NH_2 makes the formation of mol. compds. dubious. C. R. Addinall

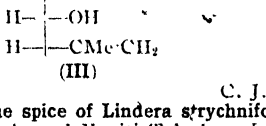
Relation between chemical constitution and local anesthetic activity. III. Substituted cinnamic acid esters of dialkylamino alcohols. W. A. Lott and W. G. Christiansen. *J. Am. Pharm. Assoc.* **28**, 499–502(1939); cf. *C. A.* **32**, 8391⁶.—Eighteen new compds. were prepd., all as *hydrochlorides* (10 β-diethylaminoethyl α- and β-alkylcinnamates: *α-Me*, m. 133.0–4.5°; *α-Et*, m. 145°; *α-Pr*, m. 125–6°; *α-iso-Pr*, m. 152–3°; *α-Bu*, m. 101.5–6.5°; *α-Am*, m. 83–5°; *α-ethyl-o-chloro*, m. 121.5–8.0°; *α-ethyl-p-dimethylamino*, m. 170–1°; *β-Me*, m. 141–2°; *β-Pr* (no m. p. given); 3 γ-diethylaminopropyl α-alkylcinnamates: *α-Et*, m. 143.8–4.4°; *α-ethyl-p-amino*, m. 191–2°; *α-ethyl-o-amino*, m. 160.0–0.5°; 5 *N*-(β-diethylaminoethyl)-α-alkylcinnamamides: *α-Me*, m. 111.0–2.5°; *α-Et*, m. 163–4°; *α-Pr*, m. 134.2–4.9°; *α-Bu*, m. 124.5°; *α-Am*, m. 95–5°). Methods used for their prepn. and purification are indicated, and their m. ps. are given. All had pronounced local anesthetic activity. Lengthening the substituent alkyl group attached to the α-C of the cinnamic radical brings about a progressive increase in anesthetic potency, which is attributable to the increase in the organotropic portion of the mol. Substitution in the β- instead of the α-position did not influence the anesthetic activity very greatly, nor did substitution in the ring by Cl, NMe_2 or NH_2. IV. **Local anesthetics containing an ephedrine-like nucleus.** *Ibid.* 502–6.—The following 6 *new compds.* were synthesized: 1-phenyl-2-dimethylamino-1,3-propanediol 3-benzoate-HCl, m. 181–1.5°; 1-phenyl-2-diethylamino-1,3-propanediol 3-benzoate-HCl, m. 149–50°; 1-phenyl-2-diethylamino-1,3-propanediol 3-α-ethylcinnamate-HCl, m. 203–4°; 1-phenyl-2-diethylamino-1,3-propanediol 3-carbanilate-HCl, m. 177–8°; 1-phenyl-2-diethylamino-1,3-propanediol 3-*p*-ethoxybenzoate-HCl, m. 198–9.5°; 3-phenyl-3-methoxy-2-diethylaminopropyl carbanilate-HCl, m. 215–16°. All 6 proved to be potent local anesthetics in preliminary pharmacol. tests, but no vasopressor activity was observable in actual blood-pressure measurements. A. Papineau-Couture

Aldehydo acids and aldo-enol lactones. I. The possibility of condensation of aconic acid with aldehydes and ketones. M. M. Shemyakin and I. A. Red'kin. *J. Gen. Chem.* (J. S. S. R.) **9**, 442–6(1939).—It is planned to synthesize relatively simple compds. contg. the essential group of the cardiac glucosides and study them pharmacologically. Aconic acid (I) is used so that H_2O-sol. salts can be obtained. When I is heated for 1 hr. at 100–5° with excess 3% *m*-$NO_2C_6H_4CHO$ or furfural in the presence of 5 drops of $EtNH_2$ catalyst, it gives 14.5% *benzalaconic acid*, m. 201–2°, 18.5% *m-nitrobenzalaconic acid*, darkens to 290° but does not melt, or 41% furfuralaconic acid, darkens to 290° without melting, resp. All these compds. are insol. in H_2O but dissolve without change in cold alkali, and all form Ag mirrors. I does not condense with ketones. II. **The synthesis of α-hydroxy-β-phenyl-γ-aldo-enol lactone (3-hydroxy-4-phenylfuran-2-one).** M. M. Shemyakin. *Ibid.* 484–90.—When $PhCH_2CHO$ (I) is heated with $HOCH(OEt)CO_2Et$ (II) and Ac_2O at 140–5° for 20 hrs., it gives 29.5% *Et β-formyl-β-phenylacrylate* (III), b₂ 110–14° (*semicarbazone*, m. 167°), and 13% *acetyl α-hydroxy-β-phenyl-γ-aldo-enol lactone* (IV), m. 140–1°. The first step in this reaction is the elimination of EtOH between I and II with formation of the intermediate $HOCH(CO_2Et)CH(CHO)Ph$, which then decomps. in 2 directions to give III and IV. Hydrolysis of III with 5% HCl gives *β-formyl-β-phenyl-*

acrylic acid (V), m. 161–2°. When IV is hydrolyzed with 10% HCl, the lactone ring is opened and V is also formed. The reaction between I and II can be used to synthesize aldo-enol lactones with substituents on the β-C atom, but it is not general, since when PhCH:CHOCOMe replaces I in the reaction, action is slight and no identifiable products can be isolated. III. **Some specific peculiarities of γ-aldo-enol lactones and unsaturated aldehydo acids.** *Ibid.* 491–5. Compds. of this type do not add Br to the double bond of the lactone ring or to one adjacent to it. Their reactivity in many reactions is very great, however. Thus, acetyl-α-hydroxy-β-phenyl-γ-aldo-enol lactone and β-formyl-β-phenylacrylic acid or its Et ester, when heated for 2–3 min. at 80–90° with 2–4% NaOH give a dibasic acid, $C_{18}H_{16}O_4$, m. 195–6° on slow heating and 206–8° on rapid heating (Me ester, m. 198–9°). It is probably a new truxinic acid. H. M. Leicester

Synthesis of homoisovanillic acid. H. W. Bersch. *Arch. Pharm.* **277**, 271–86(1939).—Isovanillin itself was not used as starting material, since its cyanohydrin is quite unstable, readily suffering cleavage into isovanillin and HCN, but rather carbethoxyisovanillin, RCH:O (R = MeO(EtO$_2$CO)C$_6$H$_3$) (I), m. 58–9°, which is conveniently and quantitatively prepd. from isovanillin and ClCO$_2$Et. The bisulfite compd. of I is convertible to the cyanohydrin (II), m. 98°, which can be transformed into the Me ester (III), a viscous oil which could be crystd., by gaseous HCl in its MeOH-Et$_2$O soln. By way of an imido ester-HCl. The yield of III is only moderate (about 50%). During the passage of HCl gas a part of II is split into HCN and I, which may however be recovered without difficulty and again applied to the prepn. of cyanohydrin and ester. Further transformation of III into the chlorinated ester RCHClCO$_2$Me, reduction to RCH$_2$CO$_2$Me and sapon. to homoisovanillic acid (IV), m. 127–9°, proceeds smoothly. The yields of IV referred to the isovanillin used amt. to 30–40%. In the course of this study the following compds. were prepd. and characterized: *Benzoylvanillin benzoylcyanohydrin*, $C_{24}H_{19}O_5N$, yellowish crystals, m. 146.5–7.5°, by the interaction of vanillin and BzCl in Et$_2$O with aq. KCN; reduction in tetralin with Pd sponge gave *4-benzoyloxy-3-methoxybenzyl cyanide*, $C_{16}H_{13}O_2N$, brownish crystals from ligroin, m. 110°. Similarly, *benzoylisovanillin benzoylcyanohydrin*, viscous oil, from the bisulfite extn. about 60% of the applied isovanillin, m. 74–5°, could be isolated. *3-Hydroxy-4-methoxynitrostyrene*, $C_9H_9O_4N$, m. 155–6°, by interaction of isovanillin, MeNO$_2$ and NaOH soln., followed by addn. of dil. H_2SO_4, gives on reduction with Pd sponge (C_5H_5N as catalyzer) *3-hydroxy-4-methoxyphenylacetaldoxime*, $C_9H_{11}O_3N$, m. 146–7°. Acetisovanillin, $C_{10}H_{10}O_4$, m. 86° (Pschorr (*Ber* **35**, 4387(1902)) gave 61°); *isovanillin triacetate*, $C_{14}H_{16}O_7$, m. 117–18°, both by acetylation with Ac$_2$O. 3-Hydroxy-4-methoxybenzyl alc. (isovanillyl alc.), m. 132°, by hydrogenation of isovanillin, yields with Na and abs. MeOH *3-benzyloxy-4-methoxybenzyl alc.* (benzylisovanillyl alc.), $C_{15}H_{16}O_3$, m. 70–1°, which with CSCl$_2$ gives the corresponding *chloride*, $C_{15}H_{15}O_2Cl$, m. 70–5°. *3-Nitro-4-methoxybenzyl cyanide*, $C_9H_8O_3N_2$, yellow, m. 86–7°, from the corresponding chloride with NaCN, gives on sapon. *3-nitro-4-methoxyphenylacetic acid*, $C_9H_9O_5N$, bright yellow crystals, m. 133–4° (*Et ester* (V), m. 58–9°; *Me ester* (VI), m. 102°), which on reduction yields *3-amino-4-methoxybenzyl cyanide*, yellow, m. 40°, discolors in the light (*HCl salt*, m. 202°). Reduction of V and VI yields yellow oils, b$_1$ 151–2° and 147–8°, resp.; the corresponding *HCl salts* m. 166–7° and 190–1°, resp. W. O. E.

Catechols isolated from tea leaves. W. B. Deijs. *Rec. trav. chim.* **58**, 805–30(1939).—*l*-Epicatechol, catechol gallate and 5′-hydroxycatechol were isolated in a cryst. state from various samples of tea leaves from Java. From 2 to 2.5% of amorphous tannins (I) (on the basis of dry leaves) was also isolated. These show $[\alpha]_D$ varying from −94.3° to −112.3°; 3 Ac derivs., m. 110–23°, 108–23°, 112–24°, and with $[\alpha]_D^{15}$ −93.4°, −92.4° and −70.5°, were prepd. The I could be sepd. into an Et$_2$O-sol. and Et$_2$O-insol. fraction, with $[\alpha]_D$ −123.3° and −101.2°, −123.8° and −108.2°; −100.9° and −82.2°. I with tannase gives 25.6–28.5% gallic acid; with 5% H_2SO_4 the acid split off is not more than 15.2% (after boiling 66 hrs.). Sugar could not be detected in any of the I prepns. In the detn. of tannin by the HCHO-HCl method, no advantage is gained by boiling the ppt. The conversion factor of 0.97 is adopted for the detn. of tannin. The I which dissolves completely or at least to a large extent in H_2O is pptd. with gelatin; the ppt. seps. readily when a satd. soln. of NaCl contg. H_2SO_4 is added, but the filtrate always shows the tannin reaction quite clearly. The portion not pptd. amounts to 8–20% of the total I. Purification of I through the Pb salt still gives an amorphous product, but the rotation and that of the Ac deriv. are higher and the m.-p. range of the Ac deriv. is less extensive. The compn. of I is discussed. C. J. West



Syntheses of glucosides. XI. Cichoriin. Frank S. H. Head and Alexander Robertson. *J. Chem. Soc.* **1939**, 1266–7; cf. *C. A.* **28**, 1338⁸.—BzCl added to 3.5 g. of esculetin in 2% aq. NaOH at 0° gives 2.7 g. of the *6-O-Bz deriv.* (I), m. 198°, and 1.5 g. of the di-Bz deriv., m. 186°. I with MeI and K_2CO_3 in Me$_2$CO gives 6-benzoyloxy-7-methoxycoumarin, m. 217–18° (Seka and Kallir, *C. A.* **25**, 3980, give 211°); NH_3 in MeOH gives 7-*O*-methylesculetin. I and *O*-tetraacetyl-α-glucosidyl bromide with Ag_2O give *7-O-tetraacetyl-β-glucosidoxy-6-benzoyloxycoumarin*, m. 218°; NH_3 in MeOH gives 6-hydroxy-7-β-glucosidoxycoumarin, m. 213–14°, $[\alpha]_D^{20}$ −104° (3 g. in 100 cc. 50% aq. dioxane); this is identical with natural cichoriin (Merz, *C. A.* **27**, 2685); penta-Ac deriv., m. 218°. C. J. West

Aluminum chloride, a new reagent for the condensation of β-ketonic esters with phenols. IV. The condensation of 4-acylresorcinols with ethyl acetoacetate. C. V. Dehwala and N. M. Shah. *J. Chem. Soc.* **1939**, 1250–3; cf. *C. A.* **33**, 5485.—Respropiophenone (4.2 g.) and 3.25 g. of AcCH$_2$CO$_2$Et in PhNO$_2$ with AlCl$_3$, heated 1 hr. at 120–30°, give 2 g. of *5-hydroxy-6-propionyl-4-methylcoumarin* (I), m. 164–5°; alkali gives a deep-yellow color; *Ac deriv.*, m. 167–8°; *oxime*, m. 257–8°. 5-Hydroxy-4-methylcoumarin and EtCOCl, heated for 10 hrs. (finally at 120°), give the *5-propionoxy deriv.*, m. 100–1°; heating with AlCl$_3$ at 120–30° for 2 hrs. gives I. I with Ac$_2$O and AcONa at 160–70° for 10–11 hrs. gives *2′,3′,4-trimethylchromano-7′,8′,6,5,α-pyrone*, m. 241–2°. Reduction of I with Zn-Hg in EtOH gives *5-hydroxy-4-methyl-5-propylcoumarin*, m. 152°, which gives a deep-yellow color with alkali. Resbutyrophenone (3 g.) and AcCH$_2$CO$_2$Et give 1.5 g. of *5-hydroxy-6-butyryl-4-methylcoumarin* (II), m. 141–2°; FeCl$_3$ gives a deep-red color and alkali a deep-yellow color; *Ac deriv.*, m. 167°; *Me ether*, m. 83–4°; *oxime*, m. 210°. *5-Butyroxy-4-methylcoumarin*, m. 100–1°; with AlCl$_3$ it gives II. Ac$_2$O-AcONa transforms II into *4′,2′-dimethyl-3′-ethylchromono-7′,8′,6,5,α-pyrone*, m. 201–2°. Reduction of II gives *5-hydroxy-4-methyl-6-butylcoumarin*, m. 145–6°; alkali gives a deep-yellow color. 2,4-(HO)$_2$C$_6$H$_3$COCH$_2$Ph (2.3 g.) and AcCHCO$_2$Et give 1.25 g. of *5-hydroxy-6-phenylacetyl-4-methylcoumarin*, m. 172–3°; it gives a strong FeCl$_3$ reaction and turns deep yellow in alkali; *Ac deriv.*, m. 142°; *Me ether*, m. 78–9°; *oxime*, m. 257°. Ac$_2$O-AcONa gives *3′-phenyl-4,2′-dimethylchromono-7′,8′,6,5,α-pyrone*, m. 237–8°. *4-p-Tolylresorcinol* and AcCH$_2$CO$_2$Et give *5-hydroxy-6-(p-toluoyl)-4-methylcoumarin*, m. 204–5°, which gives a reddish brown color with FeCl$_3$ and a yellow color with alkali; *Ac deriv.*, m. 192–3°; *4′-p-tolyl-4-methylcoumarino-7′,8′,6,5,α-pyrone*, m. 238–9°; BzCl does not give the expected Bz deriv. The above 4-acylresorcinols do not condense with AcCH$_2$CO$_2$Et in the presence of H_2SO_4; their reactivity appears to be brought out only in the presence of AlCl$_3$ which has a sp. action in effecting condensation in the otherwise very inaccessible 2-position of the resorcinol mol. C. J. West

Products obtained by saturation of 3-carene with hydrochloric acid gas. V. N. Krestinskiĭ and S. Malevskaya. *J. Applied Chem.* (U. S. S. R.) **12**, 878–85(in French, 885)(1939).—The satn. of 3-carene with an excess of HCl gas yielded mainly monohydrochlorides (83%) and in smaller amts. dihydrochlorides. The monohydrochlorides

represented mixts. of products corresponding to dipentene and sylvestrene; they had a monocyclic structure with an ethylene bond in the ring and Cl at the tertiary position in the isopropyl group. Possibly, the small amt. of monohydrochloride preserved the carene structure. Thus, HCl was added with opening of the 3-membered ring and the ethylene linkage was preserved. The opening of the ring proceeded in 2 directions leading to the formation of dipentene and sylvestrene derivs. Both these hydrocarbons can be isolated from the corresponding hydrochlorides by splitting off HCl (with aniline, for instance). The dihydrochlorides also represented mixts. of dihydrochlorides of dipentene and sylvestrene. The ethylene linkage (in respect to HCl) in carene was more stable than the trimethylene ring. A. A. Podgorny

Menthone series. XVI. *d*-Neoisopulegol. Andrew G. Short and J Hinton Read. *J. Chem. Soc.* **1939**, 1306–9; cf. *C. A.* **33**, 6816⁸.—*d*-Pulegone (200 g.), with α_D^{19} 19.97°, n_D^{19} 1.4859, reduced with (iso-PrO)$_3$Al (the prepn. of which is given), during which a slow const.-vol. distn. is conducted through a 30-cm. Vigreux column, dry iso-PrOH added to replace the distillate, the temp. being kept at 120° for several hrs. and then gradually raised to 170°, gives after 20 hrs. 34 g. of a fraction b_{17} 55–82° and 255 g. of a fraction b_{17} 82–107°, $\alpha_D^{19.5}$ 58.03°, $n_D^{19.5}$ 1.4836. Esterification of the larger fraction with 3,5-$(O_2N)_2C_6H_3$-COCl in C_5H_5N at 0° for 16 hrs., followed by the addn. of 100 cc. of concd. HCl in 100 cc. H_2O, extn. with Et_2O, washing with 2 *N* NaOH and distn. with steam, gives 153 g. of unesterified material (I); after removal of some 3,5-$(O_2N)_2C_6H_3CO_2H$ by shaking the Et_2O soln. with 2 *N* NaOH, the residue is crystd. from MeOH and then from MeOH-$CHCl_3$, giving 11.5 g. (6%) of the *3,5-dinitrobenzoate*, m. 138–9°, α_D^{19} 45° ($CHCl_3$, *c* 1), of *d*-neoisopulegol (II), b_{17} 95°, d_4^{25} 0.9107, n_D^{25} 1.4686, α_D^{18} 25.30°, $[\alpha]_D^{18}$ 39.3° (EtOH, *c* 1), $[R_L]_D$ 47.13 (calcd. 47.24). On catalytic reduction II gives *d*-neomenthol exclusively and thus possesses the mol. configuration III. I was sepd. into 2 fractions by distn.; the 1st is essentially *d*-$\Delta^{3,8(9)}$-*p*-menthadiene; the 2nd b_{17} 100–5°, α_D^{19} 42.7°; it yields a semicarbazone, m. 172°, $[\alpha]_D^{23}$ 68.2° ($CHCl_3$, *c* 1), but it is not α-pulegone, for its *2,4-dinitrophenylhydrazone*, bright red, m. 149–50°, $[\alpha]_D^{19}$ 116° ($CHCl_3$, *c* 0.5). Reduction of this ketonic fraction gives *l*-menthone. Thus the reduction in question appears to consist of a mixt. of pulegols and isopulegols. The isopulegol series contains 4 members: *l*-isopulegol, *d*-neoisopulegol, *d*-isoisopulegol and *d*-neoisoisopulegol.

(III)

C. J. West

Constituents of the spice of Lindera strychnifolia VIII. III. Heisaburo Kondo and Keniti Takeda. *J. Pharm. Soc. Japan* **59**, 504–19(in German, 169–9)(1939); cf. *C. A.* **24**, 5750.— The ether ext. of 210 kg. *Lindera strychnifolia* Vill gave 230 g. crude linderane (I) (0.11%), 290 g. crude linderene (II) (0.14%), 200 g. linderol fraction (III) b_5 70–100° (0.1%), 957 g. ester fraction b_5 100–45° (0.46%), and others (775 g.) b_5 145–70° (0.37%). I, $C_{15}H_{16}O_4$ ($C_{16}H_{18}O_4$ or $C_{12}H_{14}O_3$), m. 187°. Oxidation of I in acetone with $KMnO_4$ gave a syrupy material, differing from the original compd. Catalytic oxidation of I gave a neutral compd., which was not identified. I and O_3 gave AcH, HCHO, and a compd., which gave on oxidation succinic acid. II, $C_{15}H_{18}O_2$ or $C_{16}H_{20}O_2$, m. 145°. Dihydrolinderene and O_3 gave HCHO and an acid which gave 2 Me esters, b_3 130–50° and $b_{0.01}$ 170–90°. Attempts to prep. acid amides failed. Oxidation of II with Cr_2O_3 in the cold gave an acid, $C_{14}H_{18}O_5$, decompg. 192–5°, inactive toward maleic anhydride, semicarbazide and $HONH_2$, a neutral compd., $C_{15}H_{18}O_4$, m. 140°, sol. in KOH, and a neutral compd., $C_{15}H_{16}O_2$, m. 140–60°, which forms a semicarbazone. Dehydrogenation of II with Pd-asbestos gave *linderazulene*, $C_{15}H_{18(16)}$ (?), m. 103–6°. Catalytic reduction of II (35 g.) gave the following *compds.*: (IV) b. 120–40° (12 g.), (V) b_5 150–70° (12 g.), and (VI) $b_{0.05}$ 130–5°, $[\alpha]_D^{23}$ −53.07° (in acetone). V gave 2 compds., one b_5 150° and the other, $C_{15}H_{26(24)}O_2$ (VI), m. 118–19°, $[\alpha]_D^{23.5}$ −34.78° (in abs. alc.). VI forms an Ac deriv. m. 77–9°; Bz deriv., m. 169–70°. Reduction of II in acetone failed to give VI. III, identical with *l*-borneol, $C_{10}H_{18}O$, m. 204°, $[\alpha]_D^{18}$ −36.42°; phenylurethan, m. 139.5°; *p*-nitrobenzoate, m. 136.5°. Oxidation of III with HNO_3 gave a ketone, m. 177.5°, $[\alpha]_D^{17}$ −44.84° (in alc.); oxime, $C_{10}H_{17}ON$, m. 119°. F. I. Nakamura

Camphorone and pulegenone. Products of hydrogenation and their structure. I. Raymond Calas. *Bull. soc. chim.* **6**, 1374–82(1939).—Thermal decompn. of Th *d*-camphorate (I) gives a mixt. of *dl*-2-methylcyclopentanone (II), *dl*-camphorone (III) and slightly active pulegenone (IV). I (200 g.) was heated *in vacuo* in a Pyrex tube by an elec. furnace at 250–400°. The distillate was extd. with Et_2O, yielding 63% of a crude product, $[\alpha]_{5461}^{20}$ 0.13°, fractionated *in vacuo* to give 5% of II, b_{15} 38.40° (semicarbazone, m. 184°); 17% of IV, b_{15} 76° (semicarbazone, m. 184°); and 65% of III, b_{15} 85°, d_4^{20} 0.9325, d_4^{25} 0.9308, n_{5893}^{20} 1.48084, n_{4358}^{20} 1.49884, M. R. 42.18 (calcd. 41.31), η_{22} 1.831, surface tension 34, parachor 863 (calcd. 857) (semicarbazone, m. 197°; semicarbazide addn. compd., m. 134°). Regeneration from the semicarbazone gave IV, b_{764} 190–1°, b_{15} 76°, d_4^{20} 0.9146, d_4^{25} 0.9130, n_{5893}^{20} 1.45916, n_{4358}^{20} 1.47125, M. R. 41.33 (calcd. 41.31), η_{22} 1.515, surface tension 34, parachor 863 (calcd. 857), $[\alpha]_{5893}$ 0.56°, $[\alpha]_{5780}$ 0.60°, $[\alpha]_{5461}$ 0.73°, $[\alpha]_{4358}$ 1.53°. Thus the phys. consts. of IV are less than those of III. Comparison of the exaltations noted with III and IV with those reported for isopropylidenecyclopentane, M. R. 36.74 (calcd. 36.47), exaltation 0.27, and isopropylcyclopentene, M. R. 36.29 (calcd. 36.17), exaltation −0.18, permits the explanation to a certain measure of the differences observed since the conjugation due to the CO group will accentuate the effect already present in the hydrocarbons. The Raman spectra of III and IV show considerable differences. **II. Hydrogenation with sodium in the presence of aqueous ether or of absolute alcohol.** *Ibid.* 1382–91.— III (35 g.) in a mixt. of 800 cc. Et_2O and 1500 cc. satd. $NaHCO_3$ was treated portionwise with 37 g. Na and the washed and dried Et_2O layer was evapd. and distd., yielding 4 g. III; 13 g. of a *pinacol*, $C_{15}H_{31}O_2$, m. 182–3°; and 15 g. of a crude *product* (V), b_{14} 81–2°, which did not give a cryst. *p*-nitrobenzoate but yielded 2 *acid phthalates* (VI, VII), m. 114° and 84°, resp. Sapon. of VI and VII with 15% KOH gave the corresponding *dihydrocamphorols* $C_9H_{18}O$, VIII: b_{15} 82.3, d_4^{23} 0.8926, n_{5893}^{23} 1.4496, n_{4358}^{23} 1.45970, M. R. 42.79 (calcd. 42.39), η_{23} 0.1317, surface tension 30.4, parachor 374 (calcd. 379), (*p-nitrobenzoate*, m. 91°), oxidized by CrO_3 in AcOH to a *dihydrocamphorone*, $C_9H_{16}O$, m. 198°, and IX, b_{15} 82.3 d_4^{23} 0.8968, n_{5893}^{23} 1.45196, n_{4358}^{23} 1.46168, M. R. 42.75 (calcd. 42.39), η_{23} 0.1653, surface tension 30.6, parachor 375 (calcd. 379) (*p-nitrobenzoate*, m. 58°), oxidized by CrO_3 to the above dihydrocamphorone. Sapon. rate measurements gave *K* values of 0.00531 and 0.0153 for VI and VII, resp., and consequently cis and trans structures are assigned to these isomers. Viscosity and reduction studies confirm this conclusion which is contrary to Auwer's rule. Since the alcs. correspond to the *cis*-dihydrocamphorone, the alc. VIII is the *cis,cis*-dihydrocamphorol and IX is the *cis, trans* isomer. Similar reduction of IV with Na in aq. Et_2O gave identical results. Reduction of III or IV by Na in abs. alc. gave similar results but the yield of VIII was smaller and very little pinacol was formed. **III. Hydrogenation in the presence of metal catalysts.** *Ibid.* 1391–1401.—In the presence of metal catalysts the ethylenic bond of III and IV is satd. primarily. With Raney Ni the reduction ceases at the ketone stage with formation of a mixt. of stereoisomeric dihydrocamphorones. Precise studies of hydrogenation under different conditions of dilu., solvent, catalyst and pH, were undertaken. Reduction of 200 g. III in 50 g. batches in 250 cc. alc. in the presence of 20 g. Ni per batch gave an over-all yield of 185 g. of crude *product*, b. 179–81°; semicarbazone, m.

204°. Fractionation from abs. alc. yielded 80% of a *semicarbazone* (X), $C_{10}H_{19}N_3O$, m. 209°, and 20% of an isomeric *semicarbazone* (XI), m. 198°. X and XI are evidently the semicarbazones of 2 stereoisomeric *dihydrocamphorones*, $C_9H_{16}O$. Similar results were obtained by the reduction of IV. C. R. Addinall

A new isomer with the structure of campholic acid, *l*-campholic acid. F. Salmon-Legagneur. *Bull. soc. sci. Bretagne* **15**, 110–16(1938).—Methods of prepn. and properties of the acid and its derivs. are given in detail (cf. *C. A.* **32**, 4969⁶). The alk. earth, ferrous and Ni salts of β-campholic acid are water-sol., the Zn, Cd, Co, ferric, Mn, Cu, Ag, mercuric mercurous, Sn, Pb, Sb, Cr and Al salts are not. The Cu and Co salts are readily sol. in ether, giving an addn. compd. with increased blue-green and intense rose colors, resp. 5 references. W. C. T.

Syntheses and crystallographic study of the esters of the nitriles of the camphoric [acid] series and of β-cyanocampholide. L. Berthois and J. Vène. *Bull. soc. sci. Bretagne* **15**, 117–23(1938).—The syntheses (*C. A.* **32**, 4564⁴; **33**, 5831⁸, 9080²) are very briefly described. The crystals of the α-Me (I) and α-Et (II) esters of β-cyanocampholic acid and β-cyanocampholide (III) were studied. The parameters *a*:*b* :*c* were: I (orthorhombic holohedrons) 0.927:1:0.709; II (2 slightly different forms of orthorhombic hemihedrons) 0.752:1:0.685; III (orthorhombic antihemihedrons) 0.508:1:0.596. Mech. and optical properties are given W. C. Tobie

Polyterpenoid compounds. I. Betulic acid from Cornus florida L. Alexander Robertson, Gabra Soliman and Edmund C. Owen. *J. Chem. Soc.* **1939**, 1267–73.—The bark of *Cornus florida* L. (1 kg.), extd. 3 times with 1 l. H_2O at room temp. for 24 hrs. and washed with 1.5 l. EtOH, then extd. 4 times with 2 l. boiling 95% EtOH for 5–7 hrs., the EtOH evapd. to crystn., the solid extd. with H_2O, dried, extd. with petr. ether and then with Et_2O, gives 300 g. crude acid and 200 g. of a dark oil sol. in petr. ether. Recrystn. from EtOH gives betulic acid (I), m. 316–18°, $[\alpha]^{22}_{5461}$ 7.89° (3.076 g. in 100 cc. C_5H_5N), identical with that from the oxidation of betulin (Ruzicka, *C. A.* **33**, 1703⁵); *Na salt*. Color reactions are given for I. I and Ac_2O in C_5H_5N at room temp. for 2–3 days give the *anhydride* (II) of the *O*-Ac deriv. of I and AcOH, m. 194–6°, which does not react with CH_2N_2; this also results on refluxing I with Ac_2O-AcONa for 1 hr.; with boiling 70% EtOH II gives betulin acetate, m. 289–91°, $[\alpha]^{22}_{5461}$ 7.70° (5.07 g. in 100 cc. $CHCl_3$), which regenerates II on boiling with Ac_2O-AcONa. I and *p*-$O_2NC_6H_4COCl$ in C_5H_5N appear to give the mixed anhydride but it could not be purified; heating in C_5H_5N for 15 min. on the water bath gives the *p-nitrobenzoate*, m. above 330°. I and Me_2SO_4 or CH_2N_2 in Et_2O give the Me ester (III), m. 223–4°, $[\alpha]^{22}_{5461}$ 8.01° (4.11 g. in 100 cc. $CHCl_3$); Ac_2O and C_5H_5N give the acetate, m. 201–2°, $[\alpha]^{22}_{5461}$ 18.06° (6.756 g. in 100 cc. $CHCl_3$), also prepd. from the *O*-Ac deriv. of I and CH_2N_2; deacetylation gives III. III yields a *β-nitrobenzoate*, m. 232–3°, and a *p-toluenesulfonate*, m. 172–4° (decompn.). I gives an *Et ester*, m. 201–2°, $[\alpha]^{22}_{5461}$ 11.44° (4.588 g. in 100 cc. $CHCl_3$); *acetate*, m. 185–6°, $[\alpha]^{22}_{5461}$ 14.33° (2.198 g. in 100 cc. $CHCl_3$). *O*-Acetylbetulic acid in EtOH or AcOH is reduced in 0.5 hr. to the dihydro deriv. (IV), m. 307–10°; Me ester, m. 236–7°, $[\alpha]^{22}_{5461}$ −3.31° (5.37 g. in 100 cc. $CHCl_3$); IV with EtOH-KOH gives the dihydro deriv. of I, m. 316–20°, whose *Me ester* m. 238–40°. *Et ester*, m. 208°; *O-Ac deriv.*, m. 205°. Me *O*-acetylbetulate with BzO_2H gives an *oxide*, $C_{33}H_{50}O_6$, m. 202°; 1 mole of O is required for oxidation; the O no. for the acid is also 1. The gradual soln. of I in AcOH satd. with HBr gives a violet and then a blue color; ppta. with H_2O and crystn. from $CHCl_3$ and then C_5H_5N gives the *acetate*, m. above 350°, of *lactone A*, $C_{32}H_{48}O_3$, m. above 320°, $[\alpha]^{22}_{5461}$ 75.18° (1.37 g. in 100 cc. $CHCl_3$); the acetate is unchanged on heating with Ac_2O-C_5H_5N for 1 hr.; it is also formed by heating the *O*-Ac deriv. of I with 98–100% HCO_2H for 5 hrs. Boiling I with HCO_2H for 5 hrs. gives the *formate*, m. above 350°, of *lactone B*, m. above 330°, $[\alpha]^{22}_{5461}$ 59.05° (2.1 g. in 100 cc. $CHCl_3$). Addn. of 5% Br in AcOH to *O*-acetylbetulic acid in Et_2O gives in 3 hrs. the *lactone* of *O-acetylbromobetulic acid*, $C_{32}H_{49}O_4Br$, m. 290° (decompn.); the reaction in AcOH contg. a little H_2O gives the *di-Br deriv.*, m. 290–5° (decompn.). III gives a poly-Br lactone which has not been obtained pure. C. J. West

Terphenyl series. II. Hydroxy- and methyl-*p*-terphenyls. H. France, I. M. Heilbron and D. H. Hey *J. Chem. Soc.* **1939**, 1283–7; cf. *C. A.* **33**, 5556.—4-Ac(NO)NC_6H_4Ph (I) in PhOMe at 18° for 48 hrs. gives a mixt. of II and III. 2-HOC_6H_4Ph and MeI with KOH in EtOH give *2-methoxy-p-terphenyl* (II), m. 118–19°. 4-$MeOC_6H_4C_6H_4NHAc$ and N oxides in AcOH at 8° give *4′-nitrosoacetamino-4-methoxybiphenyl*, yellow, detonates at 103°; C_6H_6 gives *4-methoxy-p-terphenyl* (III), m. 223–4°. HI (d. 1.7) at 135–40° gives the *4-HO deriv.*, m. 264–5°. I, gradually added to *p*-$C_6H_4(OMe)_2$ at 50–5°, gives *2,5-dimethoxy-p-terphenyl*, m. 159–60°; *2,5-di-HO deriv.*, m. 173–4°. *p*-$C_6H_4(NAcNO)_2$ and *p*-$C_6H_4(OMe)_2$ give *2,5,2″,5″-tetramethoxy-p-terphenyl*, m. 159–60°. *2-Methoxy-N,N′-diacetyl-1,4-phenylenediamine*, m. 220–2°; N oxides in Ac_2O-AcOH-P_2O_5 at 8° give a yellow solid, considered the *5-NO_2 deriv.*, m. 258–9°. I (10 g.) and 800 cc. PhMe at 18° give 0.8 g. of 4-MeC_6H_4Ph (IV), m. 207–8°, 0.1 g. of the *3-Me isomer*, m. 169–70°, and 0.9 g. of the *2-Me isomer* (V), m. 91–2°. 4-$AcNHC_6H_4C_6H_4$-Me-2 gives a yellow oily NO deriv., which with C_6H_6 yields V. CrO_3 oxidation of V gives *2-methylbiphenyl-4′-carboxylic acid*, m. 173–5°. Similarly 4-Ac(NO)NC_6H_4-C_6H_4Me-4 with C_6H_6 gives IV. *p*-$C_6H_4(NAcNO)_2$ and *p*-$C_6H_4Me_2$ give *2,5,2″,5″-tetramethyl-p-terphenyl*, m. 112–13°. III.

Preparation and nitration of *m*-terphenyl *Ibid.* 1288–92.—3-Phenylcyclohexanone (18 g.) and PhMgBr, refluxed 1 hr. and dehydrated with 98% HCO_2H, give *1,3-diphenyl-3-cyclohexene* (and/or the Δ^2-isomer), b_{15} 198–200°; dehydrogenation with boiling quinoline contg. S for 36 hrs. gives 9 g. of *m*-terphenyl (I). The prepn. of 3-$O_2NC_6H_4Ph$ in 63% yield is given. 3-$AcNHC_6H_4Ph$ (10 g.) with N oxides in AcOH-Ac_2O-P_2O_5 gives an oily NO deriv., which with C_6H_6 gives 2.6 g. of I. I (5 g.) and HNO_3 in AcOH at 85–90° for 2–3 hrs. give 4.5 g. of the *4′-NO_2 deriv.* (II), pale yellow, b_{10} 280°; reduction with $SnCl_2$ in HCl gives the *4-NH_2 deriv.*, whose Ac deriv. m. 116–17° (cf. Wardner and Lowy, *C. A.* **26**, 3789). I and HNO_3 (d. 1.42) at 80–90° for 20 min. give a di-NO_2 deriv., m. 213–15° (W. and L. give 214°); some II is also formed. I and HNO_3 (d. 1.5) in AcOH, heated 1 hr. at 100°, give a tri-NO_2 deriv. (III), pale yellow, m. 199–200° (W. and L. give 204°); II with HNO_3 in AcOH at 30° and finally at 90° for 30 min. gives III. Oxidation of II with CrO_3 in AcOH gives 2-nitrobiphenyl-5-carboxylic acid (IV), m. 220–1° (W. and L. give 227°). 4-Nitro-*m*-acetotoluidide gives an oily NO compd. which with C_6H_6 at 35° gives *2-nitro-5-methylbiphenyl*, yellow, m. 86–7°; oxidation with CrO_3 gives IV. Oxidation of the di-NO_2 compd. gives *p*-$O_2NC_6H_4C_6H_4CO_2H$. Structures are suggested for the di- and tri-NO_2 derivs. C. J. West

Aromatic hydrocarbons. XXIII. Zinc dust fusion. A new method for the reduction of organic compounds. E. Clar *Ber.* **72B**, 1645–9(1939); cf. *C. A.* **30**, 8205⁹.—Zn dust even at low temps. (200–90°) often exerts a very strong reducing action when used in a flux of NaCl-$ZnCl_2$. It is well not to use perfectly dry $ZnCl_2$, as a little water favors the evolution of H. Quinones are completely reduced in a few min. The course of the reaction can generally be readily followed by the change in the characteristic colors of the solns. of the quinones in $ZnCl_2$ to those of the hydrocarbons. The yields of spectrally pure hydrocarbons are often as high as 90%. Occasionally bimol. products are formed; the products are easily sepd., after soln. of the melt in dil. HCl, by crystn. As in Zn dust distn., the new method, designated *Zn dust fusion* for convenience, does not remove aromatically bound ether O. The formation of bimol. products increases when dry $ZnCl_2$ and no NaCl are used; it may be as much as 25%. A few examples of the application of the method are given. When Ph_2CO is fused with 1 part NaCl, 5 parts $ZnCl_2$ and 1 part Zn dust and the temp. is raised within a few min. from 220° to 290°, Ph_2CH_2 distils over with moderate

foaming; the last portions are removed *in vacuo*, the residue is taken up in dil. HCl and the undissolved portion, after washing and drying, is sublimed *in vacuo* in CO_2, giving a little Ph_2C CPh_2, m. 221°. From anthraquinone are obtained about 0.8 part anthracene, m. 215°, and 0.1 part bianthryl, m. 310° (evacuated tubes). Phenanthrenequinone gives 0.8 part phenanthrene and 0.1 part *9,9'-biphenanthrylene 10,10'-oxide*, light yellow, m. 299°, slowly sol. in concd. H_2SO_4 with light-green color. From 3,4,8,9-dibenzopyrene-5,10-quinone is obtained more than 80% 3,4,8,9-dibenzopyrene, m. 308° (evacuated tubes). The 3,4,9,10-isomer, m. 280°, is obtained in about 85% yield from the 5,8-quinone. In the same way are obtained anthanthrene, m. 461° (evacuated tubes); violanthrene, m. above 360° (about 85%); *isoviolanthrene*, deep dark red, much darker than violanthrene, with the 1st absorption band in molten naphthalene at 5160 A.; and anthrazine (from indanthrene), vivid yellow.

C. A. R.

The appearance of color in adsorption on surface-active substances; analogy between the action of adsorption and complex formation (preliminary communication). Ernst Weitz and Fritz Schmidt. *Ber.* **72B**, 1740–2(1939).—The same colors which appear when triarylmethyl halides form "double salts" with various inorg. halides ($ZnCl_2$, $AlCl_3$) are produced when the halides in benzene or $CHCl_3$ are brought together with silica gel (ground, dried at about 200° and kept over P_2O_5) or, to a lesser extent, with surface-active Al_2O_3 ("for chromatographic adsorption analysis," Brockmann). When the soln. is poured or sucked off, according to the usual chromatographic technique, there remains an upper colored layer in which the solute is completely retained, while the colorless lower part of the column contains only solvent. On addn. of alc. or acetone, i. e., solvents in which complexes of triarylmethyl halides are incapable of existence, the color of the upper layer is destroyed and the components of the complex are eluted. The tetraaryl-*p*-xylylene dihalides behave in the same way; the tetra-Ph compd. gives an intensely yellow, the tetrabiphenylyl deriv. an intensely violet adsorbate. Here, too, silica gel works better than Al_2O_3, but talc and pptd. $CaCO_3$ also give some color. In the adsorption on silica gel it may be assumed that the adsorbed ("bound") part of the halide is not the halogen but the triarylmethyl residue. The peculiar action of adsorption is shown by an entirely different example. Tri- and di-arylamines behave like NH_4 radicals, adding monovalent acid residues, like ClO_4, to form intensely colored "ammium salts." While $(p\text{-}MeC_6H_4)_3N$ in benzene with Bz_2O_2 (the dimol. radical of BzOH) alone or with silica gel alone gives no color, an intense greenish blue color at once appears when it is brought together with Bz_2O_2 in the presence of silica gel. Ph_2NH, carbazole and *N*-methylcarbazole behave similarly. The last presumably forms the corresponding "ammonium" salt, but with the other 2 (secondary) amines possible oxidation to the tetraarylhydrazines may blot out the picture. These tetraarylhydrazines, like the triarylamines, also add acid residues to form deeply colored "hydrazinium" salts and give with anhyd. $AlCl_3$ or $ZnCl_2$ addn. products of the same color as the salts formed by oxidation, and the same colors as with $AlCl_3$ also appear when the hydrazines in benzene or CCl_4 are treated with dry silica gel (deep violet with the tetra-*p*-tolyl, blue-violet with the tetraanisyl compd.). On chromatographic adsorption on silica gel the $(NPh_2)_2$ forms a dark-green column; with benzene as solvent the color extends as far as the column has been wet, and as more benzene is added the color advances to the lower end of the column and finally there issues from the deep-green column an almost colorless soln. contg. much hydrazine. When benzene-benzine (about 1:1) or pure CCl_4 is used, a colorless zone (contg. only solvent) is observed below the colored zone. With the more strongly adsorbed tetraanisylhydrazine, this colorless zone is obtained with pure benzene also. Acetone in every case destroys the characteristic color of the adsorbate and elutes the hydrazine; the tetraphenyl- and tetratolylhydrazines are recovered almost quantitatively, but with the more easily disproportionated tetraanisylhydrazine only dianisylamine could be isolated in cryst. form after elution. Al_2O_3 gives a color (blue-violet) only with the tetraanisyl compd. C. A. R.

Phenolhomophthalein. Buu-Hoï. *Compt. rend.* **209**, 321–4(1939).—Dehydration of a mixt. of *homophthalic anhydride* and PhOH with $SnCl_4$ at 125° gives *3-p-hydroxyphenylisocoumarin*, m. 211°; *homophthalazone*, m. 243° (decompn.); *acetate*, m. 161°. W. J. Peterson

Reaction of unsaturated and polynuclear aromatic hydrocarbons with sodium and calcium in liquid ammonia. Walter Hückel and Horst Bretschneider. *Ann.* **540**, 147–89(1939).—Wooster and Smith (*C. A.* **25**, 944) state that $C_{10}H_8$ with Na in liquid NH_3 gives tetralin (I), whereas Schlenk and Bergmann (*C. A.* **22**, 4493), claim that the product is Δ^2-dihydronaphthalene (II). $C_{10}H_8$ (3 g.) in 75 cc. Et_2O, treated with 4.8 g. Na and then with about 150 cc. NH_3 at −75° to −65°, at first gives a green color, which changes to orange-red and then to red-orange or red; after about 20 min. the Na complex is decompd. with 6.5 g. MeOH, giving II; at higher temps. there results a mixt. of II and Δ^1-isomer (III); at the b. p. of NH_3 some III is formed. In 1 expt. nearly pure III resulted. II and Na in Et_2O-NH_3 at −60° give III. At −50° III is transformed by Na in NH_3 into I. Ca gives similar results. Ph_2 with Na or Ca in NH_3 at −75° to 70° gives the 3,4-dihydro deriv. (IV), b_{12} 114°; $EtNO_2$ in EtOH at −50°, followed by concd. HCl in EtOH, gives the nitrosochloride, characterized as nitrolpiperidide, 191°. IV with Na at −75° gives the 3,4,5,6-tetrahydro deriv., b. 125–6°. Terphenyl (V) (prepn. given) with Na in NH_3 gives a *3,4-dihydro deriv.*, (VI), m. 70°; the concd. H_2SO_4 soln. has a cinnabar-red color; there also results a *compd.* $C_{18}H_{14}$, m. 152–3°, which is isomeric with V but does not contain a reactive double bond; they are sepd. by crystn. from EtOH, hexahydrotoluene and petr. ether. Catalytic reduction of VI yields 4-cyclohexylbiphenyl. VI reacts easily with Na, giving a red compd., not further investigated. 1,4-Diphenylbutadiene reacts fairly easily with Na or Ca, giving a mixt. of liquid and solid hydrocarbons; apparently the 2 metals give different reaction products. Ph_2CH_2 gives a blue color with Ca and the product yields a small quantity of an unsatd. hydrocarbon. 9,10-Diphenylanthracene (VII) with Na in liquid NH_3 gives an orange or orange-red soln. but de compn. of the complex with NH_4Cl or alc. gives only VII. Phenanthrene reacts only partially with 2 atoms of Na or 1 atom of Ca in liquid NH_3 at −75°, giving an orange-red soln. and ppt.; the resulting product is, principally 1,2,3,4-tetrahydrophenanthrene, which probably is not the primary reaction product. Butadiene and Na in NH_3 give butene and octadiene. C. J. West

Molecular compounds of methyl α-naphthol ether and dinitro products. S. I. Burmistrov. *Trans. Inst. Chem. Tech. Ivanovo* (U. S. S. R.) No. 2, 14–17(1939). — Mol. compds. m. 57.5°, 71°, 96°, 66.0°, 66.5° and 124° were prepd., from α-methoxynaphthalene and 1,3-dinitrobenzene, 2,4-dinitrotoluene, 2,4-dinitrophenol, 2,4-dinitroanisole, 2,4-dinitrochlorobenzene and 3,5-dinitro-4-chlorobenzoic acid by pptg. from a cold alc. soln. The compds. were sufficiently stable, they varied in color from bright yellow to red, and had a sharp m. p. It is suggested that they may be used in the identification of dinitro compds. B. Z. Kamich

Condensation of diarylcarbinols with naphthol ethers. S. I. Burmistrov. *Trans. Inst. Chem. Tech. Ivanovo* (U. S. S. R.) No. 2, 17–20(1939).—Condensation of (1) benzohydrol + α-methoxynaphthalene, (2) phenyl-*p*-xenylcarbinol + α-methoxynaphthalene, (3) phenyl-*p*-xenylcarbinol + α-ethoxynaphthalene, (4) benzohydrol + ethoxynaphthalene, (5) phenyl-*p*-tolylcarbinol + methoxynaphthalene, (6) phenyl-α-naphthylcarbinol + α-ethoxynaphthalene, and 6') di-*p*-xenylcarbinol + α-ethoxynaphthalene gave the following *naphthylmethanes*, resp.: (1) diphenyl-α-methoxy, m. 151°, (2) phenyl-*p*-xenyl-α-methoxy, m. 155°, (3) phenyl-*p*-xenyl-α-ethoxy), m. 163–5°, (4) diphenyl-α-ethoxy, m. 159.5°, (5) phenyl-*p*-tolyl-α-methoxy, m. 132.5°, (6) phenyl(di-α-methoxy),

m. 161–2°, and (7) di-*p*-xenyl-α-ethoxy, m. 114–6°.
B. Z. Kamich

Constituents of natural phenolic resins. XVI. Route to the synthesis of lignandiols. Robert D. Haworth and David Woodcock. *J. Chem. Soc.* **1939**, 1237-41; cf. *C. A.* **33**, 6833[2].—This is a continuation of the work on the synthesis of lignandiols reported in *C. A.* **32**, 5488[2]. 1-Phenylnaphthalene-2,3-dicarboxylic anhydride (I) (26.2 g.) in 600 cc. hot H_2O contg. 10 g. NaOH, treated with 1200 g. 4% Na-Hg and the stirred mixt. heated on the water bath and CO_2 passed in for 12 hrs., gives 27.5 g. of crude 1-phenyl-1,2,3,4-tetrahydronaphthalene-2,3-dicarboxylic acid (II), m. 170-80°; only after repeated crystn. from Me_2CO could a homogeneous acid (III), m. 209°, be obtained. Heating III with 15 parts of AcCl gives 90% of the anhydride (IV), m. 155-6°. Unlike I, IV with cold conc'd. H_2SO_4 is sulfonated and does not yield a ketone acid. Alk. hydrolysis of IV does not give III but an *isomer*, m. 219°. Esterification of II with alc. HCl, 10% alc. H_2SO_4 or refluxing the dry Ag salt with 3 parts alkyl iodide for 6 hrs. gives the *Me ester*, m. 106.9°; distn. of this form or esterification with HCl for 12 hrs. gives a liquid Me ester, b_1 190-5°; *Et ester* (V), $b_{1.5}$ 210–15°. *6,7-Dimethoxy-1-(3',4'-dimethoxyphenyl)-1,2,-3,4-tetrahydronaphthalene-2,3-dicarboxylic acid* (VI) is obtained in a crude yield of 90%, m. 140–55°; wasteful crystn. gives a pure VI, m. 155–8°. VI yields a *Me ester*, m. 146°, from the Ag salt and MeI in 80% yield, or with 1 mole MeOH, m. 110°, on esterification with HCl or H_2SO_4; EtOH-H_2SO_4 gives 20% of the *Et ester* (VII), m. 116–17° (from MeOH), and 50% of an oil, b_3 270–5°; *Et II ester*, m. 122°. *6,7-Methylenedioxy-1-(3',4'-methylenedioxyphenyl)-1,2,3,4-tetrahydronaphthalene-2,3-dicarboxylic acid* could not be obtained in a homogeneous modification; *Et ester* (VIII), $b_{1.5}$ 260–5°. Addn. of 6.2 g. of V in 10 cc. abs. EtOH to 3.76 g. of Na at 180° and after 0.5 hr. addn. of 3 cc. EtOH at 15-min. intervals for 1 hr. give 1.5 g. of *1-phenyl-2,3-di(hydroxymethyl)-1,2,3,4-tetrahydronaphthalene* (IX), which did not crystallize; heating the oil with $KHSO_4$ at 180° for 0.5 hr. gives the *anhydro deriv.* (X), $b_{1.5}$ 180°, m. 85.8°; repeated crystn. gives a form m. 103.4°. Reduction of VII gives 40% of an oil, 10% of which seps. from an Et_2O soln.; repeated crystn. from MeOH-Et_2O gives 5% of the *1-(3',4'-dimethoxyphenyl) analog* (XI) of IX, m. 155.8°; the *anhydro deriv.* m. 126.7°; dehydrogenation with $Pb(OAc)_4$ in AcOH at 70° for 1.5 hrs. gives dehydroanhydrolariciresinol di-Me ether (XII) (*C. A.* **32**, 5488[2]); the Et_2O mother liquor from XI on evapn., dehydration and dehydrogenation gives 40% of XII. X was not dehydrogenated by $Pb(OAc)_4$ and it is possible that the action depends upon the activating influence of MeO groups upon the CH_2 groups adjoining the aromatic nuclei. VIII on reduction with Na and EtOH gives 37% of an oil, from which was isolated 5% of *6,7-methylenedioxy-1-(3',4'-methylenedioxyphenyl)-2,3-di(hydroxymethyl)-1,2,3,4-tetrahydronaphthalene*, m. 183.4°; the *anhydro deriv.* m. 137°. Since the configuration of these acids is modified by esterification in the presence of hydrions, further configurational change under the conditions of the Bouveault-Blanc reduction was anticipated. This has been confirmed by expts. on bis(3,4-dimethoxybenzyl)succinic acid, which exists in 4 modifications (*C. A.* **33**, 2587[3]). Using the Ag salt method, there were prepd. the *meso-Me ester*, m. 136–7°, and the *meso-Et ester*, m. 114–15°; the *dl-Me ester*, m. 65.6° and the *dl-Et ester*, an oil; and the *d-* and *l-Et esters*, m. 65–6°, $[\alpha]_D^{25}$ 26.4° and −26.2°. Reduction of these esters in EtOH with Na at 180° gives *α,δ-bis-(3,4-dimethoxyphenyl)-β,γ-di(hydroxymethyl)-butane* (XIII), an oil distg. unchanged at 2 mm.; it is optically inactive; *diformyl deriv.*, m. 131.2°; *anhydro deriv.*, m. 118–19°; oxidation of XIII gives *dl*-matairesinol di-Me ether. The ester which escapes reduction undergoes stereochem. change and the acidic products recovered from the reduction of the *meso-* and *dl*-forms of the ester contain approx. 35 and 15% of the meso form of the acid.
C. J. West

A derivative of vitamin K_1. H. J. Almquist and A. A. Klose. *J. Biol. Chem.* **130**, 791–3(1939); cf. *C. A.* **33**, 5899[8].—During the alk. hydrolysis of vitamin K_1 no appreciable portion is split off but there is an increase in mol. wt. and a change in the analysis which suggests an addn. of 2 O atoms and perhaps several H atoms. At least 1 of these O atoms is phenolic. The fact that there is no appreciable splitting indicates that the side structure attached to the recognized 1,4-naphthoquinone nucleus is held by a C-to-C bond. The phytyl group is such a logical choice for this side structure that elaborate arguments in its favor seem unnecessary. Several very active preps. of 2-methyl-3-phytyl-1,4-naphthoquinone have been obtained and this compd. is probably identical with vitamin K_1. The purest preps. have shown approx. the same degree of activity as vitamin K_1.
A. P. L.

Indones. XVI. The partial dehalogenation of two α-ethyl-α-chloro-β-phenyl-β-chlorohydrindones. Remo De Faci and Francesco Pirrone. *Gazz. chim. ital.* **69**, 166–71 (1939); cf. *C. A.* **31**, 8531[3].—The partial dehalogenation of an α-methylchloro-β-phenylchlorohydrindone and formation for the 1st time of compds. with a single Cl atom on a cyclostatic double bond adjacent to a CO group (cf. *C. A.* **31**, 6649[4]) made it of interest to learn whether the new reaction holds true also of the α-ethyl-chloro-β-phenylchlorohydrindone (I) which m. 94–6°, and of (II) which m. 115–16°, both of which have been described (cf. *C. A.* **24**, 3779; **26**, 4043; **31**, 8531[3]). Dehalogenation of I was carried out by Cu, $AgNO_3$ and KI at room temp. and in boiling EtOH, and by NH_3 at 0° and at room temp. I in abs. EtOH and Cu turnings allowed to stand in darkness for 20 days, and the decanted soln. evapd. in darkness, yield $C_{17}H_{14}OCl$ (III), m. 145–6°, already prepd. otherwise (*C. A.* **24**, 3779); it does not react with $AgNO_3$ in acetone and does not liberate I from alc. KI; with conc'd. H_2SO_4 it gives a red color with intense green fluorescence; with 90% Cl_3CCO_2H it gives a yellow color with green fluorescence (intensified by heating). I in abs. EtOH and Cu turnings, refluxed for 45 min., and the filtered soln. evapd., yield a *compd.*, $C_{17}H_{14}OCl$ (IV), lustrous, m. 105.6°, and a *compd.*, $C_{17}H_{14}OCl$ (V), lustrous, m. 127.8°. Neither IV nor V liberates I from alc. KI, or forms AgCl from $AgNO_3$ in acetone. I in abs. EtOH and $AgNO_3$, maintained at room temp. in darkness for 10 days, or refluxed for 1 hr., and the filtered soln. evapd., yield only III. I in EtOH and KI maintained in darkness at room temp. for 10 days, the brown-red soln. decolorized by $Na_2S_2O_3$, and poured into water, yield III and IV. I in EtOH and KI, refluxed for ½ hr. (the soln. turns yellow, then brown-red), decolorized by $Na_2S_2O_3$, and dild. with water, yield IV. A 2% soln. of I in EtOH at 0°, satd. with NH_3, yields III. Dehalogenation of II was carried out only in boiling EtOH with Cu and KI. II in abs. EtOH and Cu turnings refluxed for 45 min. (the soln. turns yellow), and the filtered soln. evapd., yield V. A 2% soln. of II in EtOH and KI, refluxed for 1 hr., the brown-red soln. decolorized by $Na_2S_2O_3$ and dild., yield IV and α-ethyl-β-phenylindone (VI). In some cases, by repeated crystn. crystals with different m. ps. from those of III, IV or V were obtained. Neither the mono-Cl deriv. of VI which m. 132–3° nor that which m. 119.20° was obtained in any expt. The position of the Cl atom in III, IV and V was not established.
C. C. Davis

Synthesis of a high-molecular hydroxymethylfurfural derivative. Tosinori Iseki and Tukouru Sugiura. *J. Biochem.* (Japan) **30**, 113–18(1939).—Bis(furfural-2-methyl) ether, which can be easily obtained by warming hydroxymethylfurfural, is changed in the body and eliminated in the urine as bis(carboxyfuran-2-methyl) ether. This substance can also be prepd. from the former by treating with NaOH and NH_3-$AgNO_3$. The bis-(carboxyfuran-2-methyl) ether is converted to the acid chloride, dissolved in pyridine and poured into water. A yellowish substance seps. which solidifies on washing. The substance is a tetrabis(pyromucic acid anhydride-2-methyl) ether.
S. Morgulis

Sugar-amino acid compounds. Tosinori Iseki and Tukouru Sugiura. *J. Biochem.* (Japan) **30**, 119–23

(1939).—Several products were prepd. by condensation of hydroxymethylfurfural with Ni compds. The structural formulas and m. ps. are tabulated, and detailed descriptions of each prepn. are given. S. Morgulis

Isonitrosopyrroles. XI. Transformations of 3-nitroso-2,5-dimethylpyrrole. Tommaso Ajello and Sigismondo Cusmano. *Gazz. chim. ital.* **69**, 207–14(1939); cf. *C. A.* **32**, 4557⁷.—Earlier expts. on the action of acids on β-isonitrosopyrroles (cf. A., *loc. cit.*) showed the influence of aromatic substituents in the formation of isoxazoles from β-isonitrosopyrroles by the action of acids. The present work represents the first study of the influence of aliphatic substituents; a method of prepn. of 2,5-dimethylpyrrole (I) superior to that of Paal (*Ber.* **18**, 2251(1885)) or of Knorr (*Ann.* **236**, 310(1886)) was developed. Acetonylacetone (30 g.), NH_4OAc (40 g.) and glacial AcOH (100 g.) heated on a steam bath for 50 min., boiled for 10 min., poured into excess NH_4OH, extd. with Et_2O, the ext. washed, and dried by Na_2SO_4, yields 20 g. (80%) of I. A soln. of Na (slightly more than 1 g.-equiv.) in abs. EtOH poured onto I, $AmNO_2$ (1 g.-mol.) added (cooling), allowed to stand for 12 hrs., dild. with Et_2O, allowed to stand, decanted from the brown-yellow ppt. and the latter washed with Et_2O, yields N.CMe.C(NONa).CH.C(Me) (II). H_2SO_4 (30%) added to hot aq. II until acidic (the liquid turns orange-red then wine-red), allowed to stand, satd. with NH_4Cl, and extd. with Et_2O, yields MeC(CH.CAc.NO) (III), (cf. Angelico, *Gazz. chim. ital.* **34**, 38(1904)). It is also formed by refluxing MeC(NOH)CH_2C(NOH)C(NOH)Me with 10% aq. HCl, steam-distg., satg. the distillate with $(NH_4)_2SO_4$ and extg. with Et_2O. III does not react with $FeCl_3$, Fehling soln. or NH_3-$AgNO_3$. With I and an alk. carbonate it forms CHI_3. When distd., aq. II yields NH_3 and a liquid distillate which, extd. with Et_2O, yields III. Concd. alc. III and concd. aq. $NH_2OH.HCl$ refluxed for 2 hrs., poured into water, extd. with Et_2O, the residue evapd. and purified by C_6H_6, yield the *oxime*, $C_8H_8O_2N_2$ (IV), m. 117°. IV treated by the Schotten-Baumann method, the product washed with water, dil. H_2SO_4, dil. NH_4OH and water, and purified by C_6H_6, yields the *Bz deriv.*, $C_{13}H_{12}O_3N_2$, m. 180 1°. Alc. III and $PhHNNH_2$ in 50% AcOH, heated for a few min., yield, on standing, the phenylhydrazone, m. 167° (cf. Schmidt and Widmann, *C. A.* **3**, 2310). Alc. III and excess aq. semicarbazide-HCl, boiled for several min., yield the *semicarbazone*, $C_7H_{10}O_2N_4$, lustrous, m. 238–9° (decompn.). Alc. III and aq. $H_2NNH_2.HCl$ heated for several min., more EtOH added, allowed to stand for several hrs., the ppts. washed with water and purified by EtOH, yield the *azine*, $C_{12}H_{14}O_2N_4$, m. 157–8°. Its aq. soln. is yellow, and from it crystallizes a yellow form, which turns white at 120 5°. In conjunction with the earlier expts., the work shows that the reaction of isonitrosopyrroles with acids is a simple hydrolytic process, and also shows that the aliphatic pyrrole, I, is less stable than its phenylated homologs. C. C. Davis

Sulfur analogs of furan types. Arthur L. Jacoby. *Iowa State Coll. J. Sci.* **13**, 70–2(1938); cf. Fabinyi and Szeki, *C. A.* **3**, 1911. Dibenzothiophene was taken as the starting compd. The compds. reported and their consts. include: *2-acetyldibenzothiophene*, m. 111°; *Me dibenzothiophene-2-carboxylate*, m. 74–5°; *dibenzothiophene-4-carboxylic acid*, m. 252–3°; its *Me ester*, m. 95°; a monoacetoxymercuri deriv. of dibenzothiophene, m. 215°; *4-hydroxydibenzothiophene*, m. 167°; a dinitro deriv. of the last-named compd., m. 204°; 4-methoxydibenzothiophene, m. 123°; *4-aminodibenzothiophene*, m. 110°, and its Ac deriv., m. 198°; *1-bromo-4-acetaminodibenzothiophene*, m. 254°; *2-acetaminodibenzothiophene*, m. 178°; a nitroacetamino compd. from the nitration of 2-acetaminodibenzothiophene, m. 209°; a *nitroaminodibenzothiophene*, m. 248–50°; *β-2-dibenzothenoylpropionic acid*, m. 150.5–162°; *γ-2-dibenzothienylbutyric acid*, m. 131°; *1-keto-1,2,3,4-tetrahydrothiobrazan*, m. 178°; and *o-2-dibenzothenoylbenzoic acid* (*unstable hydrate*, m. 120–5°; *Et ester*, m. 105–7°). Dibenzothiophene is best prepd. by heating biphenyl with S in the presence of $AlCl_3$. It reacts with Na in liquid NH_3 to give a dihydro deriv., m. 76°, and a picrate, m. 165°. F. E. Brown

Preparation of certain trimethyleneindole derivatives. R. Gordon Gould, Jr., and Walter A. Jacobs. *J. Biol. Chem.* **130**, 407–14(1939).—3-Amino-1-naphthoic acid sulfate was converted to the *nitrate* (I), m. 225–30° (decompn.); free *Me ester*, m. 72–3° (*Ac deriv.*, m. 136–7°); free *Et ester*, $B_{0.5}$ 170–5° (*Ac deriv.*, m. 175–6°; *HCl salt*, m. 193–4° (decompn.)). Nitration of I gave a mixt. of orange *3-amino-8-nitro-1-naphthoic acid* (II), m. 230–1° (decompn.) (*Ac deriv.*, m. 274–6° (decompn.)), and red *3-amino-5(?)-nitro-1-naphthoic acid* (III), m. 203–8° (decompn.). II on reduction and lactamization gave *3-aminonaphthostyril* (IV), m. 238–40°; *picrate*, m. 245–50° (decompn.); *Ac deriv.*, m. 300–2° (decompn.). Reduction of III gave the *diamino deriv.*; *di-HCl salt*, m. 305–8° (decompn.), *di-Ac deriv.*, m. 323–30° (decompn.). Reduction of IV by Na in BuOH gave *β-amino-3,4-trimethyleneindole*; *picrate*, m. 242–8° (decompn.); *HCl salt*, m. 215–22° (decompn.). Naphthalene-1,4-dicarboxylic acid was nitrated, giving the *5-nitro deriv.*, m. 270–4° (decompn.), which on reduction and lactamization gave *naphthostyril-4-carboxylic acid* (V); *Me ester*, m. 260–1°; *Et ester* (VI), m. 217–18°. Reduction of the NH_4 salt of V by Na in BuOH gave *3,4-trimethyleneindole-γ-carboxylic acid*, m. 142–4°; *picrate*, m. 168–70° (decompn.); *Me ester*, m. 82–4°. Similar reduction of VI gave *γ-hydroxymethylene-3,4-trimethyleneindole*; *picrate*, m. 147–50° (decompn.). Catalytic hydrogenation of VI gave *Et 1,2,3,4-tetrahydronaphthostyril-4-carboxylate* which on saponn., then addn. of HCl, gave *1,2,3,4-tetrahydro-8-aminonaphthalene-1,4-dicarboxylic acid-HCl*, m. 300 9° (decompn.). D. S. Searle

Action of hydrazine hydrate on derivatives of organic acids. M. Freri. *Atti X° congr. intern. chim.* **3**, 150–4 (1939).—The action of $H_2NNH_2.H_2O$ (I) on dimethylacrylic (II), angelic (III), tiglic (IV) and various substituted cinnamic acids was studied in connection with the prosecution of other work. The esters of II gave transparent resins contg. free I, the formation of which was in accordance with the behavior of vinyl derivs. in the presence of alkali. Condensation of 1.1 g. of III Me ester with 0.5 g. I in boiling alc. gave a dimethylpyrazolone, $C_5H_8N_2O$, m. 268°, whereas a similar condensation of IV Me ester gave a viscous product from which the pyrazolone was crystd. out with difficulty. Tiglyl chloride reacted with I to give the sym. dihydrazine, $C_{10}H_{16}N_2O_2$, m. 182–3°. The behavior of the isomeric acids, III and IV, is parallel to that of the crotonic acids; the malenoid form is most capable of pyrazolone ring formation. Of the cinnamic acids the behavior of *p*-nitrocinnamic acid is most interesting. With I, the Et ester gave a *compd.* (V), m. 147°, to which a second mol. of $H_2N.NH_2$ is added to the double bond. Hydrolysis of V with boiling HCl gave the hydrazide HCl salt, $C_9H_9N_3O_3.HCl$, m. 203°. Anisaldehyde, vanillin and piperonal condensed with I to give *products*, m. 198°, 180° and 217°, resp. Boiling 4.2 g. $Ph(EtO)C.CHCO_2Et$ for 2 hrs. with 1.2 g. I in 20 cc. abs. alc. gave golden-yellow crystals of an *addn. product*, $C_{13}H_{20}N_2O_3$, m. 156°, decompd. by HCl with liberation of $H_2NNH_2.2HCl$. C. R. Addinall

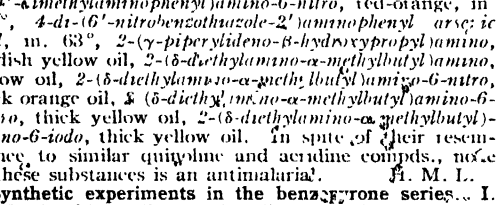
Action of organomagnesium mixtures on the phenylhydrazones of cyclanones. Panos Grammaticakis. *Compt. rend.* **209**, 317–19(1939); cf. *C. A.* **33**, 7285⁶, 7285⁸.—*PhMgBr* (I) reacts with *cyclohexanone phenylhydrazone* to give some *1,2,3,4-tetrahydrocarbazole*, B_{10} 190°, m. 120°, but mostly *β-(1-phenylcyclohexyl)-phenylhydrazine* (II), m. 113°; *HCl salt*, m. 215° (decompn.); *oxalate*, m. 186°; *phenylureide*, m. 172°. II, in Et_2O or alc. soln. oxidizes in the air to give the corresponding *azo compd.*, m. 60°. I reacts with *2-methylcyclohexanone phenylhydrazone* to give some *1-methyl-1,2,3,4-tetrahydrocarbazole* and *5-methyl-1,2,3,4-tetrahydrocarbazole*, but mostly a compd. $C_{18}H_{21}N$, m. 102°; *HCl salt*, m. 258°; *oxalate*, m. 165°; *acetate*, m. 93°; *phenylureide*, m. 168°. I, *EtMgBr* and *$PhCH_2$*-

MgCl, each react with *3-methylcyclohexanone phenylhydrazone* to give *2-methyl-1,2,3,4-tetrahydrocarbazole*, beside other products. I reacts with *cyclopentanone phenylhydrazone* to give *2,3-trimethyleneindole*, m. 109°, b_1 160-2°. W. J. Peterson

Action of ammonia upon several 3-substituted 1,5-dibromopentanes. Miho Piantanida. *J. prakt. Chem.* **153**, 257-62(1939).—4-(Diphenylmethylene)tetrahydropyran (5.7 g.) on catalytic reduction gives 2 g. of *4-(diphenylmethyl)tetrahydropyran* (I), m. 138°. 4-Isopropyltetrahydropyran (2 g.) and 40 g. 70% HBr, heated 6 hrs. at 100-10°, give 83% of *3-isopropyl-1,5-dibromopentane* (II), b_{10} 128-30°. 4-(Diethylmethyl)tetrahydropyran gives 78% of *3-diethylmethyl-1,5-dibromopentane* (III), b_{23} 178-80°, b_{18} 157-9°; I gives 70% of *3-diphenylmethyl-1,5-dibromopentane* (IV), m. 82°. II (2.5 g.) and 25 cc. 20% MeOH-NH_3, heated at 130-40° for 4 hrs., give 26% of *4-isopropylpiperidine*, b_{10} 62-4° (*picrate*, yellow, m. 154°; *chloroplatinate*, orange-yellow, m. 180° (decompn.)), and 23% of *4,4'-diisopropylbispiperidiniumspiran bromide* (V), decomp. about 280°; III similarly gives 29% of *4-diethylmethylpiperidine*, b_2 71° (*picrate*, yellow, m. 150.5°; *chloroplatinate*, orange-yellow, decomp. 180°), and 32% of the *diethylmethyl analog* of V, decomp. about 300°. IV similarly gives 36% of *4-diphenylmethylpiperidine*, m. 99° (*picrate*, yellow, m. 150° (decompn.); *chloroplatinate*, orange-yellow leaflets), and 38% of the *diphenylmethyl analog* of V, decomp. above 300°. C. J. West

Absorption spectra of some sulfur compounds. R. A. Morton and A. L. Stubbs. *J. Chem. Soc.* **1939**, 1321-4.—Ultraviolet absorption spectra distinguish between the structures *o*-C_6H_4.S.C(:S).NR (I) and *o*-C_6H_4S.C(SR):N (II) and when R is H the structure corresponds to I rather than II and thus it is a thio ketone. The absorption spectrum of compd. *o*-C_6H_4CMe:CH.C(:S).NH or *o*-C_6H_4.CMe:CH.C(SR):N (III) (R = H) differs widely from those of the alkyl derivs. possessing the structure III (R = Me, Et, iso-Pr) and thus it must be a thio ketone if the ethers can be proved to be substituted thiolquinolines. Comparisons with the spectra of *o*-hydroxycarbanil, 1-hydroxybenzothiazole derivs. and substituted quinolines and quinolones support the interpretation. 2-Thiol-4-methylquinoline and Me_2SO_4 in 10% aq. NaOH give the *2-methylthio deriv.*, b_{14} 170-7°, m. 87°; *Et analog*, b_{14} 170-5°; *2-iso-Pr analog*, b_{12} 160-3°. C. J. West

Polarization in heterocyclic rings with aromatic character. V. Substitution reactions in phenylated heterocyclic rings. Eiji Ochiai, Toyo Kakuda, Iwao Nakayama and Giiti Masuda. *J. Pharm. Soc. Japan* **59**, 462-70 (1939); cf. *C. A.* **33**, 4988⁹.—Thioformamide (30 g.) when treated with 80 g. MeCHBrCOPh in the cold gave 4-phenyl-5-methylthiazole (I), b_2 110-11°; HCl salt m. 172°; HBr salt m. 197°; picrate m. 124-5°. Nitration of 2.5 g. I in the cold with fuming HNO_3 gave 2.8 g. 4-*p*-nitrophenyl-5-methylthiazole (II), $C_{10}H_8N_2SO_2$, m. 98°. Nitration of 5 g. 4-phenylthiazole with fuming HNO_3 gave 4-*p*-nitrophenylthiazole (III), $C_9H_6N_2SO_2$, m. 180° (yield 96%). Catalytic reduction of 0.1 g. III gave a small amt. of 4-*p*-aminophenylthiazole, $C_9H_8N_2S$, m. 99°; HCl salt, decomp. 270-5°; 4-*p*-acetylaminophenylthiazole, m. 165°. Catalytic reduction of II gave 4-*p*-aminophenyl-5-methylthiazole, $C_{10}H_{10}N_2S$, m. 80°; 4-*p*-acetylaminophenyl-5-thiazole, m. 144°. PhCHClCOPh (12 g.) when treated with 5 g. thioacetamide on the water bath for 2 hrs. gave 2-methyl-4,5-diphenylthiazole (IV), $C_{16}H_{13}NS$, m. 51-2°, sol. in ether; picrate, m. 123°. Nitration of 5 g. IV gave 2-methyl-4,5-di-*p*-nitrophenylthiazole, $C_{16}H_{11}N_3S(NO_2)_2$, m. 183°. Oxidation of the above compd. with $KMnO_4$ in alk. soln. gave *p*-nitrobenzoic acid, m. 233°. Nitration of 2,5-diphenylpyrazine gave a compd. (V), $C_{16}H_{10}O_4N_4$, m. 172-3°, and a compd. (VI), $C_{16}H_{10}O_4N_4$, m. 292°. Oxidation of V with $KMnO_4$ in alk. soln. gave the original compd. ω-Chloro-*m*-nitroacetophenone and diphenylpyrazine gave 2,5-di-*m*-nitrophenylpyrazine, $C_{16}H_{10}N_2O_4$, m. 249°. Nitration of 2-phenyl-4,6-dimethylpyrimidine at room temp. gave a mononitro deriv., $C_{12}H_{11}O_2N_3$, m. 155-6°, which on catalytic reduction gave an amino deriv., m. 88-90°; picrate, decompg. 199-200°; acetate, m. 130-2°. The above amino deriv. (m. 88-90°) gave through the diazotization reaction hydroxy-2-phenyl-4,6-dimethylpyrimidine, $C_{12}H_{12}ON_2$, m. 125-7°. 2-Phenyl-4,6-dimethylpyrimidine (1 g.), 2 g. BzH and 0.5 g. $ZnCl_2$ when heated in the sealed tube at 170° for 6 hrs. gave 0.7 g. 2-phenyl-4,6-distyrylpyrimidine, $C_{28}H_{20}N_2$, m. 158.5-9°. VI. **Polarization in the thiazole ring.** 2. Huzio Nagazawa *Ibid.* 471-7.—Bromination of 2-amino-4-methylthiazole (I) (1 g.) in 20% H_2SO_4 with Br gave 0.8 g. 2-amino-4-methyl-5-bromothiazole (II), $C_4H_5N_2SBr$, decompg. 105-8.5°; picrate, decomp. 196°. Bromination of I in $CHCl_3$ with Pr also gave II. Bromination of 0.6 g. 2-hydroxy-4-methylthiazole (III) with Br gave 0.35 g. 2-hydroxy-4-methyl-5-bromothiazole, C_4H_4ONSBr, decompg. 147.5°. In these reactions the bromination takes place at C atom 5 in the thiazole ring. Bromination of 4-methylthiazole in the manner described above failed to give a Br deriv. Attempts to prep. an I deriv. of 2-hydroxy-4-methylthiazole failed. III (4 g.) in ale. and 11 g. AgOAc in aq. AcOH when treated at room temp. for 4 hrs. gave a white ppt. The ppt. when acidified with AcOH and shaken with NaCl soln. for 5 hrs. gave a compd. which on bromination gave a Br deriv., m. 151° (probably 4-methyl-2,5-dibromothiazole). Acetylation of III gave 2-hydroxy-4-methyl-5-acetylthiazole, $C_6H_7O_2NS$, m. 210.5°, sol. in water, ale and MeOH while warm; semicarbazone, decompg. 244°. I when subjected to the Friedel-Crafts reaction gave 0.3 g. 2-acetamino-4-methylthiazole (IV), m. 134°. IV, 2-mercapto-4-methylthiazole and 4-methylthiazole when subjected to the Friedel-Crafts reaction all gave the original compd. III (2 g.) when subjected to the Gattermann reaction gave 0.4 g. 2-hydroxy-4-methylthiazole-5-aldehyde (V), $C_5H_5O_2NS$, decompg. 248°; *p*-nitrophenylhydrazone, decomp. 297-300°. 4-Methylthiazole, however, failed to react. III when subjected to the Reimer-Tiemann reaction also gave V. F. I. Nakamura



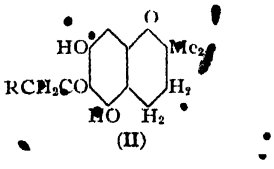
Action of nitric acid on phenacylacetone. S. Cusmano. *Atti X° congr. intern. chim.* **3**, 110-19(1939); cf. *C. A.* **33**, 3792⁶⁷.—Under stated conditions HNO_3 (d. 1.40) transforms phenacylacetone (I) into 3 different substances. I (5 g.) was added to 50 g. of HNO_3 (d. 1.40) and the slightly warm reddish brown soln. was heated on the steam bath for 1-2 min. The reaction mixt. was poured into H_2O and extd. with Et_2O. The washed and dried ext. was evapd. down and the residue was taken up in ale. The soln. was treated with 10% NaOH, dild. and extd. with Et_2O. Dstn. of the ext. with H_2O gave a residue (II), m. 105° (on recrystn. from ale.) and, on evapn., a mixt. of a small amt. of II and heavy prismatic crystals of another product (III), m. 50°. Repetition of the reaction with HNO_3 (d. 1.38) gave a larger yield of III. II is α-phenyl-γ-acetylisoxazole, $C_{11}H_9NO_2$ (*C. A.* **32**, 3557⁶); *oxime*, m. 170°; *Bz deriv.*, m. 158°, was identical with a sample of the known substance. From the structure of I it seemed probable that II and III might be isomeric. III, *α-methyl-γ benzoylisoxazole*, $C_{11}H_9NO_2$ (*phenylhydrazone*, m. 103-5°), was treated with $HONH_2.HCl$ in an equiv. amt. of Na_2CO_3, pptd. with H_2O, made alk. with Na_2CO_3 and extd. with Et_2O. Crystn. of the residue on evapn. from benzene or petroleum ether gave a *furazan oxime* (IV), $C_{11}H_{11}N_3O_2$, m. 110° (*Bz deriv.*, m. 101°), hydrolyzed by boiling for 5 mins. in 25% H_2SO_4 to *phenylacetonylfurazon*, $C_{11}H_{10}N_2O_2$, m. 93° (*p-nitrophenylhydrazone*, m. 158-60°). The alk. mother liquor was acidified and extd. with Et_2O, producing an *isoxazole oxime* (V), $C_{11}H_{10}N_2O_2$, m. 133° (*Bz deriv.*, m. 118-20°), hydrolyzed by boiling with dil. H_2SO_4 for 1 hr. to III. Structural formulas are assigned to II, III, IV and V on the basis of the above transformations. The alk. mother liquor from the separation of the 2 keto isoxazoles was acidified and extd. with Et_2O. The cryst. product was recrystd. from benzene

and gave white needles of *α-phenylisoxazole-γ-carboxylic acid*, $C_{10}H_7NO_3$, m. 162°, converted into cyanoacetophenone, C_8H_7NO, m. 81°, by decarboxylation at about 200°. C. R. Addinall

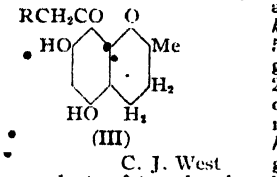
The action of nitric acid on phenacylacetone. II. Sigismondo Cusmano. *Gazz. chim. ital.* **69**, 214–21 (1939); cf. preceding abstr.—Angeli (*Gazz. chim. ital.* **22**, ii, 328(1892)) reported that by refluxing HNO_3 (d. 1.45) and $BzCH_2CH_2Ac$ (I) for 2 hrs., a compd. $C_{22}H_{18}O_{11}N_4$, m. 210° and insol. in alkalies, is formed. However, by following the procedure of A., the *compd.*, $C_{10}H_8O_6N_2$ (II), m. 210° (decompn.), was obtained. It was sol. in alkalies and was reppd. by acidification. Its aq. suspension liberates I from aq. KI-KIO_3. When fused it decomps. with liberation of CO_2. II, concd. H_2SO_4 and abs. EtOH, refluxed for 10 min., poured into water, neutralized with $NaHCO_3$, made alk. with KOH (the soln. turns brown-red), and the suspended product extd. with Et_2O, yield the *Et ester* (III), $C_{12}H_{10}O_6N_2$, of II, m. 183°, insol. in dil. aq. KOH. It is sapond. to II by heating in EtOH with dil. KOH. $BzCH_2CHAcCO_2Et$ (IV) and excess HNO_3 (d. 1.45), heated at 50° for 15 min. and poured into water, ppts. a *compd.*, $C_{12}H_{10}O_5N_2$ (V), yellowish, m. 183°. It is sapond. in hot EtOH by KOH to II. When IV and HNO_3 are heated thus for 2 hrs., a high yield of II is obtained directly. A hot mixt. of alc. II and $PhHNNH_2$ ppt. the *phenylhydrazine salt*, $C_{16}H_{14}O_5N_4$, of II, yellow, m. 168–70° (decompn.); insol. in aq. alkalies. It is hydrolyzed to II. Aq. 2% $KMnO_4$ added to II in 2% aq. KOH at 100° until permanently violet-red, acidified with H_2SO_4 and extd. with Et_2O yields *p*-$O_2NC_6H_4CO_2H$. $PhCH{:}CHAcC(CO_2Et){:}NO$ (cf. C. and Massara, *C. A.* **33**, 3792[1]), and HNO_3 (d. 1.45), heated at 50° until a clear soln. is obtained and poured into water, ppt. III. A consideration of the results in conjunction with the earlier work makes it certain that II is *α-p-nitrophenyl-γ-isoxazolecarboxylic acid*, *p*-O_2N-$C_6H_4C{:}CH.C(CO_2H){:}NO$. C. C. Davis

Benzothiazole compounds. III. Some derivatives of 2-aminobenzothiazole. N. S. Drozdov and V. I. Stavrovskaya. *J. Gen. Chem.* (U. S. S. R.) **9**, 409–14 (1939); cf. *C. A.* **32**, 2940[2].—Reduction of 2-chloro-6-nitrobenzothiazole with AcOH and Fe gives the corresponding amine (I), m. 164°. If Zn and HCl are used, yellow crystals, m. above 300°, are formed. By the diazo reaction with I are prepd. 2,6-dichlorobenzothiazole, m. 101°, and 2-chloro-6-iodobenzothiazole, m. 137°. In all these compds. the Cl in the 2-position is easily replaced in reactions with amines. By this reaction the following *benzothiazoles* are prepd.: 2-phenylamino, m. 159°, 2-phenylamino-6-nitro, m. 247°, *2-(2'-methylphenyl)amino*, m. 204–5°, *2-(4'-dimethylaminophenyl)amino-6-nitro*, red-orange, m. 234°, *4-di-(6'-nitrobenzothiazole-2'-amino)phenylarsinic acid*, m. 63°, *2-(γ-piperylideno-β-hydroxypropyl)amino*, reddish yellow oil, *2-(δ-diethylamino-α-methylbutyl)amino*, yellow oil, *2-(δ-diethylamino-α-methylbutyl)amino-6-nitro*, thick orange oil, *& (δ-diethylamino-α-methylbutyl)amino-6-chloro*, thick yellow oil, *2-(δ-diethylamino-α-methylbutyl)-amino-6-iodo*, thick yellow oil. In spite of their resemblance to similar quinoline and acridine compds., none of these substances is an antimalarial. H. M. L.

Synthetic experiments in the benzofurone series. I. Synthesis of karanjin-α-carboxylic acid. S. Rangaswami and T. R. Seshadri. *Proc. Indian Acad. Sci.* **9A**, 259–64 (1939).—*Karanjin* isolated from the oil of *Pongamia glabra* is, according to Limaye (*Proc. Indian Sci. Congr.* **1925**, 118, **1926**, 151), *3-methoxyflavono-7,8-furan* (I).



It m. 158°. Demethylation yields *karanjonol*, m. 192–3°; *Ac deriv.*, m. 175–6°; *Bz deriv.*, m. 180°; *Et ether*, m. 125–6°. As a result of a publication by Manjunath, *et al.* (*C. A.* **33**, 2520[8]) R. and S. report on their preliminary expts. on the synthesis of I. To try out the method of Spaeth and Pailer (*C. A.* **29**, 5096[1]) with a simpler compd. the Na salt of 2-methyl-3-methoxy-7-hydroxychromone-8-aldehyde (II), m. 180°, is heated with $BrCH_2CO_2Et$ for 8 hrs. in an oil bath at 170–5°. After distg. off the excess of ester, the solid residue is recrystd. from EtOH. The yield of *carbethoxymethyl ether* of II is 80%; it m. 180° and mixed with II it m. 150 2°. When this method is applied to *3-methoxy-7-hydroxyflavone-8-aldehyde* (III) only poor yields are obtained. When, however, 0.5 g. III is refluxed with 4 cc. $BrCH_2CO_2Et$ in 40 cc. C_6H_6 in the presence of 2 g. K_2CO_3 for 16 hrs., the *carbethoxymethyl ether* (IV) of III is obtained in 70% yield and m. 116–17°. Hydrolysis of 1 g. IV by boiling with 50 cc. 5% KOH for 1 min. and acidification yields *3-methoxyflavono-7,8-furan-α-carboxylic acid* (V) which is purified via its Na salt. The *free acid* m. 224–6°. Like its *Na salt*, V is sparingly sol. in H_2O. The decarboxylation of V is difficult and further attempts are in progress. I. E. Brauns



Synthesis of coumarins and chromones. D. Chakravarti. *Proc. Natl. Inst. Sci. India* **5**, 235–42 (1939).—A review with 40 references. G. G.

Rottlerin. III. Thomas Backhouse and Alexander Robertson. *J. Chem. Soc.* **1939**, 1257–61; cf. *C. A.* **32**, 4555[3].—Previous work led to the conclusion that tetrahydrorottlerone (I) had the formula II (R = CH_2Ph) or III (R = CH_2Ph), of which the former was preferred. Syntheses of these compds. show that I is not identical with II or III. 5,7-Dimethoxy-6-formyl-8',2-dimethylchroman (*C. A.* **31**, 3038[8]) yields an *oxime*, m. 181°, which is dehydrated by Ac_2O at 100° in 1.5 hrs. to *6-cyano-5,7-dimethoxy-2,2-dimethylchroman* (IV), m. 126–7°; attempts to synthesize the di-Me ether of II by the action of $PhCH_2CH_2MgBr$ upon IV did give satisfactory results. 5,7-Dihydroxy-2,2-dimethylchroman (IV) and MeCN in Et_2O contg. $ZnCl_2$, satd. with HCl and allowed to stand for 6 days, followed by hydrolysis with H_2O, give a mixt. of *5,7-dihydroxy-6-acetyl-2,2-dimethylchroman* (II, R = H), straw-colored, m. 229°, and giving a purple-violet $FeCl_3$ reaction in EtOH (*2,4-dinitrophenylhydrazone*, dark red, m. 227.5°), and the *8-Ac deriv.* (III, R = H), pale yellow, m. 150°, and giving a purple-violet $FeCl_3$ reaction (*2,4-dinitrophenylhydrazone*, red, m. 228.5°); at first these 2 compds. were isolated by manual sepn. of the large crystals from MeOH; later, 2 g. of the mixt. was heated to boiling with C_6H_6, the ext. immediately decanted and the residue crystd. from C_6H_6 and then from dil. MeOH, giving II (R = H); crystn. of the residue from the C_6H_6 mother liquors from MeOH and then from dil. MeOH gives III (R = H). IV and AcCl with $AlCl_3$ in $PhNO_2$ give II (R = H). III (R = H) and MeI with K_2CO_3 in Me_2CO, refluxed 1 hr., give the *5-Me ether*, pale yellow, m. 78°, which gives a brownish purple color with $FeCl_3$; reaction of the ether with AcOEt and EtONa gives the 8-acetoacetyl deriv., which was not purified but cyclized by HCl in EtOH to *5'-methoxy-2,2',2'-trimethylchromano-8',7',-5,6-γ-pyrone*, m. 168°. III (R = H) and BzH with 50% aq. KOH in EtOH, kept at 50° for 15 min. and then at room temp. for 24 hrs., give *5,7-dihydroxy-8-cinnamoyl-2,2-dimethylchroman*, orange-red, m. 176–7°, which gives a dark brown $FeCl_3$ reaction; catalytic reduction with Pd-C gives *5,7-dihydroxy-8-β-phenylpropionyl-2,2-dimethylchroman* (III, R = CH_2Ph), pale yellow, m. 172°; $FeCl_3$ gives a purple-violet color. IV and $PhCH_2CH_2CN$, treated as above, give III (R = CH_2Ph) and the *6-β-phenylpropionyl isomer* (II, R = CH_2Ph), m. 171°, which gives a purple-violet $FeCl_3$ reaction; methylation gives an oil; the *oxime* of the di-Me ether m. 129.5°. III (R = CH_2Ph) and MeI with K_2CO_3 in Me_2CO give *7-hydroxy-5-methoxy-8-β-phenylpropionyl-2,2-dimethylchroman* (V), m. 104°, $FeCl_3$ gives a brownish violet color; this was not cyclized by Ac_2O-AcONa and did not condense with AcOEt. The corresponding

benzyl ether (VI), m. 112–13°, gives a brownish purple color with $FeCl_3$. V and MeI give the *5,7-di-MeO deriv.*, m. 94°. VI gives the *7-MeO deriv.*, m. 67.5°, debenzylation of which with Pd-C in AcOH gives *5-hydroxy-7-methoxy - 8 - β - phenylpropionyl - 2,2 - dimethylchroman*, 158°

C. J. West

Structure of the red oxidation products of tocopherols and related substances. Lee I. Smith, Willa B. Irwin and Herbert E. Ungnade. *Science* **90**, 334–5(1939); cf. *C. A.* **33**, 8613⁹.—When 2,2,5,7,8-pentamethyl-6-hydroxychroman is treated with HNO_3 or $AgNO_3$, a red cryst. compd. (I), m. 109–10°, is obtained. I is the *o*-quinone *2,2,7,8-tetramethyl-5,6-diketochroman*. It forms a phenazine (II), m. 151–2°, with *o*-$C_6H_4(NH_2)_2$. II shows a strong greenish yellow fluorescence in ultraviolet light. The red *o*-quinone from α-tocopherol is an *oil*, which reacts with *o*-$C_6H_4(NH_2)_2$ to give a *phenazine* (III) which is also an oil. Solns. of III show the same fluorescence as shown by II. Tocopherols are converted into analogs of I by treatment with HNO_3 or $AgNO_3$. The formation of red *o*-quinones is not confined to 6-hydroxychromans, but also occurs with 5-hydroxycoumarins and related compds. The mechanism of the reaction is obscure. An alc., primary or secondary, must be used as the solvent and the results indicate that the alc. is probably a reagent as well as a solvent. Felix Saunders

Syntheses of chroman derivatives with the ring system of α-tocopherol. II. Walter John and Philipp Günther. *Ber.* **72B**, 1649–53(1939); cf. *C. A.* **33**, 1731⁸.—In a continuation of efforts to obtain lower homologs of α-tocopherol with any desired side chain in the 2-position a new method of prepg. chroman derivs. was followed. *2,4,5-Trimethyl-3,6-dimethoxybenzylideneacetone* (I) (80% from 10 g. $Me_3(MeO)_2C_6CHO$ (II) (Smith, *C. A.* **28**, 1680⁸) in 90 cc. of 70% acetone treated in the course of 0.5 hr. with 0.4 g. NaOH in 10 cc. water, kept at 15° during the 1st hr. and then 2 hrs. at 20°), faintly yellow, m. 61–2°; as by-product was obtained *hexamethyltetramethoxydibenzylideneacetone*, greenish yellow, m. 188°. I is hydrogenated with Pd sponge in alc. to the *benzyl ketone* (III), m. 76°, converted with MeMgI into the carbinol $Me_3(MeO)_2C_6CH_2CH_2C(OH)Me_2$. Without isolating the carbinol, the product was boiled with HBr (d. 1.49) in AcOH, giving 2,2,5,7,8-pentamethyl-6-hydroxychroman, m. 93–4° (1.4 g. from 2.4 g. III). Unfortunately the method did not prove well adapted to the introduction of longer side chains into the 2-position of the chroman system. Thus, III with $C_{12}H_{25}MgBr$ gave the carbinol, to be sure, but attempts to cleave the ether union were extraordinarily unsatisfactory. It was first attempted to cleave the MeO groups in III before subjecting it to the Grignard reaction, but boiling with HBr in AcOH resulted in simultaneous reduction to *2,5,7,8-tetramethyl-6-hydroxychroman*, m. 145°. *2,4,5-Trimethyl-3,6-hydroquinone di-Et ether* (11.1 g. from 9.9 g. hydroquinone and Et_2SO_4 in boiling abs. EtOH), m. 34°, gives by the Smith method only a moderate yield of *2,4,5-trimethyl-3,6-diethoxybenzaldehyde*, m. 100.5°, becomes, like II, yellow in the air and colorless again in the dark; in the residue from the steam distn. there remain 2 substances sepd. by fractional crystn. from petr. ether.: *2,4,5-trimethyl-3,6-hydroquinone-1-aldehyde*, yellow, m. 149°, and a *mono-Et ether*, m. 99°, of the latter. The synthesis of lower homologs of α-tocopherol was finally effected by 2 methods; one is described in part III below; the other, based on the above acetone condensation process, starting from pseudocumylaldehyde with subsequent introduction of the HO groups, will be reported later. III. **The introduction of a side chain into tetramethylhydroxychroman.** Walter John and Margarete Schmeil. *Ibid.* 1653–6.—2,5,7,8-Tetramethyl-6-hydroxychroman is converted either with $FeCl_3$ (*C. A.* **33**, 2896²) or, better, by boiling with AgOAc in MeOH into 1-γ-hydroxybutyl-3,4,6-trimethylbenzoquinone (I) which is reduced with alk. $Na_2S_2O_4$ to the *hydroquinone*, m. 138°, and is oxidized by CrO_3 in AcOH below 30° to the *1-γ-ketobutylquinone* (II) (2.0 g. from 2.4 g. I), yellow, m. 56°. With Zn dust and a few drops of water in AcOH II gives crystals, $C_{12}H_{18}O_3$, m. 122°, absorption max. at 289 mμ, ε 3520; as the pure product from MeOH is more difficultly oxidized than free hydroquinones by $AgNO_3$ it is probably the (isomeric) *hemiacetal* rather than the *hydroquinone* (III) itself. Reductive acetylation of II gives the *diacetate*, $C_{17}H_{22}O_5$ (IV), m. 94°. I on reductive benzoylation with BzCl in alk. soln. gives a *dibenzoate*, $C_{27}H_{28}O_5$, m. 93°, which with CrO_3 in AcOH at 30° yields almost quantitatively the *dibenzoate*, $C_{27}H_{26}O_5$ (V), of II, m. 143°. III (1.1 g.) in ether, slowly added to MeMgI in boiling ether, boiled 3 hrs. longer, evapd., decompd. with cooled HCl and ice, dissolved in alc. and refluxed with a little Zn dust in a weak current of HCl gives 0.4–0.5 g. 2,2,5,7,8-pentamethyl-6-hydroxychroman, m. 93°. In the same way is obtained the 2-dodecyl analog, isolated as the allophanate (0.3–0.4 g. from 1.1 g. III), m. 180°. IV and V form with Grignard reagents only difficultly sol. addn. products which were not further investigated.

C. A. R.

γ-Substituted derivatives of resorcinol III. Synthesis of 5,6-dimethoxyflavone. Koiti Nakazawa. *J. Pharm. Soc. Japan* **59**, 495–9(1939); cf. *C. A.* **33**, 8186⁹.—2,6-Dihydroxyacetophenone (15 g.) in 120 cc. acetone, 10 g. anhyd. K_2CO_3 and 14 g. MeI when boiled for 6 hrs. under a reflux gave 9.2 g. 2-methoxy-6-hydroxyacetophenone (I), $C_9H_{10}O_3$, m. 58.5°. Oxidation of I in alk. soln. gave 2-methoxy-3,6-dihydroxyacetophenone $C_9H_{10}O_4$, m. 91°, sol. in most org. solvents; di-Bz deriv. (II), m. 102°. II (5 g.) in 100 cc. anhyd. toluene and 10 g. $NaNH_2$ when shaken gave 2.5 g. 2-methoxy-3-benzoxy-6-hydroxydibenzoylmethane (III), $C_{23}H_{18}O_6$, m. 152.5°, sol. in acetone and AcOEt, and MeOH and alc. while warm. III (2 g.) when treated with H_2SO_4 gave 1.2 g. 5-methoxy-6-hydroxyflavone (IV), $C_{16}H_{12}O_4$, m. 185°; 5-methoxy-6-benzoxyflavone, $C_{23}H_{16}O_5$, m. 206°. Methylation of IV gave 5,6-dimethoxyflavone, $C_{17}H_{14}O_4$, m. 199°, sol. in many org. solvents. F. I. Nakamura

Flavonol glucoside of Calystegia japonica Chois. Genitì Hukuti. *J. Pharm Soc. Japan* **59**, 258–60 (English abstr. 85–6)(1939).—The MeOH ext. of the leaves and stems of *Calystegia japonica* Chois gave a flavonol glucoside, $C_{27}H_{30}O_{16}.2H_2O$, m. 223–4°, which on hydrolysis gave an aglucon, $C_{15}H_{10}O_6$, m. 272–4°; acetate m. 181–2°. Glucose and rhamnose were also identified in the hydrolyzate. 2-Hydroxy-4,4',6-trimethylchalcone (1 g.) in MeOH and 15% H_2O_2 and 16% NaOH when treated in the cold gave 3-hydroxy-4',5,7-trimethoxyflavone (I), $C_{15}H_6O_2(OH)(OMe)_3$, m. 150–1°. Methylation of the above glucoside followed by hydrolysis gave a compd., m. 149–50°, which did not depress the m. p. of I.

F. I. Nakamura

Pigments of cotton flowers. VII. Position of the glucose residue in gossypitrin. P. Suryaprakasa Rao and T. R. Seshadri. *Proc. Indian Acad. Sci.* **9A**, 177–80 (1939); cf. *C. A.* **33**, 5396⁵.—The position of the sugar group in gossypitrin (I) is still uncertain. Various attempts at a complete methylation of I have failed. Use of the method of Baker and Robinson (*C. A.* **23**, 2180) of deacetylation and methylation in acetone soln. leads to a product in which all the phenolic OH groups and 1 OH group in the sugar residue are methylated. The methylated I so obtained m. 290° (decompn.). Hydrolysis of this product by refluxing with 7% H_2SO_4 yields a *pentaethylgossypetin*, m. 252–4°, which is identical with 3,5,8,3',4'-pentamethylgossypetin (II) obtained by Baker. Acetylation of II with Ac_2O and AcONa gives *7-Ac deriv.*, it crystallizes with $3H_2O$ and sinters from 100–5° (dehydration) and m. 167–9°. Methylation of II with Me_2SO_4 and NaOH yields *hexamethylgossypetin*, m. 170–2°.

I is therefore a 7-glucoside of gossypetin. **VIII. Constitution of herbacitrin and quercimeritrin.** *Ibid.* 365–9.—Herbacitrin (I), a flavonol glucoside, recently isolated by Neelakantam and Seshadri (*C. A.* **29**, 6625[5]), was tentatively represented as the 7-glucoside of herbacetin (*C. A.* **31**, 4978[9], 6246[3]). To establish its constitution definitely, and since I could not be completely methylated by CH_2N_2 (*C. A.* **33**, 5396[5]), which leaves the 5-OH group unaffected, I is first acetylated and the *acetylated* I, m. 222–4°, methylated in Me_2CO by simultaneous deacetylation and methylation with Me_2SO_4 and 20% NaOH. The completely methylated I was not isolated but is immediately hydrolyzed by refluxing it with 2% H_2SO_4 for 2 hrs. in 70% EtOH. When the EtOH is distd. off, a yellow cryst. product seps. which is identified by its m. p., 269–70°, as *3,5,8,4'-tetramethylherbacetin*. Further methylation gives *pentamethylherbacetin*, m. 156–8°. *Quercimeritrin acetate*, when methylated and hydrolyzed in the same way, yields *3,5,3',4'-tetramethylquercetin*, m. 284–5° which when further methylated yields pentamethylquercetin, m. 151–3°. These results confirm that I is the 7-glucoside of herbacetin and quercimeritrin the 7-glucoside of quercetin. F. E. Brauns

Use of high temperatures in organic preparations. A. J. van Pelt, Jr. *Chem. Weekblad* **36**, 613–14(1939).—The use of high temps. for the prepn. of pyridine derivs and unsatd. hydrocarbons is discussed. F. Saunders

Synthesis of nitrogen-ring compounds. XVIII. Ser. 4. Synthesis of condensed nitrogen-ring compounds. Pt. 3. Synthesis of octahydropyridocoline. Sigehiko Sugasawa and Nanjun Lee. *J. Pharm. Soc. Japan* **59**, 326–8(in English, 113–15)(1939); cf. *C. A.* **33**, 6318[5], 8617[9]. Catalytic reduction of 3 g. Et γ-2-pyridylbutyrate, according to Clemo (*C. A.* **27**, 985), gave 1.7 g. Et γ-2-piperidylbutyrate, b_4 114°, which gave on heating at 200° for 10 min. 1.25 g. 4-ketooctahydropyridocoline (I), b_4 118°. I (1.1 g.) in 300 cc. dry xylene when heated on an oil bath at 80° for 30 min. with 0.85 g. P_2O_5 and 1.25 g. K_2S gave 0.75 g. thiolactam (II), b_3 162°, m. 80°. Electrolytic reduction of 0.7 g. II gave octahydropyridocoline in the form of a picrate, $C_{15}H_{20}O_7N_4$, m. 193°, which did not depress the m. p. of norlupinane picrate of natural origin. F. I. Nakamura

Some derivatives of triacetonamine. Mario Passerini and Giuseppe Losco. *Ann. chim. farm.* (Suppl. to *Farmital.*) Aug., **1939**, 64–7.—In $CHCl_3$ soln. at room temp. 1 mol triacetonamine, 1 mol. *p*-phenetyl isocyanide and 2 mols. BzOH react slowly to form the BzOH salt of 2,2,6,6-tetramethyl-4-benzoxypiperidine-4-carboxy-*p*-phenetylamide, $CH_2.CMe_2.NH.CMe_2.CH_2C(OBz)CO{-}HC_6H_4OEt.BzOH$. An excellent yield of colorless crystals, m. 250°, is obtained after standing several days. This salt is slightly sol. in water, EtOH and C_6H_6. Na_2CO_3 liberates the base, insol. in water. The anhyd. base does not readily crystallize, but a monohydrate, m. 134–8°, readily crystallizes from C_6H_6 contg. a little water. The HCl salt is slightly sol. and the acetate and tartrate are readily sol. in water.

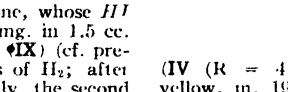
with alc. KOH yields the 2,2,6,6-tetramethyl-4-hydroxypiperidine-4-carboxy-*p*-phenetylamide, nearly insol. in water, colorless crystals from C_6H_6, m. 116–18°. L. E. Gilson

Proof of the steric nature of the ortho effect in the hydrogen-exchange reactions of aromatic tertiary amines. Weldon G. Brown, Alex H. Widiger and Nicholas J. Hetang. *J. Am. Chem. Soc.* **61**, 2597–601(1939).—The decrease of H liability caused by an *o*-F atom is much less than that caused by an *o*-Cl atom. This supports the theory that the ortho effect is primarily a steric effect having to do with the tendency of an ortho substituent to block the formation of quinonoid structures. A more decisive test of the theory is provided by a study of the exchange reactions of cyclic bases *N*-Methylindoline and *N*-methyltetrahydroquinoline, having bicyclic structures which are coplanar, exchange H readily, while *N*-methylhomotetrahydroquinoline, being heterocyclic and probably highly puckered, exchanges H at a relatively slow rate. A. B. Garrett

Synthesis of naphthyridine derivatives. III. Constitution of dihydroxyquinopyrine. Supplement. Alkalolysis of quinolin imide. Eiji Ochiai and Iwao Arai. *J. Pharm. Soc. Japan* **59**, 458–61(in German, 152–5)(1939); cf. *C. A.* **33**, 2525[6].—Et quinolinylglycinate (0.5 g.) and 0.15 g. Na in MeOH when heated in a sealed tube at 100° for 45 min. gave a compd. (I), $C_{10}H_8O_4N_2$, decompg. 219–20°, which did not lower the m. p. of Me 1,4-dihydroxy-2,5-naphthyridine-3-carboxylate; picrate decompg. 220°; monoacetate, $C_{12}H_{10}O_5N_2$, m. 224°. Quinolinimide (1 g.) in 30 cc. abs. alc. and 0.26 g. K in abs. alc. when treated on the water bath for 30 min. with 1.5 g. $BrCH_2CO_2Et$ gave a small amt. of a compd. (II), $C_7H_6O_2N_2(IEt)_2$, m. 98° (quinolinic monoamide mono-Et ester) and 0.7 g. Et quinolinylglycinate, m. 122°. Decompn. of II with HBrO gave aminopyridinecarboxylic acid, $C_6H_6O_2N_2$, decompg. 295–6°. Decompn. of quinolinimide with HBrO gave β-aminopicolinic acid, $C_6H_6O_2N_2$, decompg. 211°. F. I. Nakamura

Ergot alkaloids. XVIII. Production of a base from lysergic acid and its comparison with synthetic 6,8-dimethylergoline. Walter A. Jacobs and R. Gordon Gould, Jr. *J. Biol. Chem.* **130**, 399–405(1939); cf. *C. A.* **32**, 9091[3]; **33**, 1332[3], 6386[9].—The unsatd. lactam, obtained on pyrolysis of dihydrolysergic acid, was catalytically hydrogenated to the satd. lactam which was then reduced by Na in BuOH to give the *base*, $C_{16}H_{20}N_2$ (I), micro m. p. 205–12°; *HCl salt*, $[\alpha]_D^{25}$ −30°. 3-Amino-1-naphthoic acid sulfate, the α,γ-di-Et ether of β-methylglycerol and PhNO were heated in H_2SO_4, giving *3-methyl-5,6-benzoquinoline-7-carboxylic acid* (II), m. 320–4° (decompn.); *Et ester*, m. 85–6°. Nitration of II gave principally the *3'-nitro deriv.*, m. 320–4° (decompn.), which on reduction with $Fe(OH)_2$ followed by lactamization gave the yellow *3-methyl-3'-amino-5,6-benzoquinoline-7-carboxylic lactam* (III), m. 288–9°. III and MeI gave the *1-methiodide*, m. 294–6° (decompn.); *1-methochloride* (IV), m. 290–5° (decompn.). Catalytic reduction of IV gave *1,2,3,4-tetrahydro-1,3-dimethyl-3'-amino-5,6-benzoquinoline-7-carboxylic lactam* (V), m. 249–50° (decompn.). V was reduced with Na in BuOH, giving *6,8-dimethylergoline*, $C_{16}H_{20}N_2$ (VI), m. 222–3°, mixed m. p. with I, 205–20° (the difference in m. p. of I and VI may be attributed to stereochem. factors. 5,6-Benzoquinaldine-7-carboxylic acid was nitrated to give the *3'-nitro deriv.*, which on reduction gave the *3'-amino acid lactam*, m. 319–20° (decompn.). D. S. Searle

Isolobinine, a new alkaloid from Lobelia inflata. Otto Thoma. *Ann.* **540**, 99–103(1939). The fraction T64 of Richter (*C. A.* **33**, 7377[5]) is now termed *isolobinine* (I); it has the formula $C_{15}H_{25}O_2N$, and, cryst. from Et_2O-petr. ether, m. 78°; *HCl salt*, with 1 mole H_2O, m. 132°, anhyd., m. 154°, $[\alpha]_D^{25}$ −76° (2% aq. soln.); phosphate, m. 80°, decomp. in moist air; the *oxime* is amorph., whose *HCl salt* m. 183°. Catalytic reduction gives a *dihydro deriv.* (II), b_4 175°. Thermal decompn. of I at 10 mm. (170–215°) gives an oil (2-butanone?), whose *p*-nitrophenylhydrazone m. 180°. Oxidation of I with CrO_3 gives BzOH (73.4% of 1 mole) and AcOH; II gives 35% of the theory of scopolic acid and 1.68 moles of BzOH. C. J. West



Lobelia alkaloids. VII. Accessory alkaloids of Lobelia inflata. Heinrich Wieland, Walter Koschara, Elisabeth Hane, Jany Renz, Werner Schwarze and Werner Linde. *Ann.* **540**, 103–56(1939); cf. *C. A.* **26**, 989.—The first portion of this paper deals with the methods of fractionation of the alkaloids. *dl*-Lelobanidine (I), $C_{15}H_{29}O_2N$, m. 68°; *HCl salt*, m. 78–9°; *HI salt*, m. 159°; *chloroplatinate*, yellow 6-sided prisms; *methiodide*, m. 162–4°; di-Bz deriv., m. 178° (thus the 2 HO groups are present as HO groups). I (3.6 g.) in 50 cc. AcOH, treated dropwise with 1.7 g. CrO_3 in AcOH during 0.5 hr., gives 1 g. of the *perchlorate*, m. 136°, of *dl-lelobanine* (II), $C_{15}H_{23}O_2N$, an oil; *HCl salt*, m. 142°. Oxidation of II with CrO_3 in H_2SO_4 gives BzOH, AcOH, $EtCO_2H$, scopolic acid and methylgranatic acid (III). Boiling II with excess

of MeI for 20 min. and shaking with Ag_2O (odor of Me_2NH) give a deep-yellow neutral oil, which is catalytically reduced to a glycol, $C_{17}H_{36}O_2$, $b_{0.03}$ 117–18°, m. about 8°; CrO_3 in dil. H_2SO_4 gives *l-benzoyl-7-propionylheptane* (IV), m. 51°. $(CH_2)_7(CO_2Et)_2$ on partial hydrolysis and

C_6H_6 gives IV; *semicarbazone*, m. 186° (decompn.). Therefore I is PhCH(OH)$[CH_2]_4$CH$_2$.CH$_2$.CH(CH$_3$CH-OHEt).NMe. *l*-Lelobanidine I (V) forms a *HCl salt* with 2 moles H_2O, m. 86°, $[\alpha]_D$ −41.5° (0.0351 g. in 1.5 cc. EtOH); *HI salt*, m. 171°; *perchlorate*, m. 176°; *di-Ac deriv. HCl salt*, m. 195–6°; *benzenesulfonyl deriv. HCl salt*, m. 110–15°. V with CrO_3 in AcOH (5 days at room temp.) gives *l-lelobanine* (VI), whose *HCl salt* m. 186°, $[\alpha]_D$ 19.5° (13.6 mg. in 1.5 cc. EtOH). V with CrO_3 in AcOH gives BzOH, $AcOH$, $EtCO_2H$ and *l*-III. I may be resolved through the *d*-camphorsulfonate; the salt is crystd. from EtOH-Et_2O, followed by crystn. of the HCl salt from EtOH-Et_2O. *l*-Lelobanidine gives a *HCl salt* with 1.5 moles of H_2O, m. 102.5°, $[\alpha]_D$ −41.7° (19.8 mg. in 1.5 cc. EtOH); *HI salt*, m. 165°, $[\alpha]_D$ 33° (25 mg. in 1.5 cc. EtOH); oxidation gives VI. *d-Norlelobanidine* (VII), $C_{14}H_{27}O_2N$, m. 90°, $[\alpha]_D$ 62.8° (0.0518 g. in 5 cc. EtOH); *HCl salt*, m. 193°; *HBr salt*, m. 202°; *HI salt*, needles or tetrahedra, m. 190°; *di-m-nitrobenzoyl deriv.*, m. 212°; *monobenzene-disulfonyl deriv.*, m. 150°; Hofmann degradation of the methiodide of *d*-norlelobanine gives III. Methylation of VII with *p*-$MeC_6H_4SO_3Me$ gives V. *d*-Norlelobanine, m. 174°, $[\alpha]_D$ −41.5° (19.6 mg. in 1.5 cc. EtOH). Lobinine VIII (part VI) with CrO_3 in 15% H_2SO_4 gives 1 mole of BzOH and a *base*, $C_8H_{14}NO_4$, m. 207.8°, which is unsatd. toward $KMnO_4$ and absorbs 1 mole of H_2 but a uniform reduction product could not be isolated. VIII with PtO_2 and H_2 gives 25–30% of α-lelobanidine, whose *HI salt* m. 181°, $[\alpha]_D$ −38.2° ± 0.5° (17.2 mg. in 1.5 cc. EtOH); *perchlorate*, m. 152°. Isolobinine (IX) (cf. preceding abstr.) absorbs more than 2 moles of H_2; after absorption of 2 moles (the first very quickly, the second 5–3 times as long), the compd. m. 83°; the perchlorate, m. 176°, and the HCl salt, m. 86°, are identical with those of VI. [illegible] *HCl salt*, m. 161°, which is not identical with lobinol or with XII. Oxidation of IX with CrO_3 in AcOH gives 50% of isolobinanine, whose *HCl salt* m. 151°, $[\alpha]_D$ 11 ± 0.3° (23.8 mg. in 1.5 cc. EtOH); the methiodide quickly liquefies in the air; $NaHCO_3$ gives the unsatd. diketone (X), m. 82–3°, which is also obtained from VI. Lobinanidine, $C_{18}H_{27}O_2N$, m. 95° $[\alpha]_D$ −17.9° (0.0248 g. in 1.5 cc. EtOH); *HCl salt*, m. 169°; *HI salt*, m. 200°; *benzenesulfonyl deriv.*, m. 125°, clears 135°. Oxidation with CrO_3 in AcOH at 70–80° gives lobinaninic, whose perchlorate m. 130°. Hofmann degradation of the methiodide gives X. Oxidation of lobinanidine gives lobinic acid; catalytic reduction gives 60% of α-lelobanidine, whose *HI salt* (XI) m. 174°, $[\alpha]_D$ −37° (50 mg. in 1.5 cc. EtOH); crystal examn. showed that this was not identical with β-lelobanidine, m. 181°. Isolobinanidine (XII) gives a *HCl salt*, with 2 moles H_2O, m. 111°, $[\alpha]_D^{30}$ −28.3° (0.041 g. in 2 cc. H_2O); *HI salt*, m. 164°; catalytic reduction gives V. The following diketones were prepd. for comparative purposes. $AcCHNaCO_2Et$ and 48 g. $(CH_2)_5Br_2$ give 26 g. of 6-carbethoxy-6-acetylhexyl bromide, b_1 180–200°; 40% HBr gives 6-acetylhexyl bromide, b_{30} 202–3°; with $BzCHNaCO_2Et$ there results *7-acetyl-1-benzoyl-1-carbethoxyheptane*, which with KOH in MeOH gives *1-benzoyl-7-acetylheptane*, m. 64.5°; semicarbazone, m. 194°. $EtCO_2(CH_2)_6COCl$, b_{12} 146°, gives $MeCH_2CO(CH_2)_6CO_2Et$, light yellow oil, b_{10} 140°. $MeCH_2CO(CH_2)_6COCl$ and finally *1-propionyl-6-benzoylhexane*, m. 44–5°. *Alkaloid* $C_{19}H_{28}N_2O_3$, m. 232° (decompn.); *HCl salt*, m. 299–300° (decompn.); *HI salt*, m. 279°; *perchlorate*, m. 254–5°; *methiodide*, m. 244° (decompn.), which gives no amine odor with Ag_2O; *Bz deriv.*, light yellow, m. 280° (decompn.); *Br deriv.*, m. 288° (decompn.). *Alkaloid* $C_8H_{19}ON$, m. 85–7°; *alkaloid* $C_{14}H_{21}ON$, m. 103°; these were sepd. by distn., b_{1-2} 118–20° and 135–7°, resp. *Alkaloid* $C_{14}H_{21}ON$, m. 81°; *chloroaurate*, m. 182°; *Bz deriv.*, m. 118°; oxidation gives the *ketone*, $C_{14}H_{19}ON$, whose HCl salt, with 1 mole H_2O, m. 109°; oxidative degradation gives a compd. $C_7H_{13}O_2N$, m. 235°. Another product isolated in this work was β-phenyl-β-hydroxypropionic acid, m. 116°, $[\alpha]_D$ −18.4 ± 0.5°.

C. J. West

Synthesis of 5-substituted rubans. G. R. Clemo and E. Hoggarth. *J. Chem. Soc.* **1939**, 1241–4.—Lepidine (40 g.), 44 g. chloral and 100 cc. C_6H_6N, warmed at 85–90° for 2 hrs., give 80% of γ-trichloro-β-hydroxy-α-(4-quinolyl)propane, m. 178°; adding 65 g. during 2 hrs. to 65 g. KOH in 300 cc. abs. EtOH on the water bath gives 80% of β-4-quinolylacrylic acid, m. 270°; oxidation of 30 g. acid in a soln. of 11 g. Na_2CO_3 in 500 cc. H_2O with 60 g. $KMnO_4$ in 1.5 l. H_2O at −10° gives 58% (overall yield 38–40%) of quinoline-4-aldehyde (I), b_4 122–3°, m. 52°; *picrate*, yellow, m. 179° (contains 1 mole of EtOH). 3-Ketoquinuclidine (II) (C. and Metcalfe, *C. A.* **32**, 1701[3], term it the 2-deriv.) and BzH in abs. EtOH contg. piperidine or KOH, refluxed 8–10 hrs., give *2-benzylidene-3-ketoquinuclidine*, light yellow, m. 133°; *phenylhydrazone*, light yellow, m. 184°. II (0.5 g.) and 0.8 g. I in AcOH, satd. with dry HCl at 0°, and after 2–3 hrs. warmed at 80–5° for 8 hrs., give 0.2 g. *5-keto-6,9-rubanene* (III), deep yellow, m. 153°; III results in 0.4–0.5 g. yield from 0.5 g. II and 0.65 g. I with piperidine acetate in abs. EtOH; after keeping 60 hrs. in the cold and then heating momentarily to boiling; *picrate*, red, m. 209°; *chloroplatinate*, orange needles, decomp. above 260° without melting. Catalytic reduction of 0.5 g. of III with Pd-C in MeOH gives 0.3 g. of *5-ketoruban*

(IV (R = 4-quinolyl)), m. 125–6°; *phenylhydrazone*, yellow, m. 198°; *picrate*, deep yellow, m. 168°. Reduction of 0.5 g. of IV with $(iso\text{-}PrO)_3Al$ in iso-PrOH gives 0.3 g. of *ruban-5-ol*, m. 198°; *picrate*, yellow, m. 188–9°. IV (0.3 g.) with EtMgI in Et_2O at −10° gives 0.03–0.05 g. of *5-ethylruban-5-ol* (V), m. 139°; *picrate*, yellow, m. 161°. III (0.8 g.) and EtMgI in Et_2O at 0° give 0.05 g. of a *compd.* $C_{19}H_{22}ON_2$, m. 164°; *picrate*, deep yellow, m. 150°; cryst. compds. could not be prepd. with $N_2H_4.H_2O$, $PhNHNH_2$, NH_2OH or $H_2NNHCONH_2$; no Me_2CO was detected in an attempted reduction with $(iso\text{-}PrO)_3Al$ and the compd. was unchanged on boiling with HCO_2H or Ac_2O; catalytic reduction did not yield V. C. J. West

Modified cinchona alkaloids. VII. Constitution of niquidine. L. M. Gibbs and T. A. Henry. *J. Chem. Soc.* **1939**, 1294–9; cf. *C. A.* **33**, 3385[8].—In part VI the formula MeCH:C$^{\prime\prime}$HCH$_2$.CH[CH(OH)Q].NH.CH$_2$.CH$_2$ (in which Q is 6-methoxyquinolyl substituted in position 4) was suggested for the 2 geometrical isomers, niquidine (I) and isoniquidine (II), formed in the chalogenation of halodihydroquinidines by $AgNO_3$. Further evidence for this formula is now provided by a study of the oxidation products of "niquidine" (III) (the mixt. of I and II) and dihydroniquidine (IV). Oxidation of III with acid $KMnO_4$ at 0° gives A, quinanic acid (V) and very small yields of 2 *acids*, sepd. with difficulty, $C_{17}H_{11}O_4N_3$ (VI), yellow, m. above 300° (*Me ester*, m. 168°), and $C_{17}H_{20}O_4N_2$ (VII), m. 247° (decompn.); VI is considered to be HO_2CC:CH.C[CH(OH)Q]:NCH:CH, and VII the same structure but with the pyridyl group reduced to piperidyl. Oxidation of IV with H_2O_2 (heating 2 hrs. on water bath) gives a viscous oil which, crystd. from EtOH and extd. with dil. HCl, yields V and the *amine oxide* of V, $C_{11}H_9O_4N$, m. 272° (decompn.); *Et ester*, yellow, m. 141°; this was synthesized from V and H_2O_2 in NaOH by heating 4 hrs.

on the water bath; hydrogenation with Pd-$BaSO_4$ gives III. The H_2O_2 mother liquors contain β-propylglutaric acid (*diamide*, m. 195°; *dianilide*, m. 219°). Dihydroquinidine with H_2O_2 gives V and ω-ethylmethanetriacetic acid (VIII), m. 120°, $[\alpha]_D$ −1.3° (H_2O, *c* 1.006); *trianilide*, m. 280° (decompn.); *dianilide*, m. 222°. VIII was obtained in 25% yield by reacting Et α-cyanobutyrate and Et glutaconate with EtONa and hydrolyzing the crude CN ester (50% yield) with concd. HCl. C. J. West

Alkaloids of the lupines. XVIII.[5] Synthesis of allolupinine. K. Winterfeld and F. W. Holschneider. *Arch. Pharm.* **277**, 221-37(1939); cf. *C. A.* **33**, 3799[4].—This structural isomer of lupinine has now been prepd. and characterized. Starting with δ-chloro-γ-valerolactone, b_{14} 127.9°, the EtO deriv. was obtained by the action of abs. anhyd. NaOEt, the latter thereupon condensed with Et picolinate in C_6H_6 suspension, to *α-pyridyl α'-[δ-ethoxy-γ-valerolactonyl] ketone* (I) by the action of metallic Na. The resulting dark-brown, viscous oil, with an odor very like that of furfural, $b_{0.4}$ 173-5°, as a yellow, faintly odorous viscous oil having the compn. $C_{15}H_{19}O_3N$ (*Reinecke salt* brick-red powder, m. 128-30°; *$HgCl_2$ salt*; m. 100-2° (turbid), 116° (clear); *p-sulfonic acid phenylhydrazone*, faintly rose, m. 234-6°). Saponf., I yields *α-pyridyl α'-[δ-ethoxy-γ-hydroxybutyl] ketone* (II), $C_{12}H_{17}O_3N$, $b_{0.5}$ 110-20°, almost colorless oil becoming quickly dark in the air (*Reinecke salt*, m. 117° (decompg. 175-8°); *2,4-dinitrophenylhydrazone* bright yellow, m. 161-5°)). Hydrogenated, II gives *α-[α'-piperidyl]-α,δ-dihydroxy-ε-ethoxypentane*, (III) bright-yellow viscous oil yielding the *salt* $C_{12}H_{25}O_3N.HCl.HgCl_2$, m. 129°; *Bz deriv.*, $C_{19}H_{29}O_4N$, yellow oil; *Reinecke salt*, m. 129-30°. Cyclization of III to *4-ethoxymethyloctahydropyridocoline* (IV) was effected by progressive treatment with PBr_3, NaOEt, hydrogenation via Busch/Stove, benzoylation and distn., faintly yellow thin oil, b_{11} 142-4° (*aurate*, m. 85-7°; *$HgCl_2$ salt*, m. 125-6°; *Reinecke salt*, m. 143-5°), which reduced with HI (d. 1.7) gave *allolupinine*, viscous, yellow-brown oil with hay-like odor (after standing 2 weeks needle-like crystals were deposited) (*$HgCl_2$ salt*, m. 201° (decompn.); *Reinecke salt*, m. 152-3°; *aurate*, golden-yellow oil without melination to crystallize; *picrate*, similar behavior).

Kurchi alkaloids. II. Preparation of conessine and its secondary alkaloids. Alfred Bertho. *Arch. Pharm.* **277**, 237-57(1939); cf. *C. A.* **27**, 3715.—The prepn. of these bases, some 14 in no., already reported elsewhere is now described anew and at greater length. 17 references.

W. O. E.

Picrotoxin. IV. Ronald W. H. O'Donnell, Alexander Robertson and James C. Harland. *J. Chem. Soc.* **1939**, 1264-6; cf. *C. A.* **33**, 6861[3].—Reduction of picrotoxanin (I) with Pd-C in AcOEt ceased in 30-50 min. with the absorption of less than 50% of the theory of H. The crude non-acidic product (0.8 g. from 5 g. I) on boiling with *N* H_2SO_4 for 23 hrs. gives the β-dihydro deriv. (II) of I (*acetate*, m. 177°), picrotonol (III) and dihydropicrotoxic acid (IV). Since the α-isomer (V) of II is quant. converted into IV with H_2SO_4, the crude product contained both I and V. Reduction of 6 g. I in 250 cc. EtOH is complete in 3-6 hrs., approx. 2 mols H being absorbed. The crude product on boiling with H_2SO_4 gives II, III and IV; if the EtOH soln. is evapd. to about 50 cc. 1.2-1.9 g. of II crystallizes out and the 3 g. obtained on adding H_2O to the filtrate is largely II also. The reduction product can be sepd. into a neutral and acidic fraction with $NaHCO_3$. On boiling with H_2SO_4 the neutral fraction yields II, III and IV. By repeated crystn. from EtOH some V is also isolated. The acidic fraction, boiled with H_2SO_4 and crystd. from H_2O, gives an *acid*, $C_{15}H_{22}O_6.H_2O$, m. 183° (decompn.); *di-Me ester*, m. 164°; this may be a di-HO deriv. of $Me_2CHCH.CH_2.CH_2.CHMe.CH[(CH_2)_3$-$CO_2H].CHCO_2H$; it does not react with 2,4-$(O_2N)_2C_6H_3$-$NHNH_2$. Reduction of I in AcOH contg. HCl ceases in 4-6 hrs. after absorption of 0.4-0.5 mole H; evapn. of the filtered soln. and crystn. from H_2O give a *compd.* m. 232°, which is a eutectic mixt. of V and the precursor (VII) of III; 5% H_2SO_4 gives III and IV. Acetylation of the crude reaction product gives a small yield of the *acetate* of V, m. 190°; boiling with *N* H_2SO_4 gives a quant. yield of III. The mechanism of the formation of VI is discussed. α- and β-Bromopicrotoxinin (VII-VIII) and the corresponding α- and β-bromopicrotoxinic acids (IX, X) cannot be hydrogenated; the absence of an ethylenic linkage is confirmed by the lack of reaction with a mixt. of O_3 and O_2. α-Picrotoxinic acid (XI) is completely hydrogenated in AcOH with a PtO_2 catalyst in 2 min.; the dihydro deriv., $C_{15}H_{20}O_7$, m. 231°. The action of O_3 on XI gives HCHO and a ketone, which on boiling with III and red P yields norpicrotic acid and its HO deriv. and the ketone $C_{13}H_{16}O_2$. The β-isomer of XI cannot be hydrogenated nor is it oxidized by O_3. A mechanism for the formation of the satd. VII-VIII and IX-X is suggested. Treatment of I with Br in $CHCl_3$ gives a highly unstable product, which easily decomp. with evolution of HBr and on warming with H_2O gives a quant. yield of VII-VIII and HBr.

C. J. West

Sulfhydryl groups in proteins. III. The effect on egg albumin of various salts of guanidine. Jesse P. Greenstein, *J. Biol. Chem.* **130**, 519-26(1939); cf. *C. A.* **33**, 4610[9]. The denaturation of certain proteins is characterized in part by the appearance of titratable SH groups and for all of the proteins so far investigated, the greatest proportion of SH groups appears in solns. of guanidine-HCl. In order to compare the relative effects of a no. of anions, egg albumin dissolved in several guanidine salts has been studied. The max. proportion of SH groups appearing in albumin is very nearly the same in the presence of the chloride, bromide and iodide and thiocyanate of guanidine but the effect of revealing these groups begins at a lower concn. with the 3 latter salts. No SH groups appear in solns. of the sulfate and carbonate salts, and only traces in satd. solns. of the acetate. The addn. of K halides to solns. of the protein in the sulfate and carbonate salts results in the appearance of SH groups, probably because of the simultaneous presence of guanidonium and halide ions. Extensive substitution in the guanidonium radical results in a decrease in the denaturing effect of the salt so that it is possible therefore to modify the effects of guanidine salts on the one hand by varying the nature of the anion and on the other by substitution in the guanidonium cation. One definite function can be assigned to the guanidonium cation, the dissolution of the denatured protein, in this respect closely resembling the structurally closely related urea. A. P. Lothrop

Estrogens with oxygen in ring B. I. 7-Ketoestrone and 7-hydroxyestrone. W. H. Pearlman and O. Wintersteiner. *J. Biol. Chem.* **130**, 35-45(1939). Equilin, m. 237-9° (all m. ps. cor.), was converted into the acetate, and the latter was treated with OsO_4 (Serini and Logemann, *C. A.* **32**, 2539[8]), giving equilin glycol (7,8-dihydroxyestrone) (I) which had varying m.-p. ranges (crystal polymorphism). In vacuum distn. lost 1 mol. H_2O, giving *7-ketoestrone* (II), m. 212-12.5°, $[\alpha]_D^{25}$ 167° (1.13% in dioxane); *dioxime*, decompd. 252-3°; *disemicarbazone* (III), no m. p. to 295°; *enol diacetate* (IV), m. 171-1.5°. IV on hydrolysis gave II. Comparison of the absorption spectra of II, IV and *7-hydroxyestrone diacetate* (V) indicated the enol nature of IV. Wolff-Kishner reduction (Na in abs. alc. at 185°) of III gave *desoxoestrone*, m. 135.5-7°; *benzoate*, m. 172.5°. These 2 compds. were identical with those prepd. by the similar reduction of estrone semicarbazone, m. 249° (decompn.), indicating that the configuration of C atom 8 in II is the same as in estrone. Partial hydrogenation of IV, using Pt or Pd black, gave a quant. yield of V, needles, m. 122-3°, blunt prisms, m. 130-2°. Hydrolysis of V gave *7-hydroxyestrone* (VI), m. 265° (decompn.), $[\alpha]_D^{25}$ +34.5° (0.83% in dioxane); *3-monobenzoate*, m. 181°. II and VI each possessed 1/300 the estrogenic potency of estrone. D. S. Searle

The dehydration of cholesterol. J. C. Eck and Ralph L. Van Peursem. *Iowa State Coll. J. Sci.* **13**, 115-25 (1939).—The literature reports dehydration products of cholesterol with a confusing overlapping of properties.

Five products: 2,4-cholestadiene, cholesterilene, dicholesteryl ether, *a*-cholesterilene and *c*-cholesterilene should be recognized. The *a*- and *c*-cholesterilenes were found to be *d*-rotatory. Their presence as impurities in cholesterilene would explain the variable optical rotations reported for cholesterilene. A historical review, 4 pages of tabulated data and a bibliography of 65 references are included. F. E. Brown

Some reactions of α- and β-cholesteryl benzoate oxides. F. S. Spring and G. Swain *J. Chem. Soc.* 1939, 1356 9.—Cholesteryl benzoate (60 g.) in 240 cc. dry $CHCl_3$, treated with 840 cc. of 0.4 *N* BzO_2H in $CHCl_3$ and kept at 0° for 12 hrs. and at 20° for 4 days, the soln. washed with 5% Na_2CO_3 and the residue crystd. from AcOEt, gives 28 g. (46%) of *α-cholesteryl benzoate oxide* (I), m. 168 9°, $[\alpha]_D^{20}$ −31.3° ($CHCl_3$, *c* 1.12); hydrolysis with EtOH-KOH gives α-cholesteryl oxide (II). The mother liquors from I give 23 g. (38%) of the *β-isomer* (III) of I, m. 151 2°, $[\alpha]_D^{20}$ 3.8° ($CHCl_3$, *c* 2.3). 3,5,6-Trihydroxycholestane (IV) with BzCl in C_5H_5N gives a product m. 120–50°, contg. Cl, which could not be separated by crystn. IV and Bz_2O in C_5H_5N, heated on a steam bath for 9 hrs., give *5,6-dihydroxy-3-benzoyloxycholestane* (V), m. 222 3°, $[\alpha]_D^{20}$ −4.9° ($CHCl_3$, *c* 1.33); hydrolysis with MeOH-KOH gives IV. V also results from I and H_2SO_4 in C_6H_6 by refluxing 2 hrs. II (4 g.) and BzCl in C_5H_5N, heated 1 hr. on the steam bath, give 3.5 g. of *6-chloro-5-hydroxy-3-benzoylcholestane* (VI), m. 202 3° (decompn.), $[\alpha]_D^{20}$ −19.5° ($CHCl_3$, *c* 2.3); this also results from I and HCl in C_6H_6-MeOH after refluxing 30 min. Heating 1 g. VI in quinoline at 180° gives 0.5 g. of I. Treating 1 g. VI with 0.2 cc. $SOCl_2$ in C_5H_5N at 0° for 5 min. gives 0.6 g. of *6-chloro-3-benzoyloxy-4-cholestene*, m. 127 8°, $[\alpha]_D^{20}$ 79.4° ($CHCl_3$, *c* 1.03); $SbCl_3$ gives an immediate intense blue color changing to violet. III and HCl in EtOH-C_6H_6 or in $CHCl_3$, treated with HCl and refluxed 30 min., give *5-chloro-6-hydroxy-3-benzoyloxycholestane* (VII), m. 206 7° (decompn.), $[\alpha]_D^{20}$ ±0°; with BzCl in C_5H_5N, VII gives a 5-chloro-3,6-dibenzoyloxycholestane, m. 181°; this also results from β-cholesteryl oxide and BzCl in C_5H_5N. I and P_2O_5 in xylene, refluxed 2 hrs., give 8% of 6-ketocholestanyl benzoate, m. 170–1°; it also results in 10% yield by heating I and alum at 180° and 0.1 mm. for 30 min. C. J. West

Choleic acids V. Choleic acids and aliphatic hydrocarbons. Hemrich Rheinboldt, Paula Braun, Else Flume, Otto Konig and Albert Lauber. *J. prakt. Chem.* 153, 343–56 (1939); cf. *C. A.* 24, 376.—The higher members of the paraffin series readily form cryst. complexes with desoxycholeic acid (I) and apocholeic acid (II), in which they show the characteristically high coördination nos. of 6 and 8. The m. ps. show a gradual increase with the no. of C atoms and fall on a practically straight line. Other compds., such as picric acid, do not form such complexes. Undecane (III) (0.15 g.) and 2.5 g. I in 8 cc. EtOH give the *compd.* III.6I, m. 183°; III.6II, m. 181.5°. *Dodecane*-I, m. 184–5°; -II, m. 183°; *tridecane*-I, m. 186°; -II, m. 185°; *tetradecane*-I, m. 188°; -II, m. 187°; *pentadecane*-I, m. 189.5–90°; -II, m. 188.5–9° (ratio 1:8); *hexadecane*-I, m. 191.5–2°; -II, m. 190–90.5° (ratio 1:8); *pentatriacontane*-I, m. 201.5° (the system shows 2 eutectics, at about 1 and 99% I, m. 72° and 168.5° (m.-p. curves given)); -II, m. 194° (this also shows 2 eutectics, at 1 and 99% II, m. 71.5° and 168° (ratio 1:8)); *tritetracontane*-I, m. about 201° and -II, m. about 195° (m.-p. curves are given; the ratios are 1:8). *Cetylbenzene*-I, m. 189–9.5° (1:8); *p-hydroxyphenyloctadecane*-II, m. 171° (1:8) (the system shows 2 eutectics, at 8 and 98% II, m. 77° and 164°; the m. p. passes through a max. at 171° and 90% II). *Cetene*-I, m. 190° (1:8); -II, m. 189.5–90° (1:8); *13-heptacosene*-I, m. 195.5–6.5°; -II, m. 194° (1:8). C. J. West

X-ray examn. of nucleic acids and their structure (Mazza, Tappi) 3. Nitrones (Kröhnke) 25. Vegetable tannins in Formosa—casuarin, a new catechol (Osima, Ito) 29. Excitation of chain polymerizations by free radicals (Schulz) 2. Electrolytic cond. and H bridge formation (Wulff) 2. New synthetic sympatheticolytic substance [indole compd.] belonging to a chem. group of natural sympatheticolytic substances (Raymond-Hamet) 11H. Studies of chem. bond by means of Fourier analysis (Brill, *et al.*) 2.

Courtot, Ch., Doeuvre, J., Guillaumin, A., and Kipping, F. S.: Traité de chimie organique. T. XIV. Composés azotés de l'acide carbonique. Composés organo-arséniés, organophosphorés ou organosiliciés. Paris: Masson et Cie. 600 pp. Fr. 300.

Purifying hydrocarbons and derivatives thereof. David L. Yabroff (to N. V. de Bataafsche Petroleum Maatschappij). Brit. 506,574, May 31, 1939. The hydrocarbons, etc., are freed from weakly acid-reacting org. substances by extn. with an aq. alk. soln. contg. an aliphatic diamino alc. having 3, 4 or 5 C atoms, e. g., diaminoisopropanol, diamino-*tert*-butanol. Liquids treated are petroleum, C_6H_6, toluene, xylene, chloroethane, tri- or di-chloroethylene, CCl_4, chloropropane, chlorobutylene, PhCl, PhBr, nitroethane, $PhNO_2$, $AmNH_2$, $PhNH_2$, pyridine. Mercaptans, phenols and org. acids are removed by the extn. Aq. solns. of caustic alkali, NH_3, alk. earth bases, alkali metal carbonates or quaternary NH_4 bases may be used. Cf. *C. A.* 33, 7546⁸.

Liquid hydrocarbons from olefinic gases. Karl Finsterbusch (to Pure Oil Co.). U. S. 2,171,523, Sept. 5. An arrangement of app. is described, and a process for converting olefinic gases, contg. hydrocarbons having 1–4 C atoms, to liquid hydrocarbons, involving fractionating the gases under conditions of temp. and pressure suitable for sepg. the gases into a liquid portion consisting chiefly of hydrocarbons having 3 and 4 C atoms and a gaseous portion contg. the major portion of the H, CH_4, C_2H_4 and C_2H_6 present in the gases, and subjecting the liquid portion alone to heat- and pressure-type polymerization at pressures of at least 600 lb. per sq. in. and at elevated temps. suitable for polymerization of butylene and propylene to hydrocarbons of gasoline-boiling range.

Olefins. Adrianus J. van Peski (to Shell Development Co.). U. S. 2,172,228, Sept. 5. An arrangement of app. is described and a process for producing olefins from solid paraffins and highly paraffinic distillates predominating in crystallizable paraffins, which comprises vaporizing the paraffinic material without substantial cracking thereof, subjecting the vapors, by indirect application of heat thereto and in the presence of steam, to a temp. within the approx. range of 540° to 570° for 3–6 sec. and under a pressure below 75 lb. per sq. in., then promptly quenching the heated vapors to prevent continued conversion thereof, and fractionating and condensing the vapors. Cf. *C. A.* 33, 5411².

Polymerizing normally gaseous olefins. Edwin F. Nelson (to Universal Oil Products Co.). U. S. 2,170,275, Aug. 22. An arrangement of app. is described, and a process for polymerizing normally gaseous olefins such as those in cracked hydrocarbon gas mixts. contg. C_3H_6 and C_4H_8 by passing them under polymerizing conditions of temp. and pressure through successive masses of a polymerizing catalyst (such as a solid catalyst formed from kieselguhr and H_3PO_4) whose catalytic activity progressively decreases in the direction of flow of the gas therethrough.

Interpolymerization of olefins. Wm. P. Gage (to Shell Development Co.). U. S. 2,171,928, Sept. 5. An arrangement of app. is described, and a process of producing an interpolymerization product of isobutylene and a secondary butylene which involves bringing into contact a butane-butylene fraction contg. such olefins with a strong polybasic inorg. acid capable of absorbing and polymerizing the olefins under conditions at which between about 25% and about 75% of the isobutylene is absorbed by the acid without substantial isobutylene polymerization, sepg. the absorption product from the unabsorbed hydrocarbon, bringing the latter into contact with a polybasic mineral acid capable of effecting interpolymerization of isobutylene with secondary butylene at a temp. and pressure and for

on the water bath; hydrogenation with Pd-$BaSO_4$ gives III. The H_2O_2 mother liquors contain β-propylglutaric acid (*diamide*, m. 195°; *dianilide*, m. 219°). Dihydroquinidine with H_2O_2 gives V and β-ethylmethanetriacetic acid (VIII), m. 120°, $[\alpha]_D$ −1.3° (H_2O, *c* 1.006); *trianilide*, m. 280° (decompn.); *dianilide*, m. 222°. VIII was obtained in 25% yield by reacting Et α-cyanobutyrate and Et glutaconate with EtONa and hydrolyzing the crude CN ester (50% yield) with concd. HCl. C. J. West

Alkaloids of the lupines. XVIII. Synthesis of allolupinine. K. Winterfeld and F. W. Holschneider. *Arch. Pharm.* **277**, 221-37 (1939); cf. *C. A.* **33**, 3799[8].—This structural isomer of lupinine has now been prepd. and characterized. Starting with δ-chloro-γ-valerolactone, b_{14} 127-9°, the EtO deriv. was obtained by the action of abs. anhyd. NaOEt, the latter thereupon condensed with Et picolinate in C_6H_6 suspension, to *α-pyridyl α'-[δ-ethoxy-γ-valerolactonyl] ketone* (I) by the action of metallic Na. The resulting dark-brown, viscous oil, with an odor very like that of furfural, $b_{0.4}$ 173.5°, as a yellow, faintly odorous viscous oil having the compn. $C_{16}H_{19}O_3N$ (*Reinecke salt* brick-red powder, m. 128-30°; *$HgCl_2$ salt*, m. 100-2° (turbid), 116° (clear); *p-sulfonic acid phenylhydrazone*, faintly rose, m. 244-6°). Saponf., I yields *α-pyridyl α'-[δ-ethoxy-γ-hydroxybutyl] ketone* (II), $C_{12}H_{17}O_3N$, $b_{0.3}$ 140-20°, almost colorless oil becoming quickly dark in the air (*Reinecke salt*, m. 117° (decompg. 175-8°), *2,4-dinitrophenylhydrazone* bright yellow, m. 161.5°). Hydrogenated, II gives *α-[α'-piperidyl]-α,δ-dihydroxy-ε-ethoxypentane*, (III) bright-yellow viscous oil yielding the *salt* $C_{12}H_{25}O_3N.HCl.HgCl_2$, m. 129°; *Bz deriv.*, $C_{19}H_{29}O_4N$, yellow oil; *Reinecke salt*, m. 129-30°. Cyclization of III to *4-ethoxymethyloctahydropyridocoline* (IV) was effected by progressive treatment with PBr_3, NaOEt, hydrogenation via Busch/Stove, benzoylation and distn., faintly yellow thin oil, b_{11} 142-4° (*aurate*, m. 85-7°; *$HgCl_2$ salt*, m. 125-6°; *Reinecke salt*, m. 143-5°), which reduced with HI (d. 1.7) gave *allolupinine*, viscous, yellow-brown oil with hay-like odor (after standing 2 weeks needle-like crystals were deposited) (*$HgCl_2$ salt*, m. 201° (decompn.); *Reinecke salt*, m. 152-3°, *aurate*, golden-yellow oil without melination to crystallize; *picrate*, similar behavior).

Picrotoxin. IV. Ronald W. H. O'Donnell, Alexander Robertson and James C. Harland. *J. Chem. Soc.* **1939**, 1261-6; cf. *C. A.* **33**, 6861[3].—Reduction of picrotoxinin (I) with Pd-C in AcOEt ceased in 30-50 min. with the absorption of less than 50% of the theory of H. The crude non-acidic product (0.8 g. from 5 g. I) on boiling with *N* H_2SO_4 for 23 hrs. gives the *β*-dihydro deriv. (II) of I (*acetate*, m. 177°), picrotonol (III) and dihydropicrotoxic acid (IV). Since the α-isomer (V) of II is quant. converted into IV with H_2SO_4, the crude product contained both I and V. Reduction of 6 g. I in 250-35 cc. EtOH is complete in 3-6 hrs., approx. 2 mols H absorbed. The crude product on boiling with H_2SO_4 gives II, III and IV; if the EtOH soln. is evapd. to about 50 cc., 1.2-1.9 g. of II crystallizes out and the 3 g. obtained on adding H_2O to the filtrate is largely II also. The reduction product can be sepd. into a neutral and acidic fraction with $NaHCO_3$. On boiling with H_2SO_4 the neutral fraction yields II, III and IV. By repeated crystn. from EtOH some V is also isolated. The acidic fraction, boiled with H_2SO_4 and crystd. from H_2O, gives an *acid*, $C_{15}H_{29}O_6.H_2O$, m. 183° (decompn.); *di-Me ester*, m. 161°; this may be a di-HO deriv. of $Me_2CHCH.CH_2.CH_2.CHMe.CH[(CH_2)_3CO_2H].CHCO_2H$; it does not react with 2,4-$(O_2N)_2C_6H_3NHNH_2$. Reduction of I in AcOH contg. HCl ceases in 1-6 hrs. after absorption of 0.4-0.6 mole H; evapn. of the filtered soln. and crystn. from H_2O give a *compd.* m. 202°, which is a eutectic mixt. of V and the precursor (VII) of III; 5% H_2SO_4 gives III and IV. Acetylation of the crude reaction product gives a small yield of the *acetate* of V, m. 190°; boiling with *N* H_2SO_4 gives a quant. yield of III. The mechanism of the formation of VI is discussed. α- and β-Bromopicrotoxinin (VII-VIII) and the corresponding α- and β-bromopicrotoxinic acids (IX-X) cannot be hydrogenated; the absence of an ethylenic linkage is confirmed by the lack of reaction with a mixt. of O_3 and O_2. α-Picrotoxinic acid (XI) is completely hydrogenated in AcOH with a PtO_2 catalyst in 2 min.; the dihydro deriv., $C_{15}H_{20}O_7$, m. 231°. The action of O_3 on XI gives HCHO and a ketone, which on boiling with HI and red P yields norpicrotic acid and its HO deriv. and the ketone $C_{13}H_{16}O_2$. The β-isomer of XI cannot be hydrogenated nor is it oxidized by O_3. A mechanism for the formation of the satd. VII-VIII and IX-X is suggested. Treatment of I with Br in $CHCl_3$ gives a highly unstable product, which easily decomp. with evolution of HBr and on warming with H_2O gives a quant. yield of VII-VIII and HBr.

C. J. West

Sulfhydryl groups in proteins. III. The effect on egg albumin of various salts of guanidine. Jesse P. Greenstein. *J. Biol. Chem.* **130**, 519-26 (1939); cf. *C. A.* **33**, 4610[8].—The denaturation of certain proteins is characterized in part by the appearance of titratable SH groups and for all of the proteins so far investigated, the greatest proportion of SH groups appears in solns. of guanidine-HCl. In order to compare the relative effects of a no. of anions, egg albumin dissolved in several guanidine salts has been studied. The max. proportion of SH groups appearing in albumin is very nearly the same in the presence of the chloride, bromide and iodide and thiocyanate of guanidine but the effect of liberating these groups begins at a lower concn. with the 3 latter salts. No SH groups appear in solns. of the sulfate and carbonate salts, and only traces in satd. solns. of the acetate. The addn. of K halides to solns. of the protein in the sulfate and carbonate salts results in the appearance of SH groups, probably because of the simultaneous presence of guanidonium and halide ions. Extensive substitution in the guanidonium radical results in a decrease in the denaturing effect of the salt so that it is possible therefore to modify the effects of guanidine salts on the one hand by varying the nature of the anion and on the other by substitution in the guanidonium cation. One definite function can be assigned to the guanidonium cation, the dissolution of the denatured protein, in this respect closely resembling the structurally closely related urea. A. P. Lothrop

Estrogens with oxygen in ring B. I. 7-Ketoestrone and 7-hydroxyestrone. W. H. Pearlman and O. Wintersteiner. *J. Biol. Chem.* **130**, 35-45 (1939).—Equilin, m. 237-9° (all m. ps. cor.), was converted into the acetate, and the latter was treated with OsO_4 (Serini and Logemann, *C. A.* **32**, 2539[8]), giving equilin glycol (7,8-dihydroxyestrone) (*I*) which had varying m.-p. ranges (crystal polymorphism). In vacuum distn. lost 1 mol. H_2O, giving *7-ketoestrone* (II), m. 212-12.5°, $[\alpha]_D^{25}$ 167° (1.13% in dioxane); *dioxime*, decompd. 252-3°; *disemicarbazone* (III), no m. p. to 295°; *enol diacetate* (IV), m. 171-1.5°. IV on hydrolysis gave II. Comparison of the absorption spectra of II, IV and *7-hydroxyestrone diacetate* (V) indicated the enol nature of IV. Wolff-Kishner reduction (Na in abs. alc. at 185°) of III gave *desoxoestrone*, m. 135.5-7°; *benzoate*, m. 172.5°. These 2 compds. were identical with those prepd. by the similar reduction of estrone semicarbazone, m. 249° (decompn.), indicating that the configuration of C atom 8 in II is the same as in estrone. Partial hydrogenation of IV, using Pt or Pd black, gave a quant. yield of V, needles, m. 122-3°, blunt prisms, m. 130-2°. Hydrolysis of V gave *7-hydroxyestrone* (VI), m. 265° (decompn.), $[\alpha]_D^{25}$ 134.5° (0.83% in dioxane); *3-monobenzoate*, m. 181°. II and VI each possessed 1/300 the estrogenic potency of estrone.

D. S. Searle

The dehydration of cholesterol. J. C. Eck and Ralph L. Van Peursem. *Iowa State Coll. J. Sci.* **13**, 115-25 (1939).—The literature reports dehydration products of cholesterol with a confusing overlapping of properties,

Five products: 2,4-cholestadiene, cholesterilene, dicholesteryl ether, *a*-cholesterilene and *c*-cholesterilene should be recognized. The *a*- and *c*-cholesterilenes were found to be *d*-rotatory. Their presence as impurities in cholesterilene would explain the variable optical rotations reported for cholesterilene. A historical review, 4 pages of tabulated data and a bibliography of 65 references are included. F. E. Brown

Some reactions of α- and β-cholesteryl benzoate oxides. F. S. Spring and G. Swain. *J. Chem. Soc.* 1939, 1356–9.—Cholesteryl benzoate (60 g.) in 240 cc. dry $CHCl_3$, treated with 840 cc. of 0.4 *N* BzO_3H in $CHCl_3$ and kept at 0° for 12 hrs. and at 20° for 4 days, the soln. washed with 5% Na_2CO_3 and the residue crystd. from AcOEt, gives 28 g. (46%) of *α-cholesteryl benzoate oxide* (I), m. 168–9°, $[\alpha]_D^{20}$ −31.3° ($CHCl_3$, *c* 1.12); hydrolysis with EtOH-KOH gives α-cholesteryl oxide (II). The mother liquors from I give 23 g. (38%) of the *β-isomer* (III) of I, m. 151–2°, $[\alpha]_D^{20}$ 3.8° ($CHCl_3$, *c* 2.3). 3,5,6-Trihydroxycholestane (IV) with BzCl in C_5H_5N gives a product m. 120–50°, contg. Cl, which could not be sepd. by crystn. IV and Bz_2O in C_5H_5N, heated on a steam bath for 9 hrs., give *5,6-dihydroxy-3-benzoyloxycholestane* (V), m. 222–3°, $[\alpha]_D^{25}$ −4.9° ($CHCl_3$, *c* 1.38); hydrolysis with MeOH-KOH gives IV. V also results from I and H_2SO_4 in C_6H_6 by refluxing 2 hrs. II (4 g.) and BzCl in C_5H_5N, heated 1 hr. on the steam bath, give 3.5 g. of *6-chloro-5-hydroxy-3-benzoylcholestane* (VI), m. 202.3° (decompn.), $[\alpha]_D^{20}$ −19.5° ($CHCl_3$, *c* 2.3); this also results from I and HCl in C_6H_6-MeOH after refluxing 30 min. Heating 1 g. VI in quinoline at 180° gives 0.5 g. of I. Treating 1 g. VI with 0.2 cc. $SOCl_2$ in C_5H_5N at 0° for 5 min. gives 0.6 g. of *6-chloro-3-benzoyloxy-4-cholestene*, m. 127.8°, $[\alpha]_D^{20}$ −79.4° ($CHCl_3$, *c* 1.03); $SbCl_3$ gives an immediate intense blue color changing to violet. III and HCl in EtOH-C_6H_6 or in $CHCl_3$, treated with HCl and refluxed 30 min., give *5-chloro-6-hydroxy-3-benzoyloxycholestane* (VII), m. 206.7° (decompn.), $[\alpha]_D^{20}$ ±0°; with BzCl in C_5H_5N, VII gives a 5-chloro-3,6-dibenzoyloxycholestane, m. 184°, this also results from β-cholesteryl oxide and BzCl in C_5H_5N. I and P_2O_5 in xylene, refluxed 2 hrs., give 8% of 6-ketocholestanyl benzoate, m. 170.1°; it also results in 10% yield by heating I and alum at 180° and 0.1 mm. for 30 min. C. J. West

Choleic acids. V. Choleic acids and aliphatic hydrocarbons. Heinrich Rheinboldt, Paula Braun, Else Flume, Otto Konig and Albert Lauber. *J. prakt. Chem.* 153, 333–36 (1939); cf. *C. A.* 24, 376.—The higher members of the paraffin series readily form cryst. complexes with desoxycholeic acid (I) and apocholeic acid (II), in which they show the characteristically high coördination nos. of 6 and 8. The m. ps. show a gradual increase with the no. of C atoms and fall on a practically straight line. Other compds., such as picric acid, do not form such complexes. Undecane (III) (0.15 g.) and 2.5 g. I in 8 cc. EtOH give the *compd.* **III.6I**, m. 183°; **III.6II**, m. 181.5°. *Dodecane*-I, m. 184.5°; -II, m. 183°; *tridecane*-I, m. 186°; -II, m. 185°; *tetradecane*-I, m. 188°; -II, m. 187°; *pentadecane*-I, m. 189.5–90°; -II, m. 188.5–9° (ratio 1:8); *hexadecane*-I, m. 191.5–2°; -II, m. 190–90.5° (ratio 1:8); *pentatriacontane*-I, m. 201.5° (the system shows 2 eutectics, at about 1 and 99% I, m. 72° and 168.5° (m.-p. curves given)); -II, m. 194° (this also shows 2 eutectics, at 1 and 99% II, m. 71.5° and 168° (ratio 1:8)); *triletracontane*-I, m. about 201° and -II, m. about 195° (m.-p. curves are given; the ratios are 1:8). *Cetylbenzene*-I, m. 189–9.5° (1:8); *p-hydroxyphenyloctadecane*-II, m. 171° (1:8) (the system shows 2 eutectics, at 8 and 98% II, m. 77° and 164°; the m. p. passes through a max. at 171° and 90% II). *Cetene*-I, m. 190° (1:8); -II, m. 189.5–90° (1:8); *13-heptacosene*-I, m. 195.5–6.5°; -II, m. 194° (1:8).

X-ray examn. of nucleic acids and their structure (Mazza, Tappi) 3. Nitrones (Kröhnke) 25. Vegetable tannins in Formosa—casuarin, a new catechol (Osima, Ito) 29. Excitation of chain polymerizations by free radicals (Schulz) 2. Electrolytic cond. and H bridge formation (Wulff) 2. New synthetic sympatheticolytic substance [indole compd.] belonging to a chem. group of natural sympatheticolytic substances (Raymond-Hamet) 11H. Studies of chem. bond by means of Fourier analysis (Brill, *et al.*) 2.

Courtot, Ch., Doeuvre, J., Guillaumin, A., and Kipping, F. S.: Traité de chimie organique. T. XIV. Composés azolés de l'acide carbonique. Composés organo-arséniés, organophosphorés ou organosiliciés. Paris: Masson et Cie. 600 pp. Fr. 200.

Purifying hydrocarbons and derivatives thereof. David L. Yabroff (to N. V. de Bataafsche Petroleum Maatschappij). Brit. 506,574, May 31, 1939. The hydrocarbons, etc., are freed from weakly acid-reacting org. substances by extn. with an aq. alk. soln. contg. an aliphatic diamino alc. having 3, 4 or 5 C atoms, e. g., diaminoisopropanol, diamino-*tert*-butanol. Liquids treated are petroleum, C_6H_6, toluene, xylene, chloroethane, tri- or di-chloroethylene, CCl_4, chloropropane, chlorobutylene, PhCl, PhBr, nitroethane, $PhNO_2$, $AmNH_2$, $PhNH_2$, pyridine. Mercaptans, phenols and org. acids are removed by the extn. Aq. solns. of caustic alkali, NH_3, alk. earth bases, alkali metal carbonates or quaternary NH_4 bases may be used. Cf. *C. A.* 33, 7546[8].

Liquid hydrocarbons from olefinic gases. Karl Finsterbusch (to Pure Oil Co.). U. S. 2,171,52[illegible], Sept. 5. An arrangement of app. is described, and a process for converting olefinic gases, contg. hydrocarbons having 1–4 C atoms, to liquid hydrocarbons, involving fractionating the gases under conditions of temp. and pressure suitable for sepg. the gases into a liquid portion consisting chiefly of hydrocarbons having 3 and 4 C atoms and a gaseous portion contg. the major portion of the H, CH_4, C_2H_4 and C_2H_6 present in the gases, and subjecting the liquid portion alone to heat- and pressure-type polymerization at pressures of at least 600 lb. per sq. in. and at elevated temps. suitable for polymerization of butylene and propylene to hydrocarbons of gasoline-boiling range.

Olefins. Adrianus J. van Peski (to Shell Development Co.). U. S. 2,172,228, Sept. 5. An arrangement of app. is described and a process for producing olefins from solid paraffins and highly paraffinic distillates predominating in crystallizable paraffins, which comprises vaporizing the paraffinic material without substantial cracking thereof, subjecting the vapors, by indirect application of heat thereto and in the presence of steam, to a temp. within the approx. range of 540° to 570° for 3–6 sec. and under a pressure below 75 lb. per sq. in., then promptly quenching the heated vapors to prevent continued conversion thereof, and fractionating and condensing the vapors. Cf. *C. A.* 33, 5411[2].

Polymerizing normally gaseous olefins. Edwin F. Nelson (to Universal Oil Products Co.). U. S. 2,170,275, Aug. 22. An arrangement of app. is described, and a process for polymerizing normally gaseous olefins such as those in cracked hydrocarbon gas mixts. contg. C_3H_6 and C_4H_8 by passing them under polymerizing conditions of temp. and pressure through successive masses of a polymerizing catalyst (such as a solid catalyst formed from K, selguhr and H_3PO_4) whose catalytic activity progressively decreases in the direction of flow of the gas therethrough.

Interpolymerization of olefins. Wm. P. Gage (to Shell Development Co.). U. S. 2,171,928, Sept. 5. An arrangement of app. is described, and a process of producing an interpolymerization product of isobutylene and a secondary butylene which involves bringing into contact a butane-butylene fraction contg. such olefins with a strong polybasic inorg. acid capable of absorbing and polymerizing the olefins under conditions at which between about 25% and about 75% of the isobutylene is absorbed by the acid without substantial isobutylene polymerization, sepg. the absorption product from the unabsorbed hydrocarbon, bringing the latter into contact with a polybasic mineral acid capable of effecting interpolymerization of isobutylene with secondary butylene at a temp. and pressure and for

a time at which substantial interpolymerization of the unabsorbed isobutylene takes place, and treating the remaining secondary-butylene-contg. hydrocarbon with the previously sepd. isobutylene absorption product at a temp. and for a time at which interpolymerization between the isobutylene and the secondary butylene is effected. Cf. *C. A.* **33**, 5866[1].

Tertiary aliphatic amines. Bruno Christ (to I. G. Farbenind. A.-G.). U. S. 2,170,740, Aug. 22. See Ger. 673,017 (*C. A.* **33**, 6874[9]).

Stabilizing aldehydes. Joseph A. Wyler (to Trojan Powder Co.). U. S. 2,170,625, Aug. 22. Aq. solns. of aldehydes such as acetaldehyde are stabilized by addn. of a minor proportion of an oxalate, e. g., that of Na or Cu.

Unsaturated aliphatic aldehydes. Carl T. Kautter (to Röhm & Haas Co.). U. S. 2,171,727, Sept. 5. An unsatd. aliphatic aldehyde such as β-methylacrolein is prepd. by oxidizing the corresponding unsatd. alc. such as β-methylallyl alc. with use of SeO_2 or selenious acid (suitably with heating to 90°).

Mixed organic acid esters of cellulose such as mixed cellulose acetate-oleate, -linoleate or -stearate, suitable for precipitation and washing with water. Carl J. Malm and Gordon D. Hiatt (to Eastman Kodak Co.). U. S. 2,172,250, Sept. 5. A cellulose compd. contg. free and esterifiable hydroxyl groups, such as an acetone-sol. cellulose acetate, is esterified with a reaction mixt. comprising chloroacetic anhydride, an aliphatic acid contg. at least 6 C atoms, such as stearic acid, in an amt. near to but not more than sufficient to combine with the free hydroxyl groups of the cellulose compd., an inert low-boiling solvent such as methylene chloride and an esterification catalyst such as *p*-toluenesulfonic acid, and the cellulose ester formed is subsequently sepd. by pptn. in water.

Alkoxyacetones. Henry C. Chitwood (to Carbide and Carbon Chemicals Corp.). U. S. 2,170,855, Aug. 29. For the production of an alkoxyacetone such as ethoxyacetone, the vapors of an alkoxyisopropanol such as ethoxyisopropanol are brought into contact in a heated reaction zone with a dehydrogenating catalyst such as one contg. Ag oxide (suitably at a temp. of about 260°). Various examples with details are given.

Mercaptothiazolines. Roger A. Mathes (to B. F. Goodrich Co.). U. S. 2,170,059, Aug. 22. A process for producing a heterocyclic mercapto compd. embodying a ring consisting of at least 3 C atoms, 1 N atom and 1 S atom, one C atom of the ring being directly between the N and S atoms and joined to the S of the non-nuclear mercapto group, such as 2-mercapto-5-methylthiazoline, comprises interacting an amino alkyl sulfuric acid in which the amino group and the sulfuric acid group are sepd. by from 2 to 3 C atoms, such as 2-amino-1-methylethylsulfuric acid, and CS_2 in the presence of an alkali such as aq. NH_3.

Organic cyano compounds. Norman D. Scott and Joseph F. Walker (to E. I. du Pont de Nemours & Co.). U. S. 2,171,869, Sept. 5. An alkali metal addn. product such as Na naphthalene is treated with an aliphatic nitrile having a replaceable H atom such as acetonitrile, in an activating solvent such as dimethyl ether, and the product is subjected to further reaction, as with BuBr for the production of capronitrile or with benzyl chloride for the production of dibenzoacetonitrile.

Reducing cyclic carbonyl compounds to corresponding hydrocarbons. Erich Clar (to E. I. du Pont de Nemours & Co.). U. S. 2,172,020, Sept. 5. Reactions such as the reduction of benzophenone to diphenylmethane and tetraphenylethylene are effected by heating the initial material with Zn dust and $ZnCl_2$ at a reduction temp. (which may be about 290°) and the hydrocarbons produced are isolated from the resulting reaction mass, as by distn. and use of HCl and use of solvents.

Alkali metal derivatives of organic compounds. Norman D. Scott, Virgil L. Hansley and Joseph F. Walker (to E. I. du Pont de Nemours & Co.). U. S. 2,171,867, Sept. 5. At least one H atom of an org. compd. such as aniline, fluorene or *tert*-BuOH is replaced by an alkali metal atom by reaction with an alkali metal addn. compd. of a polycyclic aromatic hydrocarbon such as a Na addn. compd. of naphthalene in an activating solvent such as dimethyl glycol ether. Various examples and details of similar reactions are given. U. S. 2,171,868 (Norman D. Scott and Joseph F. Walker; to same assignee) relates to a like use of Na naphthalene or the like in reactions such as that with C_2H_2, heptyne or the like, to form products which may be further treated with CO_2, etc.

Stabilized diazo salts. Wallace A. Erickson (to E. I. du Pont de Nemours & Co.). U. S. 2,171,976, Sept. 5. A process of prepg. a stabilized product comprises forming a diazo-salt complex by adding to an acid aq. soln. of a diazo salt, such as that from *p*-nitro-*o*-anisidine, an agent such as $ZnCl_2$ capable of pptg. from the soln. a stable addn. product of the diazo salt, forming a moist paste by removing from the ppt. the major part of the resulting aq. soln., dissolving tarry substance and the moisture of the paste by adding an excess of acetone to the paste, removing the major part of the dissolved material by sepg. the acetone soln. until a second paste is formed, and then sepg. a residue of water and acetone from the second paste.

Trialkyl lead salts of nitrophenols. Mario S. Altamura (to Socony-Vacuum Oil Co.). U. S. 2,171,423, Aug. 29. Silica gel is used as a catalyst in prepg. a trialkyl Pb salt of a nitrophenol by the direct reaction between tetraalkyl Pb such as Et_4Pb and a nitrophenol such as picric acid (suitably by slowly heating to 60° in C_6H_6).

Alkyl sulfates. Egi V. Fasce and John J. Owen (to Standard Oil Development Co.). U. S. 2,170,401, Aug. 22. See Can. 380,221 (*C. A.* **33**, 3816[1]).

Organic acids. Joseph F. Walker (to E. I. du Pont de Nemours & Co.). U. S. 2,171,871, Sept. 5. For the production of an org. acid such as phenylacetic acid, a Na addn. compd. such as that of naphthalene is treated with a compd. such as phenylacetic acid in an activating solvent such as dimethyl glycol ether and the product is further treated with CO_2.

Dehydrating acetic, propionic, butyric and other lower aliphatic acids. Donald F. Othmer (to Tennessee Eastman Corp.). U. S. 2,170,834, Aug. 29. App. is described, and a continuous process of dehydrating aq. solns. of the acids by distn. in the presence of various specified ketones or ethers, sepn. of the last part of the water from the acid by straight rectification using the same vaporous heat which is thereafter passed to the azeotropic distn. and keeping the ketone or ether used out of the resulting dehydrated acid. Cf. *C. A.* **33**, 6348[4].

Propionic acid. Donald J. Loder (to E. I. du Pont de Nemours & Co.). U. S. 2,170,825, Aug. 29. EtOH is treated with CO in the presence of BF_3 and water, as the catalyst, at 125-180° and under a pressure of over 25 atm. (suitably 800-900 atm. at 135-165°). Cf. *C. A.* **33**, 996[1].

Purifying naphthenic acids. Harold G. Reiber (to Union Oil Co. of Calif.). U. S. 2,170,506, Aug. 22. A process of purifying crude naphthenic acids contg. phenols and oil, in which the acids are dild. with a low-boiling water-immiscible solvent such as gasoline, treated with H_2SO_4 and recovered by extn. in the form of naphthenate soap from the solvent contg. dissolved oil and phenols by the addn. of alkali to the treated naphthenic acids, includes the step of controlling the amt. of alkali added to the treated naphthenic acids so that the alkali is insufficient in amt. to convert the phenols present into phenolates.

Carbocyclic acids of the cyclopentanopolyhydrophenanthrene series. Max Bockmühl, Gustav Ehrhart and Heinrich Ruschig (to Winthrop Chemical Co.). U. S. 2,171,959, Sept. 5. Compds. such as acetoxypregnenolones, by oxidation of their acetyl radicals with an oxidizing agent such as a hypohalite or chromic acid, yield carboxylic acids of white cryst. character, insol. in water, sol. in alc. and which may be used as intermediates for further synthesis. Several examples with details of procedure are given.

Aliphatic acid anhydrides. Gwyn Benson (to Shawinigan Chemicals Ltd.). U. S. 2,170,002, Aug. 22. An anhydride, such as Ac_2O, is obtained by passing O into the

corresponding aldehyde in the presence of an oxidation catalyst such as Mn acetate and an inert ester diluent such as EtOAc (suitably under pressure at about 50°) and the anhydride produced is sepd.

Removing sulfur and sulfur compounds from anhydrides such as acetic anhydride. Herbert E. Martin (to Celanese Corp. of America). U. S. 2,170,972, Aug. 29. A process suitable for reducing the content of S and labile organo-S compds. in an anhydride, such as Ac_2O for use in cellulose acetylation, from 60–100 parts per million to less than 10 parts per million, involves treating the material with $Ca(OCl)_2$ in the presence of an acetate such as NaOAc and distg. under reduced pressure.

Chlorinating methane. Harry Bender (to Dow Chemical Co.). U. S. 2,170,801, Aug. 29. An arrangement of app. is described, and a process of chlorinating methane without formation of free C which involves passing a mixt. of CH_4 and Cl through an elongated channel between 2 graphite surfaces substantially free of metals, one of which is maintained at a temp. of about 360°, and which are only about 0.03 in. apart to prevent ignition of the gas and produce a product such as CCl_4.

Methoxyacetaldehyde. Nathan L. Drake (to Carbide and Carbon Chemicals Corp.). U. S. 2,170,854, Aug. 29. This compd., a mobile liquid, miscible with water, b_{770} 92.3°, and having a sp. gr. of about 0.98, suitable for use in making methoxyacetic acid, is produced by passing vapors of the monomethyl ether of ethylene glycol into contact with a dehydrogenating catalyst in a reaction zone maintained at a temp. of about 300–425°. Cf. *C.* 11. **33**, 9327[6].

Ethylene oxide. Herbert Langwell and Herbert M. Stanley (to Distillers Co. Ltd.). U. S. 2,172,025, Sept. 5. A process for mfg. ethylene oxide by oxidation of ethylene involves removing the ethylene oxide from the remaining oxidation products by adsorption on active C, treating the C for the removal of the adsorbed ethylene oxide therefrom, drying the C to make it fit for re-use and repeating the foregoing operations until the C has become partially inactive, and then revivifying the partially inactive C by treating it with hot water for a prolonged period, and finally removing the C from the water and completely drying it. Cf. *C. A.* **33**, 5869[4].

Determining the purity of trimethylamine. Le Roy U. Spence (to Röhm & Haas Co.). U. S. 2,171,809, Sept. 5. An arrangement of app. is described, and a process for controlling the amt. of basic impurities during the purification of a trimethylamine, which comprises continuously analyzing the purified product by forming a satd. soln. of the trimethylamine in a countercurrent absorbing system at a temp. at which the trimethylamine is less sol. than the basic impurities, reducing the temp. of the soln., passing it continuously through a cond. cell, measuring the elec. cond. of the soln. and regulating the flow of the trimethylamine from the purification app. in accordance with the measurements.

Isobutane. Robert F. Ruthruff (to Standard Oil Co. of Ind.). U. S. 2,172,146, Sept. 5. A process of producing isobutane from satd. petroleum naphthas b. above 125° involves heating with $AlCl_3$ to above 38° but below 205° (suitably at about 95°) and adding HCl to the mixt. to promote the reaction, the heating being continued for a time sufficient to form a gaseous product consisting mainly of isobutane which is recovered.

Melamine. Gustave Widmer and Willi Fisch (to Soc. pour l'ind. chim. à Bâle). U. S. 2,170,491, Aug. 22. See Brit. 502,148 (*C. A.* **33**, 3350[8]).

Transformation of *d*-tartaric acid into meso-tartaric acid by the action of the pancreas. Mario Betti and Elio Lucchi. *Ricerca sci.* **10**, 463–4 (1939).—See *C. A.* **33**, 6423[6]. W. F. Bruce

Cloud-chamber investigations into post-mortem ions. R. A. Watters and Wm. B. Johnston. *William Bernard Johnston Foundation Biophys. Research, Bull.* **3**, 51 pp. (1939).—Gases liberated by chem. reactions occurring in animal tissues after death contain ionized mols. capable of effecting condensation of moisture in a supersatd. atm. This was demonstrated by killing small animals in a specially constructed cloud chamber. It is suggested that the mols. serving as cloud nuclei are acted upon in some manner, possibly by short-wave radiations, before their release from the specimen. This supposition is suppo. ted by the fact that the CO_2 liberated by fermenting yeast leaves the surface as nuclei of minute water droplets the elec. charge of which can be demonstrated by means of an electrostatic field. A. W. Dox

Serum albumin. I. Preparation and properties of crystalline horse serum albumin of constant solubility. T. L. McKeekin. *J. Am. Chem. Soc.* **61**, 2884–7 (1939).—Carbohydrate-free crystd. serum albumin has been sepd. into 2 fractions by crystg. the sulfates from water. Evidence that this albumin has been sepd. as a chem. individual is obtained from the fact that the soly. in salt soln. of the protein regenerated from the insol. albumin sulfate was found to be essentially independent of the amt. of protein in the system, and of the vol. of solvent with which it was equilibrated. **II. Identification of more than one albumin in horse and human serum by electrophoretic mobility in acid solution.** John A. Luetscher, Jr. *Ibid.* 2888–90.—At pH 4.0, where a fraction of horse-serum albumin crystallizes as a sulfate, the protein exhibits 2 boundaries in the Tiselius electrophoresis app. These boundaries migrate, resp., with mobilities of 6.80 and 6.44 $\times 10^{-5}$ sq. cm./v.-sec. in acetate buffers of $\Gamma/2$ 0.02. Human-serum albumin also consists of at least 2 components migrating with velocities of 7.25 and 5.95 $\times 10^{-5}$ sq. cm./v.-sec., resp., under the above conditions. In normal serums, the faster moving component constitutes nearly two-thirds of the albumin, but in certain pathol. conditions in man, both serum and urinary albumins show a greater migration of the faster component, leaving the slower component preponderant. A. B. Garrett

Invertase inhibitors. Emil Baur. *Helv. Chim. Acta* **22**, 1114–20 (1939); cf. *C. A.* **33**, 7832[8].—Yeast autolyzate preserved with toluene was buffered to pH 4.5 with KH_2PO_4 and the inversion rate curves of sucrose in the presence of various compds. were plotted. Some inhibiting action was found for a great variety of compds. including methylene blue, acridine yellow and various other dyes, aniline, naphthylamine derivs., allylthiourea and barbiturates. The mechanism of the inhibition is uncertain and in most cases the action was weaker than that of the same compds. on oxidases. L. E. Gilson

Recent advances in science: Biochemistry. W. O. Thermack. *Science Progress* **34**, 320–8 (1939); cf. *C. A.* **33**, 4270[6].—A review of recent researches on (*a*) the amino acids of the proteins of cancerous tissue, (*b*) the role of glutamic acid in amino acid metabolism and (*c*) the citric acid cycle and cell oxidation. Joseph S. Hepburn

Chemistry and the medical technician. Colette Corbett. *J. Chem. Education* **16**, 471–5 (1939). E. H.

The effect of zinc and other metals on carboxylase. K. Lohmann and A. J. Kossel. *Naturwissenschaften* **27**, 595–6 (1939).—After washing in alk. Na phosphate soln. carboxylase from dried brewers' yeast requires aneurine diphosphate and Mg or Mn ions for activation; after washing in acid K phosphate the yeast can hardly be inactivated. In low concns. Zn (5×10^{-6} to 5×10^{-3} millimole in 1.7 cc.) inhibits the enzyme, in higher concns. (up to 2×10^{-2}) it is activated, still higher concns. inhibit reversibly. The Zn effect is especially pronounced in acid-washed yeast. In maceration juice the reactivation surpasses the

initial inhibition. In acid-washed yeast an optimum Mn addn. compensated the Zn effect, in the end Mn and Zn act additively, Cd, Ni and Co act like Zn to a lesser extent, Mg, Mn and Fe act only to increase activity, Cu, Hg, Ag, Au more than Al, Cr more than Be, Pb and Sr and least of all Ba, act as inhibitors. It is believed that Zn has a role in carbohydrate metabolism; it influences sugar fermentation by maceration juice; it inhibits lactic acid formation by aq. muscle ext. B. J. C. van der Hoeven

Biochemistry of glutathione. VIII. Method of microdetermination of glutathione in tissue by Okuda and Ogawa and its modification by Huzita and Numata. Masayoshi Ogawa. *J. Agr. Chem. Soc. Japan* **15**, 1–7 (1939); cf. *C. A.* **33**, 4622², 8667⁵.—The reduction of the oxidized form of glutathione by H_2S was nearly as effective as that by Zn dust. The iodate titration value of the reduced form of glutathione in the tissue ext., which was corrected by means of ascorbic acid oxidase treatment, gave higher results compared with that of 2,6-dichlorophenolindophenol in the case of dry beer yeast. **IX. Effect of glutathione on fever.** *Ibid.*, 182–92.—Rabbits became feverish upon the intravenous injection of glucose. The body temp. of the feverish rabbits was lowered to the normal level by intravenous injection of glutathione or cysteine-HCl. The rabbits were cured of fever by 0.5 mg. of glutathione per kg. of body wt. With hypodermic injection, about 2.0 mg. of glutathione per kg. of body wt. were required. **X. Effect of glutathione on fever and glucolysis.** *Ibid.* 775–82.—Rabbits became feverish through hyperglucemia produced by the intravenous injection of glucose. The blood-sugar content and the body temp. rose to the max. at 2–3 hrs. after the injection and then dropped to the normal level after 5–6 hrs. When 0.5 mg. of the reduced form of glutathione per kg. of body wt. was administered intravenously, the amt. of blood sugar decreased and the body temp. dropped to the normal level after about 3–4 hrs. The blood-sugar content and the body temp. were almost const. when glutathione was injected alone. The contents of reduced and oxidized blood glutathione were not affected throughout the expt. In *Bull. Agr. Chem. Soc. Japan* **15**, 4–5, 20, 122–3 (1939) (in English). Y. Kihara

Action of arginase on canavanine and arginine. III. Matunosuke Kitagawa. *J. Agr. Chem. Soc. Japan* **15**, 267–79(1939); cf. *C. A.* **33**, 2545². —The action of arginase was retarded by canaline and ornithine. The retardation of arginase was more noticeable by canavanine than by arginine. Urea did not affect the activity of arginase. Arginase was impeded by some amino acids. *dl*-α-Aminovaleric acid was especially toxic, perhaps because of the combination of amino acid with arginase. Fat acids, acyl derivs. and esters of α-amino acids had no effect on the action of arginase. The retardation of arginase increased with pH value in the case of canavanine, while it decreased in the case of arginine. The combination of amino acid with arginase was proved by detn. of the dissocn. const. Y. Kihara

Influence of monochromatic lights on enzyme action. XII. Influence of ultraviolet rays on enzyme action. 1. Yeast invertase. Reitaro Murakami. *J. Agr. Chem. Soc. Japan* **15**, 291–6(1939).—"Vim ray" blue lamp was used as the light source. The action of yeast invertase was retarded by the ultraviolet ray of 3565–3984 A. and somewhat accelerated by the visible ray of 4100–5500 A. **XIII. Influence of ultraviolet rays on enzyme action. 2. Amylase.** *Ibid.* 296–9.—The action of yeast amylase was retarded by ultraviolet rays, but was accelerated by the visible ray on the ray contg. both the ultraviolet and visible rays. **XIV. Influence of ultraviolet rays on enzyme action. 3. Yeast proteinase.** *Ibid.* 377–9.—The action of yeast proteinase was accelerated more by ultraviolet ray than by visible rays. **XV. Influence of ultraviolet rays on enzyme action. 4. Yeast lipase.** *Ibid.* 380–1.—The action of yeast lipase was accelerated more by ultraviolet rays than by visible rays. **XVI. Influence of ultraviolet rays on enzyme action. 5. Yeast catalase.** *Ibid.* 382–4.—The action of yeast catalase was retarded by ultraviolet rays, but it was accelerated by visible rays. **XVII. Influence of infrared rays on enzyme action. 1. Yeast invertase.** *Ibid.* 435–7.—Infrared rays less than 8000 A. accelerated the action of yeast invertase. The action was greater with rays contg. both visible and infrared ray. **XVIII. Influence of infrared rays on enzyme action. 2. Yeast amylase.** *Ibid.* 437–9.—Yeast amylase was also stimulated by infrared rays and especially by rays contg. both visible and infrared rays. **XIX. Influence of infrared rays on enzyme action. 3. Yeast proteinase.** *Ibid.* 439–41.—The behavior of yeast proteinase toward infrared rays was also similar to that of yeast amylase. **XX. Influence of infrared rays on enzyme action. 4. Yeast lipase.** *Ibid.* 441–2.—The action of yeast lipase was promoted by infrared rays but not so much as by rays contg. both visible and infrared rays. **XXI. Influence of infrared rays on enzyme action. 5. Yeast catalase.** *Ibid.* 442–4.—The action of yeast catalase was the same as that of lipase. In *Bull. Agr. Chem. Soc. Japan* **15**, 45–6, 79–81, 92–4(1939) (in English). Y. Kihara

Absorption spectrum of the vitellin prepared from the yolk of loggerhead turtle eggs. Kinsuke Kondo, Masao Nagasima and Siniti Morisige. *J. Agr. Chem. Soc. Japan* **15**, 737–43(1939).—The yolk of loggerhead turtle eggs, *Caretta olivacea*, was extd. with 10% NaCl soln. and 0.025 *N* NaOH. Four kinds of vitellin were fractionated. These proteins contained 2.0–2.3% of tryptophan and 5.6–5.9% of tyrosine. The yolk has a high nutritive value as it is rich in tryptophan, tyrosine and lipoids. The absorption spectrum may be affected not only by the contents of cyclic amino acids, but also by the method of the prepn. of vitellin. Y. Kihara

The production of cozymase preparations in enzyme experiments. Amandus Hahn, H. Gerstenberger and E. Mehler. *Z. Biol.* **99**, 457–61(1939).—The prepn. of cozymase entailed (1) pptn. of yeast with CCl_3CO_2H, (2) sepn. of impurities from the filtrate with Pb acetate, (3) removal of the cozymase with $Hg(OAc)_2$ according to Warburg's method and then decompg. the Hg compd. with H_2S. After filtration of the HgS, a crude cozymase product is pptd. from the filtrate with MeOH. $CuCl_2$ can be used for purification and the free cozymase obtained by pptn. from soln. with alc. and ether. F. Krasnow

The compounds between phosphatides and basic proteins. Erwin Chargaff and Morris Ziff. *J. Biol. Chem.* **131**, 25–34(1939); cf. *C. A.* **32**, 9110⁹.—Cephalin forms insol. compds. with thymus histone between pH 2 and 7 and with globin below pH 4. Lecithin forms compds. with histone only between pH 7 and 8 but does not react with globin. These compds. are apparently true salts. The basic proteins act as inhibitors of blood clotting while globin has been found to be devoid of anticoagulant action *in vivo* and the ability of the basic proteins to ppt. cephalin at a physiol. pH parallels their inhibitory effect on blood coagulation in a remarkable manner: protamines and histones, in contrast to globin, form insol. cephalin salts at pH 7. These findings supply strong confirmation of the concept that the anticoagulant effect of protamines can be ascribed to their reacting with cephalin which forms a part of the thromboplastic factor. Cephalin (but not lecithin) also forms salts with the basic dyes, methylene blue and thionine (Lauth's violet) but these derivs. are not useful for preparatory purposes because the compds. are so stable that it is almost impossible to recover the phosphatide. **The reaction between cephalin and hemoglobins.** E. Chargaff, M. Ziff and Bruce M. Hogg. *Ibid.* 35–44.—The addn. of neutral emulsions of purified cephalin to solns. of oxy- and CO-hemoglobin brings about a rapid disappearance of the specific absorption bands, disrupting the heme-globin linkage in the following manner: oxyhemoglobin + cephalin ⇌ cephalin-globin + hematin. Hemoglobin, on the other hand, is resistant to rupture. Lecithin emulsions are without effect, another instance of the fundamental biol. difference between cephalin and lecithin. The mechanism of the reaction is discussed. A. P. Lothrop

The separation of cathepsin from malignant and normal rat tissue. Mary E. Maver. *J. Biol. Chem.* **131**, 127–34

(1939); cf. *C. A.* **29**, 5915⁵.—The catheptic enzyme is assocd. with the globulin fraction present in tissue ext. and practically all the proteinase activity is pptd. by 40% satn. with $(NH_4)_2SO_4$ (28 g. per 100 cc.). Most of the enzyme is liberated upon incubation of the globulin ppt. at 38° with citrate buffer at pH 5 in the presence of KCN or cysteine. The proteinase is pptd. in the filtrate from this slightly digested globulin fraction by full satn. with $(NH_4)_2SO_4$. It is readily sol. in H_2O and, after dialysis, can be dried *in vacuo* while frozen. The dried cathepsin is highly autodigestive. Its aq. soln. is heat-coagulable and gives a strongly pos. nitroprusside test for —SH when freshly prepd. It lacks specificity and digests the proteins of other organs as well as fibrin and hemoglobin. It has been isolated from liver and malignant tissue (Jensen rat sarcomata) by the method described. A. P. Lothrop

Autolytic changes in the protein and amino acid content of liver. James M. Luck, John Eudin and Charles C. Nimmo. *J. Biol. Chem.* **131**, 261–9(1939); cf. *C. A.* **32**, 6266².—At pH 5 the globulins (pseudo- and euglobulin) of the salt-sol. fraction serve as the principal substrate for the autoproteolytic enzymes in autolyzing liver. Accompanying amino acid liberation there is partial denaturation of some of the globulin in the salt-sol. fraction with the formation of globulin II. Addn. of KIO_3 lessens considerably the rate of autolysis after the first 2 days. At pH 7.3 globulin II serves as the principal substrate and autolysis proceeds much more slowly. Some of the globulin II disappears by conversion into more sol. globulins of the salt-sol. fraction. The liberation of tyrosine is less rapid than at pH 5 and undergoes destruction by a tyrosine-destroying enzyme which is inactive at pH 5. The proteolysis is still further lessened by the addn. of KIO_3 which itself acts by oxidizing the sulfhydryl groups present in the proteolytic enzymes. A. P. Lothrop

β-Glucuronidase. II. Factors controlling the initial velocity of hydrolysis of some conjugated glucuronides. W. H. Fishman. *J. Biol. Chem.* **131**, 225–32(1939); cf. *C. A.* **33**, 2156¹. The optimum pH is 4.3 for the hydrolysis of Na estriol glucuronidate (I) by ox spleen glucuronidase, 4.4 for Na borneol (II) and 5.0 for Na menthol glucuronidate (III). The dissocn. const. of the enzyme-substrate complex is 0.0005 *M* in the case of the hydrolysis of I, 0.01 *M* for II and 0.004 for III. The enzyme hydrolyzes I at about 3 times the rate of II and III when the conditions of pH and of substrate concn. are optimal in each case. The enzyme provides a useful agent for the assay of estriol glucuronide in urine. The much greater affinity of the enzyme for I is interesting in view of the fact that estriol glucuronide is an important constituent of living mammalian tissue while II and III do not occur normally in the animal body. A. P. Lothrop

The pK'_1 of carbonic acid in concentrated protein solutions and muscle. I. S. Danielson, H. I. Chu and A. Baird Hastings. *J. Biol. Chem.* **131**, 243–57(1939).—When concns. are calcd. as moles per kg. of H_2O, pK'_1 is found not to be significantly influenced by the presence of protein. This finding was not anticipated but, however, the fact that the value is not greatly influenced by the presence of 30% hemoglobin in red blood cells makes the present results not unreasonable. Whether or not one can apply the same value to all tissues rests, of course, on further expts. Until such data are available, however, it is believed not unreasonable to employ the value of 6.10 for pK'_1 at 38° to all tissues for which calcns. are based on concns. expressed in units of H_2O. A. P. Lothrop

The determination of peptide bonds in crystalline lactoglobulin. Rollin D. Hotchkiss. *J. Biol. Chem.* **131**, 387–95(1939).—The no. of peptide bonds in 5-times recrystd. lactoglobulin was estd. by detg. the increase of NH_2 and CO_2H groups when the protein was completely hydrolyzed by (*a*) a succession of enzymes and (*b*) boiling with mineral acid. The av. eq. wt. of peptide bonds corresponded to 115.6 g. of protein. This const. indicates that a mol. wt. unit of 288 amino acid residues is incompatible with the figure 39,000 reported for the mol. wt. of lactoglobulin. Cf. Bergmann and Niemann, *C. A.* **31**, 4350⁵. A. P. Lothrop

The activating effect of glycogen on the enzymic synthesis of glycogen from glucose-1-phosphate. Gerty T. Cori and Carl F. Cori. *J. Biol. Chem.* **131**, 397–8(1939); cf. *C. A.* **33**, 7867¹.—The enzyme, (glycogen)-phosphorylase, which catalyzes the reaction, glucose-1-phosphoric acid → glycogen + H_3PO_4, requires the presence of a minute amt. of glycogen to start activity, a concn. of 0.5 to 10 mg. %, depending on the enzyme prepn. used, being sufficient. This finding explains the differences observed between enzyme preps. from liver and from skeletal and heart muscle and brain since the liver preps. always contain glycogen. A. P. Lothrop

Phosphatases of the liver and spleen. A. Ruffo. *Arch. sci. biol.* (Italy) **24**, 399–404(1938).—The alk. phosphatases of the liver and spleen are sol. in 50% alc., while the corresponding isodynamic acid phosphatases are insol. in alc. of the same concn. The 2 enzymes are therefore different. Mg^{++} has an activating action on the alk. phosphatase (pH 6 to pH 10.5) and none on the acid phosphatase (pH 3.2 to pH 5.5). P. F. Metildi

Photochemical transformations induced by ultraviolet radiation of estrone. M. Laporta and E. La Fratta. *Arch. sci. biol.* (Italy) **24**, 452–68(1938).—The specific rotation with increased exposure to ultraviolet radiation diminishes at first rapidly, then more slowly according to a logarithmic curve. The m. p. is lowered in a rectilinear manner. The absorption spectrum in the ultraviolet of estrone and that of the product of 2-hr. irradiation differ: there is a sensible diminution of transparence between 2500 and 2700 A. and a slight shift of the max. which, while for estroue is 2795 A., for the 2-hr. irradiation product, is 2805 A. The intensity of the color reaction characteristic of phenolic OH is reduced almost to half in the irradiated product. The ketone color reaction is decreased one-fourth. The typical fluorescence changes profoundly and it is possible to obtain a product with an azure fluorescence after irradiation. From alc. solns. of irradiated substance rhombic crystals can be sepd. by concn. while there remains in soln. a brown, resinous substance which has no tendency to crystn. The estrogenic activity assayed by the Miescher, Scholz and Tschopp method (cf. *C. A.* **32**, 9230⁸) remains unchanged. P. F. Metildi

The action of cysteine, Fe^{++} and of the cysteine Fe^{++} system on alkaline phosphatase. F. Del Regno. *Arch. sci. biol.* (Italy) **24**, 532–36(1938).—Cysteine and Fe^{++} separately inhibit phosphatase activity at 0.01–0.001 *M* concn. while they activate it at 0.0001 *M* concn. The inhibition from cysteine at 0.01–0.001 *M* concn., instead of being increased, is partially removed by the presence of Fe^{++} at 0.01–0.001 *M* concn. There is no further increase in activity by Fe^{++} when added to cysteine at 0.0001 *M* concn. The actions, inhibitory or activating, are more pronounced in the dialyzed enzyme. P. F. Metildi

Structure of protein according to Bergmann. F. Cedrangolo. *Arch. sci. biol.* (Italy) **24**, 537–54(1938); cf. B., *C. A.* **32**, 7485⁴.—A review. P. F. Metildi

The esterase action of benzoylcarbinol. C. Lenti. *Arch. sci. biol.* (Italy) **25**, 254–60(1939).—$BzCH_2OH$ has no catalytic action on the hydrolysis of Me butyrate. A method of electrometric titration is described. P. F. M.

Chemical nature of emulsin. C. Malaguzzi-Valeri. *Arch. sci. biol.* (Italy) **25**, 261–9(1939).—Emulsin prepns. which can be obtained from bitter almonds by Willstätter and Csányi's method (cf. *C. A.* **17**, 1251) have an isoelec. pH of 6–1. Dialysis at the isoelec. or lower pH seps. the emulsin into an apo- and a co-enzyme which may be reunited after restoration of enzyme activity. The coenzyme is neither an amino acid nor a polypeptide. It has neither a SH and S group nor amino groups. While the holoenzyme in the anion form is stable, it splits spontaneously into coenzyme and apoenzyme when it is in the form of cation. P. F. Metildi

The action of pancreatic lipase on 2,3-dimethyl-1-stearylglycerol and on 1,3-dimethyl-2-stearylglycerol. F. P. Mazza and C. Malaguzzi Valeri. *Arch. sci. biol.* (Italy) **25**, 270–8(1939).—The method of prepn. and properties of the 2 compds. are described. Both are hydrolyzed by pancreatic lipase which sets the acid free. As an acyl

migration is not discernible, it is concluded that the enzyme can split the ester linkage of the primary and secondary alc. groups. The hydrolysis of the acyl which is bound to the primary alc. group occurs before that of the acyl from the secondary group. Though with a different rate the equil. is reached in both cases when the splitting of the substrate is 15%. P. F. Metildi

The action of hydrogen peroxide on serum proteins in relation to temperature. Mario Calcinai. *Biochim. terap. sper.* **26**, 346–56(1939).—Protein resynthesis by H_2O_2 was studied in rabbit and horse serum. The fraction precipitable with CCl_3CO_2H was either increased or decreased at 0° as well as at 37°, showing that the temp. is not the factor that causes the variations. A. E. Myer

The effect of sterilization upon sugars. J. G. Davis and H. J. Rogers. *Zentr. Bakt., Parasitenk.*, II Abt. **101**, 102–10(1939).—Autoclaving 2% solns. of carbohydrates for 30 min. at 120° is very much more destructive than a "momentary" autoclaving, which consists of raising the temp. to 120° and allowing the autoclave to cool immediately. Sucrose, starch and salicin undergo less marked change in phosphate buffer (pH 6.8) than in distd. water. All other carbohydrates tested show more change in the buffer. Glucose, lactose and maltose show a large change in optical rotation but reducing power is less influenced. Fructose and arabinose show large changes in both characteristics indicating more intense destruction. The most unstable sugars are in the following order, fructose, glucose, arabinose and lactose. Sucrose, raffinose and salicin are quite stable. Maltose, starch and esculin are in an intermediate position. John T. Myers

Electric charge of cell constituents. P. v. Lehotsky. *Arch. exptl. Zellforsch. Gewebezucht.* **23**, 84–94(1939).—Elec. charges were studied by the effect of acids and alkalies on cell areas. When the pH of the medium was 4.2, infusoria died, the pH of the nucleus and protoplasm falling rapidly. At pH 11.0, death also occurred. Protoplasm resisted change in pH better than the nucleus. Maurice M. Rath

Effect of arginase of digestive juices and glands. Masaru Kaizyu. *Tohoku J. Exptl. Med.* **36**, 153–8(1939).—Expts. on the arginase action of the pancreatic and intestinal juices of the dog, rabbit, pig and cow showed that pancreatic arginase activity was greatest in the pig and its activation by Mn was also greatest. After Mn activation, the activity of the arginase from the mucous membrane of the small intestine of the pig and dog was greatest while that of cattle was weakest. The optimal pH for arginase action is pH 9. Practically no arginase effect was found in the pancreatic juice of the dog and cat, while in the intestinal juice of the dog a definite effect (at pH 9) was found which increased upon addn. of Mn. In confirmation of observations of Edlbacher and Pinösch (*C. A.* **32**, 2155[8]), this intestinal arginase is completely inhibited by the addn. of pancreatic juice. Maurice M. Rath

Effect of acylase. VI. Action of α,δ-dibenzoylornithine in the presence of enzyme solutions from various sources. Masaru Kaizyu. *Tohoku J. Exptl. Med.* **36**, 255–7(1939); cf. *C. A.* **33**, 6574.—Rabbit, pig and fowl tissue macerates (4 cc.) were separately mixed with 10 cc. of 0.1 *N* dibenzoylornithine soln. and 6.0 cc. phosphate buffer (pH 7.5). After the mixt. was allowed to digest for 24–32 hrs. at 37°, 4 cc. of the digestion soln. was examd. for increase in acidity, and 2 cc. for amino N (cf. Utzino, Tsunoo, and Mori, *C. A.* **32**, 2156[8]). Tissue macerates (kidney, liver, spleen, pancreas, etc.) gave neg. results. Maurice M. Rath

The influence of ultraviolet rays on the healing of fractures and its relation to thyroid and parathyroid hormones. Kei-gen Tei (Kiu-won Chung). *J. Chosen Med. Assoc.* **29**, 455–64(English abstr. 27)(1939); cf. *C. A.* **33**, 5014[1].—The removal of thyroid or parathyroid glands delays the healing of fracture in rabbits. The hastening effect of ultraviolet ray on the healing is weakened if the animal is deprived of thyroid or parathyroid. S. Tashiro

The effect of ultraviolet radiation and calcium injections on the healing of fractures in splenectomized or parathyroidectomized animals. Kei-gen Tei (Kiu-won Chung). *J. Chosen Med. Assoc.* **29**, 542–52(English abstr., 36–7)(1939).—The Ca injection is beneficial in healing of fracture only in rabbits whose blood Ca is low such as in the cases of irradiated or parathyroidectomized animals, and delays the healing if blood Ca is high as in splenectomy. S. Tashiro

Preparation and bioassay of renin. W. W. Swingle, A. R. Taylor, W. D. Collings and H. W. Hays. *Am. J. Physiol.* **127**, 768–79(1939).—A fractional pptn. method, in which NaCl and $(NH_4)_2SO_4$ are used, for the extn. and purification of renin is described. The product is a nontoxic pressor protein apparently belonging to the globulin group. The protein retains its pressor properties unimpaired for long periods if kept frozen, or if "lyophiled" and kept in the dry state as a powder under vacuum. The frozen or dried material contains 4.6 mg. of solids per cc. The total N content is 15.4–15.7% of the total solids. It is nondialyzable and is pos. for all the standard protein tests. A prepn. of renin was assayed on dogs and a unit established. A renin unit is defined as the min. amt. necessary, when given intravenously over a period of 2–5 sec., to raise the mean arterial pressure of anesthetized dogs an av. of 40 mm. Hg above the starting pressure level. This unit, in terms of the prepn. used is equiv. to 0.1 mg. solid material per kg. body wt. and contained 0.016 mg. N. This renin prepn. was nontoxic even when intravenously injected in large amts. E. D. Walter

Synthesis of a high-mol. hydroxymethylfurfural deriv. [elimination in the body] (Iseki, Sugiura) **10**. Sulfhydryl groups in proteins (Greenstein) **10**.

B—METHODS AND APPARATUS

GLENN E. CULLEN

Application of the Pulfrich photometer to the determination of phosphates by the method of Fiske and Subbarow. A. D. Marenzi. *Anales farm. bioquim.* (Buenos Aires) **10**, 64–9(1939); cf. F. and S., *C. A.* **20**, 1092.—Best results are obtained with filter S 75 which has a max. absorption at 750 mμ. L. E. Gilson

Application of the Pulfrich photometer to the determination of blood magnesium. A. D. Marenzi. *Anales farm. bioquim.* (Buenos Aires) **10**, 70–5(1939).—The Mg is pptd. by the method of Briggs (*C. A.* **18**, 2183), then the P in the ppt. is detd. by a modification of the method of Fiske and Subbarow (*C. A.* **20**, 1092) with a Pulfrich photometer. L. E. Gilson

Photometric estimation of conjugated glucuronides in urine. Marcel Florkin and Roger Crismer. *Compt. rend. soc. biol.* **131**, 1277–80(1939).—The application of the previously described naphthoresorcinol reaction method (cf. *C. A.* **32**, 2406[9]) to normal and diabetic urine is described. L. E. Gilson

The determination of the pH of small quantities of liquid and circulating blood with the use of a glass electrode. A. A. Smirnov. *J. Physiol. U. S. S. R.* **26**, 305–13(in French, 313)(1939).—A description of the prepn. and application of the glass electrode to the detn. of the pH of small amts. of liquid and circulating blood as developed by American and European scientists. S. A. K.

The determination of reducing sugars by the cyanide method. B. O. Lyubin and N. D. Bukhman. *Voprosy Pitaniya* **8**, No. 2, 65–70(1939).—The method of Ionescu-Matiu (*Bull. soc. chim. biol.* **9**, 68(1927)) is the most satisfactory rapid method. For solns. contg. 0.5–2% sugars concns. of $K_3Fe(CN)_6$ and KOH of 46 g./l. are most satisfactory. S. A. Karjala

A simple colorimetric method for the estimation of vitamin A. Kokiti Osima and Siniti Itaya. *J. Agr. Chem. Soc Japan* **15**, 553–62; *Bull. Agr. Chem. Soc. Japan* **15**, 101–2(1939)(in English).—In a test tube 0.5 cc. of liver oil in $CHCl_3$ was mixed with 4.5 cc. of 20% $SbCl_3$ in $CHCl_3$. The blue color which formed was used as a standard for the estn. of vitamin A. The comparison was performed within 30 sec. The mixts. of $CuSO_4$ and $Co(NO_3)_2$ were used as color standards instead of the Lovibond tintometer. Y. Kihara

A simplified procedure for the isolation of lysine from protein hydrolyzates. Eldon E. Rice. *J. Biol. Chem.* 131, 1–4(1939).—A method is described for the prepn. of pure lysine-HCl from protein hydrolyzates by direct pptn. as lysine picrate. The method eliminates the need for special equipment and greatly reduces the labor involved and the yield and quality of the product are as high as those obtained by more complicated procedures. Histidine-2HCl can be readily prepd. from the same hydrolyzate. A. P. Lothrop 1

Electrodialysis of tissue chloride. I. The method and controls. Robert H. Oster and Emily J. Kemp. *J. Biol. Chem.* 131, 13–18(1939).—A method is described for removing chloride from animal tissues by electrodialysis which is based on the method of Joseph and Stadie (*C. A.* 32, 9132[1]) for the simultaneous detn. of chloride and total base in blood serum. Considerable change has been made in the design of the chamber and electrode vessels and in the concn. of the solns. employed. There is good agreement between the recovery of chloride from the tissues by this method and by wet ashing. A. P. Lothrop 2

The determination of coenzyme I in animal tissues. A. E. Axelrod and C. A. Elvehjem. *J. Biol. Chem.* 131, 77–84(1939).—A method is described for the detn. of coenzyme I in animal tissues based upon the principle that the addn. of varying amts. of coenzyme I to a washed yeast prepn. will produce rates of fermentation which are proportional within certain limits to the amt. of coenzyme added. It is a modification of the procedure developed by Myrbäck and v. Euler (*C. A.* 31, 4379[9]). The coenzyme I content of the blood, liver, kidney cortex, brain, gray matter and gastrocnemius muscle from the guinea pig, rat, chicken and dog and of human blood are given. A. P. Lothrop 3

Methods for the determination of submicro quantities of total nitrogen, ammonia, amino nitrogen, amides, peptides, adenylic acid and nitrates. Henry Borsook and Jacob W. Dubnoff. *J. Biol. Chem.* 131, 163–76(1939).—The methods described constitute a "system" of analysis of the common N compds. in animal and plant fluids. For any individual detn. 0.1 ml. contg. 0.0003 mg of N suffices. For the fractionation of a mixt about 2 ml. contg. about 0.5 mg. of N will permit carrying out all the detns. in duplicate. The ordinary disagreement between duplicates and the abs. error of all except the Kjeldahl detns. are under 1%. The difference between duplicates in the Kjeldahl detns. is about ±2% and the recovery of N is the same as in the macro-Kjeldahl procedure. The final procedure in all the methods is an electrometric titration with a glass electrode. All the above fractions have been detd. in duplicate in 6 different solns. in 2 normal working days and all the necessary equipment can be placed on a lab. bench 8 ft. long. The methods have been used over a period of 2 yrs. in the study of the N metabolism of plant seedlings, isolated growing pea embryos, marine invertebrate embryos and thin slices of mammalian tissue. A. P. Lothrop 4

The spectroscopic determination of cytochrome *c* and its distribution in some mammalian tissues. A correction. R. Junowicz-Kocholaty and T. R. Hogness. *J. Biol. Chem.* 131, 187(1939); cf. *C. A.* 33, 7834[8].—The cytochrome content of mammalian tissues previously reported (as γ per g. of tissue) was based upon the assumption that cytochrome contains 0.34% of Fe. Theorell (*C. A.* 33, 7830[4]) reports that cytochrome purified by electrophoresis contains 0.43 rather than 0.34% of Fe so that the results previously reported should be multiplied by 0.79 (0.34/0.43) if pure cytochrome is to be defined as that product which is purified by electrophoresis. A. P. Lothrop 5

The determination of serum total protein, albumin and globulin by the biuret reaction. Geo. R. Kingsley. *J. Biol. Chem.* 131, 197–200(1939).—Total protein is detd. by mixing fresh serum with 10% NaOH soln. in a photoelec. colorimeter tube followed by the addn. of $CuSO_4$ soln. Readings remain stable for at least 1 hr. Globulin is pptd. by 23% Na_2SO_4 soln. and the albumin is detd. in the filtrate in a similar manner. Total protein minus albumin gives the globulin. The colorimeter is standardized by dilg. pooled serum with 0.85% NaCl to give solns. of various protein content as detd. by the Kjeldahl method. A. P. Lothrop 6

The identification and estimation of hexoses in polysaccharides and glycoproteins by the carbazole method. Samuel Gurin and Dorothy B. Hood. *J. Biol. Chem.* 131, 211–23(1939).—The carbazole reaction of Dische (*C. A.* 24, 1879) has been standardized so that glucose, fructose, galactose, mannose and equimol. mixts. of such sugars can be identified by their characteristic $e_{520}:e_{420}$ ratios. The colors obey Beer's law and can be quantitatively estd. The values obtained for galactose and an equimol. glucose-mannose mixt. are nearly identical so they cannot be distinguished without aid of supplementary tests. Dog liver glycogen samples from animals fed high galactose and glucose diets were found to be identical with respect to their glucose content. Meyer's finding that the neutral polysaccharide of gastric mucin is a galactan has been confirmed. The hexose in ovomucoid is mannose and in serum mucoid galactose-mannose. Mixts. of amino acids and gelatin do not appreciably influence the absorption characteristics of the sugars but results with proteins contg. appreciable amts. of tryptophan should be interpreted with caution since fair values can be obtained only when tryptophan is present in very small amts. A. P. Lothrop 7

Colorimetric determination of ammonia with thymol-hypobromite reagent. P. Arne Hansen and Verner Nielsen. *J. Biol. Chem.* 131, 309–15(1939); cf. *C. A.* 24, 2489.—When NH_3 reacts with thymol and hypobromite, a colored compd. is formed which dissolves in isopropyl ether, forming a red soln. which can be used for a colorimetric detn. With the exception of a Pulfrich photometer no special equipment is needed. The method is semimicro and quantities ranging from 20 to 0.5 γ of ammonia N per ml. may be detd. with an error of about 1–2%. A. P. Lothrop 8

Method for quantitative evaluation of hydrogen and dehydrogenase donors in the unit of measure of a tissue substratum. Mario Calcinai. *Arch. sci. biol.* (Italy) 25, 89–99(1939).—The method is based on decolorization of methylene blue which expresses the quantity of natural donors as compared with the amt. reduced to leuco base. P. F. Metildi 9

The Pasteur-Meyerhof reaction. Giovanni Moruzzi and Maria A. Bartoli *Arch. sci. biol.* (Italy) 25, 178–88 (1939).—NaF 10^{-3} mol. which inhibits respiration 26–29% in the catalysis of methylene blue does not stop aerobic glucolysis in the same system; in fact, this increases 75%. At the level of triosephosphoric acid the sepn. of the 2 ways of glucolysis takes place (the fermentative way which results in glucolysis and the oxidative way which is respiration). P. F. Metildi 10

A new mathematical method for the evaluation of endogenous insulin secretion M. M. Miller and O. P. Allen. *Ann. Internal Med.* 13, 636–49(1939).—Voluminous instructions are given for calcg. the dosage of insulin from the blood sugar and the wt. of body soft tissue, by a modification of the method of Hartman. The findings add evidence to the conception that 1 unit of insulin will metabolize 2 g. of glucose. John T. Myers 11

The role of carbon dioxide in the resazurin test. Millard F. Gunderson and Hugh L. Templeton. *J. Bact.* 38, 483–4(1939).—The use of CO_2 accelerated the first color change from blue to mauve, but the change from blue to white was uninfluenced. John T. Myers 12

Pyrotannic acid method for determination of carbon monoxide in the blood. Humio Komatu. *J. Oriental Med.* 30, 775–83(English abstr., 191)(1939).—A 10% error usually attributed to the Sayers method (cf. *C. A.* 20, 60) can be reduced to 1%, if the standard is made up with blood of the same species, CO is first washed through KOH soln., exactly the same concn. of pyrogallol as tannic acid is used in both, the sample blood is dild. 1:20, and the standards are made up in 5% steps. S. Tachiro 13

Enzymic estimation of citric acid with indotrisulfonate as indicator. Herman Gränvall. *Kgl. Fysiograf. Sällskap. Lund, Förh.* 7, 40–79(1937)(Pub. 1938)(in English);

cf. *C. A.* **32**, 2198[8].—Extensive quant. expts. are described which indicate that indigotrisulfonate (I) has the following advantages in the enzymic titration of citric acid in biol. liquids (such as fluids of the eye and sera): In the presence of reduced ascorbic acid the values for citrate are more nearly correct than those obtained with methylene blue (II) (usually low) or with thionine (usually high). The deviations of individual detns. from the average are less than with II or thionine. With I, known amts. of citrate added to biol. fluids can be detd. with good accuracy. II or thionine is decolorized more rapidly in the light than in the dark; I decolorizes at the same rate under both conditions. Addn. of reduced glutathione to vitreous humor of the ox eye retards the decolorization of I and thionine (lowering the apparent citrate value); relatively large amts. have the same value when I is used, but small amts. (such as might normally be present) depress the citrate value very slightly if at all. The use of I has the following limitations: NaCl soln., Ringer soln. and most buffer solns. should not be used for dilns., since they strongly inhibit the reaction. The values obtained in detns. on strongly colored sera may be too high. 42 references. W. C. Tobie

List of micromethods for the detn. of Ca and phosphate (Manly) 7.

Blood-sugar test. Wm. B. Fortune (to Eli Lilly and Co.). U. S. 2,171,961, Sept. 5. A process for testing for blood sugar consists in diluting many times a small quantity of the blood to be tested, pptg. proteins present in the dild. blood with that dild. blood acidulated to an acidity at least as great as pH 4.5, and removing the pptd. proteins, alkalinizing the liquid remaining to approx. pH 10.7, reacting the alkalinized liquid with CH_2O in the presence of Na_2SO_3 to produce formose in an amt. proportional to the original sugar present in the blood, and adding a definite quantity of 2,4-dinitro-1-naphthol-7-sulfonic acid to produce a reaction with the formose which yields a coloration which by comparison with a color chart indicates the quantity of blood sugar in the blood.

Testing for albumin in urine. Wm. B. Fortune (to Eli Lilly and Co.). U. S. 2,171,962, Sept. 5. A process for testing for albumin in urine consists in diluting a fixed quantity of the urine, and adding to the dild. urine Na hexametaphosphate and an acidulating agent of the class consisting of glutamic acid hydrochloride and oxalic acid, to produce a turbidity which by comparison with a turbidity chart indicates the quantity of albumin in the urine.

Analysis of respiration gases. Per F. Scholander. U. S. 2,172,038, Sept. 5. App. is described, and a method for the examination of respiration gases comprising conveying the expiration gas in a closed system of circulation tubes into the lower part of a gas chamber, withdrawing from the upper part of the gas chamber the inspiration gas and replacing the same by the expiration gas which is introduced from below until the chamber is filled to about three-fourths of its capacity with expiration gas, recording the respiratory difference curve during the steps and then detg. the production of CO_2 by absorption of the CO_2 that has accumulated in the circuit.

C—MICROBIOLOGY

LAWRENCE H. JAMES

Function of vitamin B in anaerobic bacterial metabolism. M. Silverman and C. H. Werkman. *Iowa State Coll. J. Sci.* **13**, 107-13(1939).—Vitamin B is necessary for the anaerobic dissimilation of pyruvic acid by the heterocyclic acid bacterium *Lactobacillus mannitopoeus* and stimulates the anaerobic dissimilation of glucose, lactic acid and several other substrates by *Propionibacterium pentosaceum*. 2-Methyl-5-bromomethyl-4-aminopyrimidine-HBr and 4-methyl-5-β-hydroxyethylthiazole cannot replace vitamin B as a growth factor or as a metabolic stimulant in the enzyme system of *P. pentosaceum*. Cocarboxylase or something with a similar action was found in the ext. of several types of bacteria. F. E. B.

Pressure-aeration effects on the dissimilation of glucose by Aerobacter indologenes. M. N. Mickelson and C. H. Werkman. *Iowa State Coll. J. Sci.* **13**, 157–60(1939).—Aeration, especially under pressure, increases the yield of acetylmethylcarbinol at the expense of 2,3-butylene glycol, and increases the yield of CO_2 and AcOH at the expense of EtOH. Added AcOH is reduced in spite of increased pressure of O_2. F. E. Brown

Occurrence of acrolein as an intermediate during the fermentation of glycerol by the coli-aerogenes bacteria. Howard Reynolds, W. M. Hoehn and C. H. Werkman. *Iowa State Coll. J. Sci.* **13**, 275–7(1939).—In a medium contg. only org. salts, glycerol and dimethyldihydroresorcinol added as a fixing agent *Citrobacter freundii* yielded a relatively large quantity of (2,2-[acrylidene] bis[5,5-dimethyl-1,3-cyclohexanedione]). Other cultures of *Citrobacter* and 1 of *Aerobacter* produced this same cryst. deposit. Cultures of *Escherichia* and 2 of *Aerobacter* produced no ppt. With $CaSO_3$ as a fixing agent *Citrobacter freundii* produced pyruvic acid and AcH. F. E. B.

The effect of the concentration of mannitol upon the production of levulose by the action of Acetobacter suboxydans. E. I. Fulmer, J. W. Dunning and L. A. Underkofler. *Iowa State Coll. J. Sci.* **13**, 279–81(1939).—Increasing concns., up to 25% of mannitol, decrease the rate of production but not the final yield of levulose. Decrease of surface vol. ratios from 2.36 to 0.2 decreases the rate but not the yield in the same reaction. Concns. above 30% decrease both rate of reaction and yield. F. E. Brown

Fermentation of glucose by Plectridium tetani. H. J. Boorsma, A. R. Prévot and R. Veillon. *Compt. rend. soc. biol.* **131**, 1137–40(1939).—The organism was grown 7–10 days in broth contg. 2% of glucose. Of the glucose fermented, 13–17% of the C appeared as CO_2, 15–17% as AcOH, 28–32% as $PrCO_2H$, 11–14% as MeOH, 9–12% as EtOH and 18–24% as BuOH. Very small amts. of H_2 and lactic acid were formed, but no CH_4, AcH, Me_2CO, PrOH or $EtCO_2H$. L. E. Gilson

Study of the different radicals of the glycerol molecule with respect to the growth of various strains of human and bovine tubercle bacilli. E. Fernbach and Georges Rulher *Compt. rend. soc. biol.* **131**, 1142–5(1939).—The tubercle bacillus seems to require the entire glycerol mol. for growth *in vitro*. When the glycerol of the media was replaced by PrOH, isopropanol, inositol or ethylene, propylene or trimethylene glycol little or no growth was obtained. L. E. Gilson

Preparation and properties of toxins of B. perfringens, B. oedematiens, B. histolyticus and septic vibrios. Toxin formation in the presence of sodium pyruvate and ascorbic acid. M. Weinberg and Maylis Guillaumie. *Compt. rend. soc. biol.* **131**, 1150–4(1939).—Pptn. of the crude toxins by $(NH_4)_2SO_4$ is discussed. Addn. of Na pyruvate and K_2HPO_4 to the media increases toxin formation; ascorbic acid produces little or no increase. L. E. Gilson

Ethanol as a source of carbon for Friedlandet's bacillus M. Lévy-Bruhl and N. G. Noé. *Compt. rend. soc. biol.* **131**, 1240–2(1939).—The organism utilizes EtOH but not MeOH. The EtOH is not converted to AcOH. L. E. Gilson

Inactivation of the bacteriolysin of Actinomyces by ultraviolet rays. Maurice Welsch. *Compt. rend. soc. biol.* **131**, 1296–9(1939); cf. *C. A.* **32**, 9165[1].—The inactivation is a unimol. reaction and is effected by rays shorter than 300 mμ. L. E. Gilson

Styryl 430 and the glucose metabolism of yeast. Influence of various amounts of sodium nucleinate. Y. Pourbaix. *Compt. rend. soc. biol.* **131**, 1306–9(1939); cf. *C. A.* **32**, 6682[2], 8539[9].—After the respiration of yeast has been reduced to a low level by styryl 430 (2-*p*-aminostyryl-6-*p*-acetylaminobenzoylaminoquinoline methoacetate) the addn. of Na nucleinate to about 0.00073 *M* concn. in the medium restores the respiration to about the normal level. Under normal conditions Na nucleinate does not affect the respiration of yeast. L. E. Gilton

Anaerobiase. Ernst Maschmann. *Naturwissenschaften* **27**, 628–9(1939); cf. *C. A.* **32**, 9151[4].—Anaerobiase from

obligatory anaerobic bacteria has little proteolytic activity; clupein is very little decompd. by it. Addn. of cysteine or other SH compds. to the filtered culture increases the activity of the anaerobiase to split up casein, gelatin and clupein. Addn. of H_2S or of ascorbic acid has no effect. Purified enzyme is completely inactive, cysteine activates it for casein and gelatin decompn. but not for clupein. The latter is attacked only if the fraction removed in purification is added. The material acting as activator is thermostable and diffusible. It was assumed that anaerobiase consists of 2 enzymes, one of which requires the activator as coenzyme. Another function of the activator might be that of H transmitter in the activation of the anaerobiase by SH. The activator is present in the nutrient bouillon and is not necessarily formed by the bacteria; it is formed by yeast and occurs in the animal body (muscle, blood, liver, kidney, heart). In testing various H transmitters it was found that cozymase (diphosphopyridine nucleotide) as well as triphosphopyridine nucleotide have activator qualities for the anaerobiase-SH combination toward clupein. Nicotinic acid amide-iodoacethylate is nonactive. In gelatin, glutin and glutin peptone the activator is normally present; hence addn. of it is not required for these substances as substrates. It also follows that anaerobiase is a single enzyme. The activating substance acts as H transmitter. B. J. C. van der Hoeven

Progress in the study of the typhoid bacillus. A. J. Weil, L. S. Gall and S. Wieder. *Arc. Path.* 28, 71-89 (1939).—A general review with 133 references. Harriet F. Holmes

B. pestis antigens as prophylactic agents. H. Schütze. *Brit. J. Exptl. Path.* 20, 235-44 (1939).—Plague prophylaxis in the rat, by means of heat-killed broth vaccines, where the test dose is a large and toxic one, depends markedly on the presence in the vaccine of envelope antigen. As this antigen is more abundantly produced at higher than at lower temps., vaccines grown at 37° are more effective than those grown at 26°. In the mouse, where the test dose is a small and invasive one, the effect of envelope antigen is less pronounced. Virulent cultures do not result in more potent vaccines for either rats or mice than do avirulent ones, nor are smooth cultures more effective than rough ones, when these vaccines are killed. It has been shown that a smooth avirulent culture used in the form of a living vaccine survives longer in the guinea pig and produces a higher envelope antibody titer in the rabbit than does a rough avirulent culture. No serological distinction was established between virulent and avirulent, smooth and rough, forms. Harriet F. Holmes

Growth factors for Bact. radicicola. II. Ragnar Nilsson, G. Bjälfve and Dagmar Burström. *Lanthbruks-Hogskol. Ann.* 6, 299-326 (1938); cf. *C. A.* 32, 5429[8], 7502[9]; 33, 2170[8].—The earlier indication that the growth-stimulating principle of yeast ext. for *B. radicicola* is composed of more than 1 factor was confirmed by partial fractionation with intensive ether extn. The ether ext. (I) alone possessed slight growth-stimulating activity in KNO_3 medium, but in combination with an alc. ext. (II) of the ether-insol. residue, 1/3 to 1/2 of the activity of the customary yeast ext. was obtained. Vitamin B_1 when added with I or hydrolyzed casein produced essentially as much growth as I and II combined. The active principle of I was partially adsorbed by fuller's earth and Frankonite. Neither lactoflavin nor inositol possessed any activity for *B. radicicola* on KNO_3 or asparagine media, with or without vitamin B_1 and I. These organisms were not stimulated by the combination of pimelic acid, nicotinic acid and β-alanine, which composes the active growth complex for *Corynebacterium diphtheriae* (cf. *C. A.* 32, 2089). III. *Ibid.* 7, 51-61 (1938).—An amyl alc. ext. of yeast was prepd., which at optimum concn. yielded about 1/3 as much growth of *B. radicicola* on KNO_3 medium as the customary yeast or straw ext. An excess of the ext. produced large bacteroid-like cells which was reflected in an increase in the ratio of turbidity to cell no. The simultaneous addn. of vitamin B_1 with suboptimal concns. of the AmOH ext. also increased the size of the cells and had no influence on their growth in no. This effect of vitamin B_1, possibly because of an excess over the growth requirement supplied in the ext., indicates the importance of this growth factor for the production of naturally occurring bacteroid forms in nodules of the host plant. IV. G. Bjälfve, Ragnar Nilsson and Dagmar Burström. *Ibid.* 291-9 (1939); cf. *C. A.* 33, 4283[8].—A variety of strains of *B. radicicola* from different groups were tested for their response toward vitamin B_1. Only 3 strains, all belonging to the clover group and including the one employed in the earlier work, appeared to require this growth factor, when grown either on sucrose-straw ext. gelatin or in liquid medium with ether ext. of yeast. Two other strains from the clover group and 16 from various other groups are apparently able to synthesize vitamin B_1 if it is required. V. Ragnar Nilsson, G. Bjälfve and Dagmar Burström. *Ibid.* 301-31.—The growth-stimulating ether ext. was obtained in cryst. form and identified as succinic acid. Com. succinic acid, however, was inactive. High-vacuum sublimation of the cryst. ext. yielded a purified and inactive prepn. The minute unsublimated residue, which was insol. in abs. alc. and very slightly sol. in H_2O, was highly active; 5γ produced optimum growth of *B. radicicola* when vitamin B_1 was also added. The extent of growth was comparable to that given by the customary yeast or straw ext. The active constituent appears to be identical with Kogl's biotin with respect to stability, occurrence and soly. in ether. Biotin stimulated the growth of *B. radicicola* in dilns. of 1:100,000,000,000 to 1:2,000,000,000. Cultures given biotin had a somewhat longer induction period than those given the ext. The ext. appears to supply a trace of readily available N rather than addnl. growth factors. As evidence for this, asparagine which is more readily available than KNO_3, shortened the induction period of the cultures. Some strains of *B. radicicola* were found to have no requirement for vitamin B_1. This applied when the cultures were given either biotin or the ether ext. C. K. Horner

The variability of Eberth's bacillus in an experimental bacillus carrier. M. E. Vasil'ev. *Z. Mikrobiol., Epidemiol. Immunitatsforsch.* (U. S. S. R.) **1939**, No. 5, 47-52 (in English, 52).—A dog was infected with Eberth's bacillus through a fistula of the bile bladder. Typhoid strains isolated from the bile showed rough variants which reverted to the smooth types by way of intermediate O-forms. Short-lived biochem. variants appeared rapidly. These consisted of maltose-defective strains and strains resembling dysentery bacilli which were unable to ferment glucose, lactose, maltose, mannitol or sucrose. The reactions toward xylose and H_2S formation were unchanged. None of the strains isolated was able to produce indole. An approach in the body to an *R*-form increased the agglutinability of the cultures, which fell as a result of reversion to the *S*-forms. S. A. Karjala

Pigment production by Bac. typhi abdominalis under the influence of bacteriophage. S. S. Rotenburg. *Z. Mikrobiol., Epidemiol. Immunitatsforsch.* (U. S. S. R.) **1939**, No. 5, 61-5 (in English, 65).—A portion of the colonies on sloped agar of 3 strains of *Bac. typhi abdominalis* (I) which were treated in meat peptone broth at 37° for 1 to 2 days with bacteriophage showed the ability to produce a yellowish brown or brownish green pigment. These pigment-producing variants were identical with I in biochem. and serological properties except for a lower agglutinability and the fact that they were lysinogenic. One of the strains showed a reduced virulence toward white mice and an increased resistance toward bacteriophage. S. A. Karjala

The influence of mixed cultivation on the biology of B. dysenteriae Shiga and Bac. typhi abdominalis. S. A. Botvinik. *Z. Mikrobiol., Epidemiol. Immunitätsforsch.* (U. S. S. R.) **1939**, No. 5, 66-9 (in English, 69).—Joint cultivation of *B. pyocyaneus* (I) with *B. dysenteriae* Shiga (II) resulted in the complete suppression of the growth of II. No depressing influence of I was observed on *Bac. typhi abdominalis*. The 2-week-old mucous filtrates of I react in the same way, while nonmucous filtrates have no effect on either I or II. S. A. K.

The determination of the toxicity of B. enteritidis Gärtneri. I. I. Arkhangel'skiĭ. *Z. Mikrobiol. Epidemiol. Immunitätsforsch.* (U. S. S. R.) **1939**, No. 6, 15–21 (in English, 21).—Of 10 strains of *B. enteritidis* Gärtneri grown on spleen broth for 6 days followed by filtration through Chamberland F candles, 7 produced toxic substances capable of killing mice in 1–3 cc. doses. The toxin reacts with specific serum in flocculation tests. No uniform Schwartzmann reaction was observed in skin tests on rabbits. S. A. Karjala

Cultivation of phase I *H. pertussis* in a semisynthetic liquid medium. J. W. Hornibrook. *U. S. Pub. Health Repts.* **54**, 1847–51 (1939).—The formula of a simplified, serum-free liquid medium is given. It supports a heavy growth of Phase I *H. pertussis*. It has been demonstrated that, aside from org. N, 2 groups of substances are necessary for growth of Phase I: (*a*) certain polysaccharides, and (*b*) S-contg. compds. such as glutathione or cysteine. An unknown substance present in yeast ext. stimulates growth but is not essential. Nine references. J. A. K.

Yeasts found in "miso" (bean paste). Masatosi Mogi. *J. Agr. Chem. Soc. Japan* **14**, 951–88, 1175–1206, 1297–1324; *Bull. Agr. Chem. Soc. Japan* **14**, 80–1 (1938) (in English).—Thirty-four stocks of yeasts were isolated from various kinds of miso and investigated morphologically and physiologically. Ten varieties of *Saccharomyces miso*, 6 varieties of *Zygosaccharomyces miso*, 2 varieties of *Debaryomyces miso*, one variety of *Hansenula anomala* var. *miso*, 8 varieties of *Torulopsis miso* and one variety of *Torulopsis albida* Lodder var. *miso* were newly found. *Zygosaccharomyces* were mainly found in the kinds of miso fermented for a long period, while *Debaryomyces* were isolated from the kinds of miso fermented for a short period. Y. Kihara

Molds growing in high concentration of sulfuric acid and copper sulfate. Tatuzo Sato. *J. Agr. Chem. Soc. Japan* **15**, 359–69; *Bull. Agr. Chem. Soc. Japan* **15**, 76–7 (1939) (in English).—Three strains of molds were isolated from H_2SO_4 soln. and one strain was isolated from $CuSO_4$ soln. of Bertrand's reagent. They were, resp., *Oöspora viscosa* nov. sp., *Dematium pullulans* de Bary var. *acidiphylum* nov. sp., *Penicillium cuprophylum* nov. sp. and *Penicillium biforme* Thom var. *vitriolum* nov. var. They grew, resp., in 7% H_2SO_4, 5% H_2SO_4, 19% $CuSO_4$ soln. and 21% $CuSO_4$ soln. The optimum temps. for the growth were, resp., 28°, 30°, 28° and 28°. The optimum pH values were, resp., 5.4, 5.4, 7.6 and 4.4. They did not ferment sugars. Y. Kihara

Acetone-butyl alcohol fermentation. I. Bacteriological properties of Bacillus butanolo-acetoni Yukawa-Horie nov. sp. and the fermentation of cassava by this organism. Matao Yukawa and Sigeyosi Horie. *J. Agr. Chem. Soc. Japan* **15**, 609–23, *Bull. Agr. Chem. Soc. Japan* **15**, 103–5 (1939) (in English).—A new strain of *Clostridium acetobutylicum* (Weizmann) was isolated from maize. It was different in the fermentability of rhamnose and trehalose, the form of sporangia, and the fermentability at low temp. from *Bacillus granulobatter pectinovorum*. Hence it was named *Bacillus buanolo-acetoni* Yukawa-Horie nov. sp. About 7 kg. of acetone, 14 kg. of butyl alc. and 2 kg. of EtOH were produced by the fermentation of 100 kg. of cassava within 72 hrs. In the fermentation of cassava the addn. of rice as a source of N gave a good yield, but the rice bran was unsuitable. The max. limit for the concn. of the mash was 6–8%. In large-scale fermentation the viscosity of the starchy mash should be lowered by the addn. of a small amt. of acid before cooking. For the prevention of putrefaction by lactic acid bacteria, local heating in the sterilization of mash should be avoided, and the use of vigorous stock of acetone bacteria and shortening of the fermentation are recommended. Y. Kihara

The optimum hydrogen-ion concentration for amylase of Aspergillus oryzae. Takeo Nagatomo. *J. Agr. Chem. Soc. Japan* **15**, 753–6 (1939).—There was a deviation of the optimum pH for amylase among various strains of *Aspergillus oryzae*. Y. Kihara

Crystals occurring in the mold membrane in oxalic acid fermentation. Mituo Simo. *J. Agr. Chem. Soc. Japan* **15**, 751–2 (1939).—*Aspergillus niger* Radiumspecy IV was inoculated in a soln. contg. 15% of sucrose, 0.2% of $(NH_4)_2SO_4$, 0.1% of KH_2PO_4 and 0.025% of $MgSO_4$. After 3 days 10% of $NaHCO_3$ and 5% of CH_3COONa were added to make the soln. faintly alk. It was cultured for 15 days at 30°. Two kinds of crystals were observed in the mold membrane. They were identified as $Na_2C_2O_4$ and $NaHC_2O_4.H_2O$. Y. Kihara

Isolation of a yeast from the digestive organ of the grasshopper. Kano Ohtu and Kazuo Yamahuzi. *Bull. Agr. Chem. Soc. Japan* **15**, 30–2 (1939) (in *J. Agr. Chem. Soc. Japan* **15**, No. 3) (in German).—The yeast, easily fermented the sugar soln. The yeast was named *Saccharomyces batta* from its morphological studies. The optimum pH for the growth was 3.5–5.6, and the optimum temp. for the fermentation was 33°. The fermentation ratio was 95%. Cf. *C. A.* **33**, 7040[8]. Y. Kihara

Enzymes in young mycelia of Aspergillus oryzae. Yosio Otani. *Bull. Agr. Soc. Japan* **15**, 59–64 (1939) (in *J. Agr. Chem. Soc. Japan* **15**, No. 4) (in English).—*Aspergillus oryzae* was cultured on a synthetic soln. until sufficient growth of mycelia was obtained. The powd. mycelia were extd. with H_2O at 40° for 4 hrs. Invertase, maltase, lactase, emulsin, α-amylase, β-amylase, papain-type protease, peptide-decompg. enzyme, rennin, urease and catalase were found in the ext. The actions of peroxidase and indophenolase were weak. Y. Kihara

The bacteriological decomposition of 3,5-diiodo-1-tyrosine. Günther Habild. *Z. Biol.* **99**, 421–30 (1939).—*B. coli* strain decompd. 1-diiodotyrosine, splitting off a large part of the organically bound I. Diiodotyrosine first inhibited their growth and then killed them. A relationship seems to exist between the amt. of I split off and injury. *B. coli* cultures quickly decarboxylyzed the tyrosine formed from 1-diiodotyrosine. Frances Krashow

Mathematical representation of the course of yeast growth. R. S. W. Thorne. *J. Inst. Brewing* **45**, 472–86 (1939).—The growth curve is a logistic function (Pearl and Reed, *Proc. Natl. Acad. Sci.* **6**, 275 (1920)) in which the consts. are related to max. growth, rate of growth and seeding rate. The agreement with expt. is within ± 6%. The effects of sucrose, bios, EtOH, NH_4 phosphates and aeration on the consts. are described. Small systematic departures are probably due to acclimatization and autolysis. Quick Landis

Growth factors for bacteria. IX. Studies of a growth factor for Clostridia. D. W. Woolley, L. E. McDaniel and W. H. Peterson. *J. Biol. Chem.* **131**, 381–5 (1939); cf. *C. A.* **33**, 4285[8].—The essential growth factor for certain *Clostridia* which is found in cereal grains is an acid of low volatility, difficult to esterify and destroyed by oxidation. It is not affected by acetylation or methylation. The most active prepns. were detectable when 0.001 γ per cc. was added to an otherwise synthetic medium. Addn. of 0.1 to 0.5 γ per cc. produced max. response. Procedures for the concn. of the factor are described. A. P. Lothrop

Attenuation of granuloma-producing germs with bile and their use as vaccine. Alberto Ascoli and Antonio Bassi. *Biochim. terap. sper.* **26**, 304–17 (1939).—A highly virulent strain of bovine tuberculosis rendered harmless for calves through 80 successive cultures on bile contg. glycerol potatoes is recommended for further immunization of Calmette-Guerin bacillus vaccinated cattle. The culture on bile-contg. media is suitable to decrease the virulence of all granulomata-producing germs especially *Brucella abortus*. This organism loses its virulence within a month and can then safely be used for vaccination of cattle. A. E. Meyer

Pullulomyxa botrytis N. Sp. A. C. Thaysen. *J. Bact.* **38**, 355–66 (1939).—A description is given of the physiol. morphological and cytological characters of this organism which was isolated from decaying vegetable debris. It has previously been shown to be capable of destroying the specific polysaccharides of certain bacterial toxins. Attempts to isolate the enzyme system which destroys these polysaccharides were unsuccessful. Neither

by freezing and thawing nor autolysis could the enzymes be isolated in active form. John T. Myers

Studies on capsule formation. I. The conditions under which Klebsiella pneumoniae (Friedländer's bacillus) forms capsules. J. C. Hoogerheide and Madeline H. Harrison. *J. Bact.* **38**, 367–88(1939).—Friedländer's bacterium was grown in Ostwald viscosity tubes, and from the detns. of relative viscosity and simultaneous bacterial counts, deductions could be made as to the degree of encapsulation. The largest capsules were obtained by cultivation for about 8 hrs. at 37° in a medium contg. 1–4% of peptone and 1% glucose with an initial pH of 7.5. In the absence of sugars capsules were very small. The presence of either glucose, maltose, sucrose, or to a lesser extent pyruvate or glycerol, was necessary to ensure large capsules. Neopeptone, Witte or Bacto peptone served equally well as sources of N. In synthetic media, capsules formed only when the phosphate concn. was below the limits for optimal bacterial growth. J T. Myers

Investigations upon the antigenic relationships among the root-nodule bacteria of the soybean, cowpea and lupine cross-inoculation groups. O. A. Bushnell and W. B. Sarles. *J. Bact.* **38**, 401–10(1939).—A great no. of serological types exist among the nodule bacteria from the above species. The strains within a serological type possess antigenic constituents in common. The antigens are found in whole cells, heated cells, and washed heated cells. Some serological types are made up of strains from only one species of plant, but other types came from 2 or even 3 species. 15 references. John T. Myers

Chemical factors influencing the growth of tubercle bacilli. II. Organic reagents. Ben C. Sher and Henry C. Sweaney. *J. Bact.* **38**, 411–18(1939); cf. *C. A.* **33**, 5439².—The diaryl secondary amines investigated were uniform in their activity as inhibitors regardless of whether "C. P.," "purified" or nonsynthetic medium was used. Each of the dihydroxybenzenes and the aryl-aliphatic secondary amines was more effective in "purified" medium than in "C. P." or meat-broth medium. Some of the aryl-aliphatic secondary amines and dihydroxybenzenes were more effective in "purified" medium than were the diaryl secondary amines. In the "C. P." or meat-broth medium they were less effective. A no. of antioxidants have a tremendous inhibiting effect on bovine and in particular human strains of tubercle bacilli. The effects of oxidation-reduction potentials are being studied. John T Myers

The lack of one of the somatic antigens of typhoid cultures. Lois Almon and W. D. Stovall. *J. Bact.* **38**, 419–30(1939).—Among 170 strains of *Eberthella typhosa*, 2 showed resistance to the action of several bacteriophages which were lytic for the others. The missing antigen was not the one which *E. typhosa* shares with *S. s. hottmülleri*, but one which is normally present in *S. enteritidis*, which is antigen IX of the Kauffmann classification. John T. Myers

The Corynebacterium pyogenes antitoxin content of animal serums. Reginald Lovell. *J. Path. Bact.* **49**, 329–38(1939). John T. Myers

Amino acid utilization by different strains of staphylococci. Franz Lieb and Berta Vallender. *Zentr. Bakt., Parasitenk.*, I Abt., Orig. **144**, 528–30(1939).—All strains of pathogenic, skin and air staphylococci failed to split *d*- and *l*-valine and creatinine. All of the strains used alanine, the pathogens actively and the others sparingly. John T. Myers

Certain film-forming yeasts. L. H. Hohl and W. V. Cruess. *Zentr. Bakt., Parasitenk.*, II Abt. **101**, 65–78 (1939)(in English).—Four nonfermentative and 11 fermentative strains of yeast were studied. Detailed data are given as to alc. production; aldehyde, volatile acid and fixed acid production in wines; tolerance to alc. and SO_2; effect of temp.; carbohydrate fermentation and cell morphology are given. 35 references. J. T. M.

Specificity of aneurin for some microörganisms—action of a homolog of aneurin. W. H. Schopfer. *Ann. inst. Pasteur* **61**, 781–2(1938); cf. *C. A.* **32**, 5431⁸.—The homolog of aneurin in which there is an Et instead of a Me group in position 2 on the pyrimidine ring is very active on *Phycomyces blakesleeanus, Ustilago violarea, Rhodotorula rubra, Dematium nigrum, Parasitella simplex* and *Absidia ramosa*. For the organisms which require pyrimidine, the 2-methyl-4-amino-5-aminomethylpyrimidine can be replaced by 2-ethyl-4-amino-5-aminomethylpyrimidine. The CH_3 group in position 2 of the pyrimidine is not important. The homolog of aneurin studied is more active on Phycomyces than aneurin itself. B. Prescott

Binding power of agglutinin. I. Hemagglutinin. Hisakiti Makino. *J. Chosen Med. Assoc.* **29**, 897–922 (German abstr. 51)(1939). **II. Bacterial agglutinin.** *Ibid.* 1146–83(German abstr. 76–7). S. Tashiro

Hydrogen-ion concentration of histiocytes in their phagocytic function on Bacillus tuberculosis. Sigeru Iwata. *J. Oriental Med.* **30**, 839–50(English abstr. 253–4)(1939). —Of histiocytes found in the peritoneal cavity of mice inoculated interperitoneally with the living strains of typus humanus Frankfurth, or typus bovinus No. I, 50% is the active form (*A*), 30% normal (*B*) and 20% degenerative type (*C*), pH of *A* being 5.2–6.4, *B* 6.4–6.8 and *C* 6.8–7.6. The data for histiocytes found in the cavity injected with the other strains of the acid-fast bacilli are also given. S. Tashiro

The distribution and fate of diphtheria toxin in the rat. Ho Syo Tei. *Japan. Z. Mikrobiol. Path.* **33**, 419–33 (1939).—A considerable amt. of diphtheria toxin was found in the spleen, kidney, liver and suprarenal gland, but not so much in the testicles, brain and muscle after intravenous injection. I. S. Yun

The relationship between diphtheria toxin and reticuloendothelial system. Ho Syo Tei and Kozi Simohori. *Japan. Z. Mikrobiol. Path.* **33**, 434–43(1939).—Diphtheria toxin disappears quickly upon the blockade of the reticulo-endothelial system with 7% India ink soln. after the injection of toxin in the blood of the rat. I. S. Y.

Carter, Charles F.: Microbiology and Pathology. 2nd ed. St. Louis: C. V. Mosby Co. 755 pp.

THOMAS G. PHILLIPS

The action of phytohormones on the development of sugar-beet seedling plants. André Willam. *Sucr. belge* **58**, 461–78(1939).—Treatment of sugar-beet seedling plants with aq. solns. of vitamin B_1 (0.66 mg./l. and 0.132 mg./l.) caused no noticeable change during the first leaf stage. Vitamin B_1 (0.2 mg./l.) and heteroauxin (0.2 mg./l.) effected an increase in the size and sugar content during the second leaf stage. The size and sugar content of the seedling plant during the six-leaf stage were increased by vitamin B_1 (0.2 mg./l.) and also heteroauxin (0.1 mg./l.) and decreased by larger quantities of heteroauxin (0.2 mg./l.). Vitamin B_6 (0.5 mg./l.) produced larger plants with lower sugar contents. W. W. B.

On the disease of the sugar-beet heart and its treatment with boron. Gabriel Bertrand. *Sucr. belge* **59**, 3–8, 21–30(1939).—A review with 96 references. W. W. Binkley

Spectroscopic investigation of the state of chlorophyll in the plant, in extracts and in pure preparations. Klaus P. Meyer. *Helv. Phys. Acta* **12**, 349–93(1939).—"Native chlorophyll" exts. are obtained from leaves of *Fontinalis antipyretica* L. by grinding them first with petr. ether for 4 min. to remove carotenoids, then with abs. EtOH for 2 min. Pure $CaCO_3$ added to neutralize plant acids. Addn. of petr. ether and water to the EtOH soln. gives 2 layers, which are sepd. The petr. ether is removed by a current of pure N_2 in the absence of light below 10°. The residue is dissolved in abs. EtOH. Absorption measurements by the method of Halban, Kortüm and Szigeti (*C. A.* **30**, 7454⁵) (photoelec. null method with rotating sector) show that the absorption curve of this native chlorophyll is different from that of the usual pure chlorophyll preps. Pure chlorophyll results from native chlorophyll by aging; it is therefore a deriv. of native chlorophyll. Absorption measurements on chlorophyll in

leaves lead to quite different curves. It is possible to obtain *colloidal* chlorophyll from native chlorophyll which has the same absorption spectrum as that in the leaves. It is concluded that the native chlorophyll is identical with the chlorophyll in the plant and that all solns. thus far obtained by other authors have been degradation products of native chlorophyll. The fine structure of the colloidal chlorophyll in the chloroplasts is discussed. These results cannot be explained by a change of the compn. due to different ratios of chlorophyll a and b, in native chlorophyll and pure chlorophyll. Egon Bretscher

Action of the presence of lead on growth. Vincenzo Rivera. *Ricerca sci.* **10**, (1)61–3(1939).—Lentil seeds set to germinate in a fully enclosed paraffin-sealed glass box showed roots 10 to 12 hrs. before controls when a layer of fresh Pb filings 18 mm. thick in a cardboard box was placed on the glass cover. The sprouts likewise developed 10–15 hrs. before controls and both roots and sprouts grew longer than those of the controls. A 1-mm. layer of Pb filings had little effect. W. F. Bruce

Preliminary data on the storage of Hevea pollen. M. J. Dijkman. *Arch. Rubbercultuur* **22**, 239–59(1938).—Pollen from *Hevea* rubber trees can be successfully stored without serious loss of germinating power at least 19 days at 6° and in air conditioned over 27–35% H_2SO_4. This power is measured 1 hr. after the pollen is spread on a substratum having 10.53–12.11% glucose and 1.5% agar-agar (pH 4.5). D. E. Cable

Studies on the acidity of Western (grown) tomatoes. G. S. Bohart. *Western Canner & Packer, 29th Yearbook* **31**, No. 5, 77(1939).—The variation in pH among 15 varieties of tomatoes grown in Calif. was 4.29–4.59. There was considerable difference in the pH values of tomatoes of the same variety maturing on the same plant. Thus in Early Santa Clara variety the pH varied from 4.61 to 4.33 and in Earliana from 4.93 to 4.37. In the 2 above varieties the pH value was lower by 0.3–0.4 in fully mature fruit as compared with partially colored fruit. Green tomatoes were also somewhat more acid than either the partially or fully ripe tomatoes. C. R. Fellers

Coloring matter of the fruit of the palm Cycas revoluta. Carmela Manunta. *Helv. Chim. Acta* **22**, 1153–4(1939).—The pigment was extd. from the red fruits, sapond. and adsorbed chromatographically on CaO and on alumina. Cryst. zeaxanthin was finally obtained. The only other pigment detected was a trace of carotene. L. E. G.

Recent advances in science: plant physiology. Walter Stiles. *Science Progress* **34**, 346–50(1939).—A review of recent researches on micronutrients. J. S. Hepburn

Constitution of wood polyoses. E. Husemann. *Naturwissenschaften* **27**, 595(1939).—Wood polyoses are generally polysaccharides contg. pentoses such as xylose and arabinose, hexoses like mannose and galactose. Polymerizations detd. osmotically show for xylans from straw or beech 150, mannan from pine 160, arabo-galactan from larch 220 and cellulose from beech 1500. The polyoses can be converted into derivs. such as Bz or Ac compds. without change in polymerization degree. Viscosity detns. show that the K_m consts. of the Staudinger law which indicate the lengths of the mols. are the same for mannan, xylan and cellulose. The const. for arabo-galactan is 20 times smaller, and of the order of that of starch, indicative of strongly branched mols. It was further detd. that xylans from straw or beech contain more than 90% mols. of equal size similar to what was found by Svedberg (cf. *C. A.* **28**, 1065[2]) for certain proteins. B. J. C. van der Hoeven

Low-temperature injury to fruit blossom. I. The damage caused to fruit blossom by varying degrees of cold. C. P. Field. *Ann. Rept., East Malling Research Sta., East Malling, Kent* **26**, 127–38(1938) (Pub. 1939).—Injury of apple blossoms by low temps. (26–28°F.) was decreased considerably by injecting the blossoming shoots on the trees with 1–5% solns. of glycerol; the effectiveness of the treatment increased with the strength of the soln. Similar results were obtained by placing the ends of cut shoots in the solns. Solns. of urea or dextrose were ineffective. K. D. Jacob

Experiments with growth-controlling substances. II. Response of fruit tree cuttings to treatment with synthetic root-forming substances. H. L. Pearse. *Ann. Rept., East Malling Research Sta., East Malling, Kent* **26**, 157–66 (1938)(Pub. 1939); cf. *C. A.* **32**, 3785[6].—Numerous tests with softwood cuttings of several varieties of pear, quince, apple, plum and cherry showed that, with suitable material, root formation is accelerated and increased by immersing the ends of the cuttings for 24 hrs. in solns. (10–40 p. p. m.) of either indolebutyric acid or α-naphthaleneacetic acid. In general, indolebutyric acid caused the production of a more fibrous root system than did α-naphthaleneacetic acid. Application of a soln. of vitamin B_1 (1 mg. per l.) to the treated cuttings, 10–12 days after they were planted, did not increase the no. of cuttings that rooted, but the cuttings so treated grew on more vigorously after removal from the frames in which they were planted. No marked stimulation was obtained from the treatment of hardwood cuttings in the autumn. K. D. Jacob

Some preliminary experiments on the use of root-initiating substances in hop propagation. C. R. Bailey. *J. Southeastern Agr. Coll., Wye, Kent* No. 44, 47–53(1939).—β-Indolylacetic acid (1:10,000) and α-naphthaleneacetic acid (1:20,000) were equally effective in promoting the rooting of hop cuttings soaked therein for 24 hrs. Phenylacetic acid was less effective. K. D. Jacob

The seasonal fluctuation in the manganese content of four grass species. R. L. Wain, I. V. Hunt and G. C. Marsh. *J. Southeastern Agr. Coll., Wye, Kent* No. 44, 114–19(1939).—Throughout the yr. the av. Mn content was highest in the dry matter of creeping bent (*Agrostis alba*, var. *stolonifera* L.), intermediate in timothy (*Phleum pratense* L.) and perennial ryegrass (*Lolium perenne* L.) and lowest in red fescue (*Festuca rubra* var. *genuina* Hack.), all grown on the same soil. Analyses at approx. monthly intervals showed a marked fluctuation in the Mn content of all the species during the yr. and the period of vigorous growth coincided with low Mn content. K. D. Jacob

The chemical composition of the seed and straw of various grasses. R. Probert Davies. *Welsh J. Agr.* **15**, 250–60(1939).—There were considerable differences in the chem. compn. of the seed of the 17 species analyzed, but there appeared to be little relation between the mineral content of the seed and the type of natural habitat in which the various species flourish. The seed of the agriculturally least valuable grasses tend to be richer in crude protein, fat, P and Ca than the seed of the valuable species. The crude protein content is higher, usually much higher, than that of cereal grains. Also, the mineral content, particularly Ca, is usually higher than that of cereal grains. With the exception of Ca, the grass seeds remove smaller quantities of mineral elements from the soil per acre than do cereal grains. The chem. compn. of timothy, cocksfoot and perennial ryegrass straw is similar to that of oat straw, whereas the compn. of red fescue straw is comparable to that of wheat straw. The straw of grasses absorbs much greater quantities of mineral elements from the soil per acre than does the seed of the same species. Cocksfoot, timothy and perennial ryegrass straws take up about twice the quantity of mineral elements from the soil per acre as an av. crop of cereal straw. Grass straws require much more K per acre for their sustenance than do the cereal straws. K. D. Jacob

The formation of amino acids in green plants with nitrate as source of nitrogen. Artturi I. Virtanen and A. A Arhimo. *Suomen Kemistilehti* **12B**, 24(1939)(in English).—When the roots of growing peas or oats are placed in 2–4% KNO_3 soln. for 24 hrs. in either light or dark the presence of nitrite-N and NH_2OH can be detected in the roots. In $(NH_4)_2SO_4$ solns. NH_2OH is not formed, or is formed in amts. too small to be detected. This supports the theory previously described (*C. A.* **33**, 7024[6]) of the formation of NH_2OH by reduction. This reacts with oxalacetic acid (I) and possibly ketoglutaric acid (II) to form the corresponding oximes which are then reduced to aspartic and glutamic acids, resp. If no II is present the NH_2OH is reduced to NH_3. When NH_4^+ salts are used as the source

of N the NH_3 reacts directly with I and II with aspartic acid dehydrase and glutamic acid dehydrase, resp., as catalysts, without oxidation to NH_2OH. S. A. K.

Relation between the nitrogenous compounds of seeds of various crops and the diastatic power of their malts. IV. Barley and naked barley. Hideo Kitagiri and Naratarо Mugibayasi. *J. Agr. Chem. Soc. Japan* **15**, 309–16 (1939); cf. *C. A.* **33**, 7843⁷.—During the germination of barley and naked barley, hordein N or glutelin N changed into the sol. N, although the rate varied with the species of the seeds. The saccharifying power of the germinated barley or naked barley was parallel to the amt. of albumin of the ungerminated seeds. There was a distinct difference in the action of maltase among the species of the seeds. In *Bull. Agr. Chem. Soc. Japan* **15**, 71 (1939) (in English). Y. Kihara

Change in the contents of starch and sugar in tobacco leaves after topping. Takeo Nito and Masamiti Ota. *J. Agr. Chem. Soc. Japan* **15**, 99–103 (1939).—After topping of tobacco leaves, the starch content reached a max. at the ripening period and the sugar content gradually decreased with ripening. Change in N content could scarcely be observed. Y. Kihara

Stimulant for cane-sugar formation in plants. III. Tetutaro Tadokoro. *J. Agr. Chem. Soc. Japan* **15**, 659–60 (1939); cf. *C. A.* **33**, 9365¹.—When lumiflavin or eosin was added to Knop's soln. for the culture of maize, the contents of reducing and nonreducing sugars in the young plant increased by 2 times after 2 weeks, but the growth of roots was retarded. The phenomenon was equally observed with every substance having fluorescence. The action of catalase in the plant growing under such a condition was inferior to that in the normal plant. The difference in the action of peroxidase could not be observed. Y. Kihara

Chemical studies on the roots of Platycodon grandiflorum. VII. The molecular weight and the hydrolysis of platycodin. Magosaburo Tuzimoto and Tuneo Matumoto. *J. Agr. Chem. Soc. Japan* **15**, 690–8; *Bull. Agr. Chem. Soc. Japan* **15**, 113–14 (1939) (in English); cf. *C. A.* **33**, 6418⁸.—The mol. wt. of platycodin was 836 when platycodin alc. soln. was titrated with 0.01 *N* NaOH alc. soln. and the acidity was calcd. as monobasic acid. The mol. wt. by Barger's method was 801. The elementary analysis coincided with the formula $C_{41}H_{68}O_{17}$. The hydrolysis was completed by boiling with 5% HCl for 15 hrs. or with 5% H_2SO_4 for 60 hrs. Only glucose was proved in the hydrolyzate as the sugar constituent. Y. Kihara

Nutritional chemistry of flowers. III. Protein in the flower of wisteria, Kraunhia floribunda Taub. var. typica Mak. Sakae Sinano. *J. Agr. Chem. Soc. Japan* **15**, 723–6; *Bull. Agr. Chem. Soc. Japan* **15**, 118 (1939) (in English); cf. *C. A.* **33**, 7843⁹.—Protein in the flower was extd. with dil. NaOH and pptd. with AcOH. It was purified by repptn. The N distribution in the dry matter of protein was: total N 10.51, hot HCl-insol. N 0.78, ammonia N 0.90, humin N 0.15, arginine N 0.44, histidine N 0.82, lysine N 0.94, cystine N 0.01 and monoamino N 6.53%. The protein contained 2.85% of ash. P 0.17, Fe 0.08, and Cu 0.10% were found in the ash. During the prepn. of the protein most of it was denatured into one insol. in dil. alkali. Y. Kihara

Fractionation of soybean protein. Kinsuke Kondo, Seiiti Hayasi and Siniti Morisige. *J. Agr. Chem. Soc. Japan* **15**, 727–37 (1939).—The protein prepd. by extg. the soybean cake with dil. alkali was dissolved in 40% urea and pptd. by the addn. of alc. The ppt. was sepd. into 3 fractions. The ppt. by dil. alc. and the ppt. by concd. alc. at a definite pH were proved to be single proteins. The absorption spectrum of protein soln. seemed to have some relations to the contents of cyclic amino acids such as tyrosine and tryptophan. Y. Kihara

The effect of ethylene on the respiration and carbohydrate metabolism of potatoes. F. E. Huelin and J. Barker. *New Phytologist* **38**, 85–104 (1939).—The effect of ethylene on respiration and sugar content of potatoes at 15° was detd after varying periods of storage. Respiration increased to a max. during the first 2 days after exposure to ethylene and then fell to a level above that of the control. Increased respiration occurred with treatments of 1 p. p. m. up to 1000 p. p. m. The effect of ethylene was only slight with freshly harvested potatoes but increased with continued storage. Ethylene increased the sugar content in the later periods of storage but not in the early period. H. R. Kraybill

Formation of "fructose" units during starch hydrolysis in the later stages of the growth of the apple. Franklin Kidd and Cyril West. *New Phytologist* **38**, 123–4 (1939).—There is no extensive interconversion of "glucose" units to "fructose" units or the reverse except when starch hydrolysis is known to be occurring. Then there is an active conversion of "glucose" to "fructose." H. R. K.

Sulfur metabolism of plants. J. G. Wood and B. S. Barrien. *New Phytologist* **38**, 125–49 (1939).—The relatio as between the different S compds. of the leaves of plants receiving different supplies of K_2SO_4, NH_4Cl and cystine were studied. An increased supply of sulfate did not increase the cystine or protein S content. An increase in NH_3 increased the content of cystine and protein S as well as the amino and protein N but decreased the sulfate S content. The addn. of cystine to the sand culture increased the sulfate S but did not change the cystine or protein S contents. NH_3 acts as a limiting factor in the formation of protein S from sulfate. A scheme is proposed for the probable sequence of reactions in S metabolism. H. R. Kraybill

Early diagnosis of variation. Henri Colin and Simone Lemoyne. *Compt. rend.* **209**, 426–8 (1939).—Chem. characteristics of variation are inscribed in the grain, but the evolution of the germ of one variety or another is not known. The biochem. diagnosis of variation can only be carried out on young plants. Two varieties of *Betterave*, one used for sugar and the other for forage, were studied. There are morphological, anatomical and chem. differences between the 2. The leaves of the 2 varieties are similar chemically, but the roots show differences, although they are not apparent at first. There is more sugar, less ash, N and org. matter, more vascularization and greater foliage in the sugar variety. The phosphate reaction, Ca and Mg are always present in the sol. ash of the forage variety, while in the sugar variety, all the H_3PO_4 is in the insol. ash. Since sucrose goes into the roots more quickly in the sugar variety, there is a greater amt of ash, N and P in the roots of the forage variety. Thus the difference can be shown in the young plants. Dorothy A. Meyer

Comparison of the metabolism of mosaic-diseased potatoes with that of normal potatoes. Geo. Cockerham. *Ann. Applied Biol.* **26**, 417–39 (1939).—This is a study of the effect of virus X on the carbohydrate and total N contents of leaves from the potato varieties President and Arran Victory over various diurnal and seasonal periods. Gross carbohydrate metabolism is similar in mosaic-diseased and normal leaves. Slight modifications of fundamental metabolism have been found which are expressed as reduced photosynthetic activity, disturbed starch-sugar relationships and an impediment in translocation. These are ascribed to secondary effects arising from pathol. changes brought about by the virus infection. Transient modifications in carbohydrate metabolism have been traced to prematurely retarded growth resulting in a reduced carbohydrate demand by diseased plants. Diseased leaves contain more N at all stages of growth than normal leaves. The pathol symptoms and prematurely retarded growth activities which produce disturbances in carbohydrate metabolism are probably the direct manifestation of disorganized N metabolism. C. H. R.

The relation between production of dry matter and excretion of carbon dioxide through the roots of maize. F. Alten and R. Gottwick. *Bodenkunde u. Pflanzenernähr.* **13**, 353–70 (1939).—Soln. cultures continued for 3 months with maize seedlings in glass vessels of peculiar shape, whereby the bent stem of the plant was inserted through a Hg sealed side opening, and the soln. surrounding the roots could be aerated and the CO_2 excreted collected from the

air stream, are described. The total excretion of CO_2 from the roots averaged 10 times the cation content of the plants with a normal and about 16 times with a deficient K_2O supply. From this inverse relation, it is concluded than an abundant K_2O supply ensures high efficiency in elaboration of dry matter from the CO_2 absorbed by the leaves, other growth factors being favorable. An increased N supply without corresponding increase in K_2O increased the crop, but the efficiency of utilization of CO_2 was less, as indicated by increased excretion through the roots. Of the CO_2 assimilated by the leaves, about 89% was utilized under the most favorable conditions, but with excess N the utilization fell to 77%. The hourly excretion of CO_2 at night was 60–70% of that by day, but this was affected by the fertility level of the soln. and increased therewith to 78–79%. When the supply of nutrients to plants started in a dil. soln. was increased, the CO_2 excretion by the roots was affected consistently. Four references. C. J. Schollenberger

Responses of dormant cuttings of Lonicera tartarica to solutions of indolylacetic acid and nutrient salts. N. H. Grace and M. W. Thistle. *Can. J. Research* **17**, C, 317–20(1939); cf. following abstrs.—Cuttings of dormant *Lonicera tartarica*, collected in March, were treated with a factorial series of indolylacetic acid and nutrient solns. Indolylacetic acid was used at dosages of 0, 10, 50 and 100 p. p. m. in conjunction with 0, 1 and 10 concns. of a modified Hoagland's nutrient soln. Indolylacetic acid treatment significantly increased the percentage of rooting, and the no. and total length of roots, the fresh root wt. and the green wt. of leaf per group of cuttings treated, the higher concns. having the greater effect. The use of nutrient also significantly affected each of the foregoing characters. The results suggest that some dormant cuttings may be deficient in minerals essential for rooting, and that there is an optimum nutrient concn. somewhere below the highest used in this expt. J. W. Shipley

Responses of dormant cuttings of Lonicera tartarica to solutions of cane sugar and indolylacetic acid. N. H. Grace. *Can. J. Research* **17**, C, 334–8(1939).—Cuttings of dormant *Lonicera tartarica*, collected in March, were treated with a factorial series of indolylacetic acid and cane-sugar solns. Indolylacetic acid was used at concns. of 0, 10, 50 and 100 p. p. m., while cane sugar was present at 0, 1, 5 and 10%. Indolylacetic acid treatment greatly increased the percentage of cuttings rooted, the no. and length of roots per rooted cutting, the fresh root wt. and the green wt. of leaf produced. Cane-sugar treatment alone or in combination with indolylacetic acid failed to show any significant effects, suggesting that dormant cuttings of this plant have an adequate reserve of carbohydrate material. Apart from a somewhat greater effect of treatment on the percentage of rooting, the results are in essential agreement with those previously secured from dormant October cuttings. In comparison with a parallel expt. on the dusting of March cuttings propagated in the same frame, soln. treatment had the greater effect on all the responses considered except green wt. of leaf produced, which was greater after dusting. J. W. Shipley

Effects of cane sugar, ethyl mercuric phosphate and indolylacetic acid in talc on the rooting of cuttings. N. H. Grace. *Can. J. Research* **17**, C, 321–33(1939).—Cuttings of 2 herbaceous and 2 dormant woody plants were treated with a factorial series of talc dusts containing cane sugar, Et mercuric phosphate and indolylacetic acid. The effect of the dusts on cuttings of *Coleus blumei* and *Iresine lindeni* was detd. by the no. of roots per rooted cutting, the length of root mass and dry wt. of roots. Each of the 3 factors gave at least 1 significant effect with both plants. *Iresine lindeni* cuttings showed 2 significant interactions, one between org. Hg and indolylacetic acid on the no. of roots per rooted cutting, the other between sugar and indolylacetic acid on the length of root mass. Dormant *Lonicera tartarica* cuttings showed significant effects from indolylacetic acid on the no. of cuttings rooted, the no. and length of roots per rooted cutting, the mean root length and fresh root wts. Green leaf wts. of this plant were significantly affected by sugar, and the sugar × org. Hg, and sugar × org. Hg × indolylacetic acid interactions. Fresh root wts. also gave a significant triple interaction. The no. of *Physocarpus opulifolius* cuttings rooted was significantly increased by org. Hg as were the dry root wts. Root wts. also were affected by sugar treatment. This plant failed to make any significant responses to indolylacetic acid treatment. The results indicate that cane sugar and Et mercuric phosphate, as well as indolylacetic acid, affect some of the rooting responses of plant cuttings. It is suggested that the dust method of treating cuttings may be used to supply factors, other than the recognized growth-stimulating chemicals, that are advantageous to successful vegetative propagation of plants. J. W. Shipley

Rare earths in calcareous algae. Marcel Servigne and Arakel Tchakirian. *Compt. rend.* **209**, 570–2(1939).—Ashes of the calcareous alga, *Lithotamnion calcareum*, from Roscoff (Brittany) were extd. with HNO_3 and the resultant filtered soln. (I) contg. all the Ca and Mg, and the insol. siliceous portion (II) examd. by S.'s phosphorescent $CaWO_4$ method (cf. *C. A.* **31**, 3414[9]). This showed the presence of about 5×10^{-6} part by wt. of Pr, Nd and Sm in II, but of no rare earth in I. C. A. Silberrad

The role of magnesium in chlorosis of peach. J. Carlyle Hackney. *J. Elisha Mitchell Sci. Soc.* **54**, 191–2 (1938).—Analyses showed that leaves from chlorotic trees had a lower Mg content than those from nonchlorotic trees. Application of $MgSO_4$ or MgO increased the Mg in the leaves but not in the twigs or fruit. Trees to which no Mg was applied showed earlier defoliation than those receiving Mg. Colin W. Whittaker

PHILIP B. HAWK

The influence of diet on the endogenous production of citric acid. Arthur H. Smith and Curtis E. Meyer. *J. Biol. Chem.* **131**, 45–55(1939); cf. *C. A.* **31**, 7479[4].—Citric acid is a normal metabolite of endogenous origin and rats receiving a predominant proportion of their energy requirements from dextrin or fat excrete a much larger amt. than when protein (lactalbumin) supplies this need. With normal diets it is therefore believed that the citric acid elaborated is derived from metabolic products of fats and carbohydrates rather than of proteins. The ability of foodstuffs to give rise to citric acid appears to be independent of their acid- or base-producing role. A. P. L.

The effect of choline on the ability of homocystine to replace methionine in the diet. Vincent du Vigneaud, Joseph P. Chandler, A. W. Moyer and Dorothy M. Keppel. *J. Biol. Chem.* **131**, 57–76(1939); cf. *C. A.* **33**, 8719[6].—The administration of choline enables the rat to utilize homocystine for growth purposes instead of methionine. Choline apparently makes possible the methylation *in vivo* of homocystine to methionine. That choline is at least in part responsible for the ability of tikitiki and milk vitamin concentrate to enable the animal to utilize homocystine is shown by the actual isolation of choline from these sources. Betaine has a similar effect. A. P. Lothrop

The metabolism of carbohydrate and protein during prolonged fasting. Wm. H. Chambers, Joseph P. Chandler, S. B. Barker and James Evenden. *J. Biol. Chem.* **131**, 95–109(1939).—During prolonged fasting, as the loss in body wt. increases from 40 to 50%, dogs may exhibit either a marked rise or a very slight change in protein metabolism. The "high N" group is characterized by an approx. 3-fold increase in total N excretion, a corresponding basal R. Q. of about 0.81, about a 10-fold rise in creatinuria and a definite fall in ketone body excretion. The "low N" group maintains the low level of N excretion and high ketonuria with R. Qs. of about 0.73 and about a 5-fold increase in creatine excretion. The similarity in basal heat production and difference in length of fasting in the

2 groups suggest a greater store of body fat in the low N group. The response to a glucose meal is similar in both groups. The rise in R. Q. to about 0.89, fall in ketonuria and small excretion of sugar indicate a partial restoration of the ability to oxidize glucose. After fat ingestion the metabolism resembles that of the intermediate fasting period. Ingested fat exerts a marked N-sparing effect which is found only in the animal with depleted fat stores. Normal respiratory metabolism and specific dynamic action are observed after the ingestion of meat although the ketonuria is definitely increased. The specific dynamic action of body protein, characteristic of exptl. diabetes, is not evident in the "high N" group. A. P. Lothrop

Protein metabolism. XI. The metabolic relation of creatine and creatinine studied with isotopic nitrogen. Konrad Bloch and Rudolf Schoenheimer. *J. Biol. Chem.* **131**, P11–19(1939); cf. *C. A.* **33**, 9381[3].—Administration of small amts. of creatine contg. N^{15} is followed by an almost equal distribution of the dietary creatine N over creatine of muscle and internal organs as well as over urinary creatinine, indicating that the latter is derived mainly from the body creatine. When the body creatine of the rat is marked with isotopic N during a preliminary period and then creatine is omitted from the diet in the following period, the isotope content of the urinary creatinine is identical with that of the body creatine. This is a clear indication that body creatine is the only precursor of urinary creatinine on a creatine-free diet. The reaction creatine ⇄ creatinine is biologically irreversible since no isotopic N is found in the body creatine after administration of creatinine contg. N^{15}. There is immediate excretion of most of the isotopic creatinine in the urine. The isotopic creatine was prepd. from isotopic glycine as a starting material. It was shown that the N in creatine is stable and does not exchange *in vitro* with the N of NH_3. A. P. Lothrop

Inhibition of growth of the rat by oral administration of methylcholanthrene, benzopyrene or pyrene and the effects of various dietary supplements. Julius White and Abraham White. *J. Biol. Chem.* **131**, 149–61(1939); cf. *C. A.* **33**, 7385[6].—The inhibition of the growth of the rat by certain org. compds. is a manifestation of the production of a specific deficiency in the S-contg. amino acids, probably by imposing on the organism an increased requirement for org. S, in the form of methionine or cystine, for detoxication purposes. The growth retardation produced by feeding either methylcholanthrene, benzopyrene or pyrene was promptly relieved by dietary supplements of *l*-cystine, *dl*-methionine or *l*-cystine disulfoxide Taurine, Na_2SO_4 and glycine were ineffective. Injection of glutathione also produced an increase in growth rate in animals ingesting the methylcholanthrene-contg. diet. There is as yet no clear indication that the carcinogenic properties of a compd. have any relation to the amt. of this material which will inhibit growth of young rats under the exptl conditions employed. The quantity of a compd. required to produce growth retardation must be detd. by trial and error and appears to be related to the toxicity of the substance. A. P. Lothrop

The availability for growth of *N*-methyltryptophan administered as its acetyl derivative. Wm. G. Gordon, Wm. M. Cahill and Richard W. Jackson. *J. Biol. Chem.* **131**, 189–96(1939); cf. *C. A.* **33**, 7355[2].—Acetyl-*l*-*N*-methyltryptophan is not utilized for growth in the rat ingesting a diet deficient in tryptophan. Inasmuch as both *l*-*N*-methyltryptophan and acetyl-*l*-tryptophan both promote growth, the substitution of the Me group for the amide H of the latter compd. apparently prevents its hydrolytic cleavage in the body. A. P. Lothrop

Vitamin C studies in the rat. The effect of copper and various organic substances. Joseph L. Svirbely. *J. Biol. Chem.* **131**, 233–41(1939); cf. *C. A.* **30**, 6427[6].—Significant amts. of vitamin C were found in all the organs of the rat regardless of the diet fed or the substance administered. Injections of pyridine, camphor, menthol, borneol, thymol and phenylacetic acid to fasting rats or of amidopyrine and antipyrine to animals on a dog chow diet showed high reducing capacities of the liver and gut. Toluenediamine caused a decrease in the liver and gut while phlorizin showed higher values for the gut than for the liver. A marked decrease in the vitamin C content of the adrenals followed feeding of acetanilide, acetophenetidin and, to a smaller extent, amidopyrine and the injection of camphor, borneol, toluenediamine and hydrazine. The concn. of vitamin C per g. of tissue, ordinarily based on the actual wts. of the organs, should be corrected for the variation in wt. of the liver and gut which may result from the administration of foreign substances. This correction can be based on observations on the control animals and the relative wts. of the organs per 100 g. unit of final body wt. A. P. Lothrop

The inversion of *d*-phenylaminobutyric acid and the acetylation of *l*-phenylaminobutyric acid by means of the isotopes of nitrogen and hydrogen. Vincent du Vigneaud, Mildred Cohn, Geo. B. Brown, Oliver J. Irish, Rudolf Schoenheimer and D. Rittenberg. *J. Biol. Chem.* **131**, 273–96(1939); cf. *C. A.* **32**, 1764[1].—In the inversion *in vivo* of *d*-phenylaminobutyric acid contg. N^{15} and conversion to the acetyl-*l*-phenylaminobutyric acid, almost all of the original N of the compd. fed is replaced by new N By feeding the compd. to animals whose D content of the body fluids was raised to approx. 2.5 atom %, it was possible to show that 1 atom of D was taken up in the α position of the amino acid moiety of the excreted compd. during the process. These exptl. facts agree with the hypothesis that the keto acid is an intermediate in the inversion of an unnatural isomer to its enantiomorph. The acetyl-*l*-phenylaminobutyric acid excreted after the feeding of *l*-phenylaminobutyric acid contained a large proportion of the original N in contrast with the *d* isomer. In expts. in which the animals were given D_2O, it was again found that the acetyl-*l*-phenylaminobutyric acid contained 1 atom of D in the α position as in the expt. in which the *d* acid was fed. The various mechanisms that might explain these exptl. observations are discussed in detail. The phenylaminobutyric acid contg. N^{15} was prepd. by catalytic reduction of cinnamoylformic acid with isotopic NH_3. A new resolution of *dl*-phenylaminobutyric acid is described in which the phenylethylamine salt of the carbobenzoxy deriv. is utilized. A. P. Lothrop

Comparison of vitamins A and A_2 by distillation. E. LeB. Gray. *J. Biol. Chem.* **131**, 317–26(1939).—The temp. of the elimination max. of vitamin A_2 is only 3° above that of vitamin A, indicating that the mols. of the 2 vitamins contain the same no. of C atoms. Cf. *C. A.* **32**, 6694[6]. A. P. Lothrop

Vitamin K activity in the benzoquinone series. S. Ansbache and Erhard Fernholz. *J. Biol. Chem.* **131**, 399–400(1939); cf. *C. A.* **33**, 6922[9].—Phlorone (2,5-dimethylbenzoquinone) is apparently the simplest compd. with vitamin K activity investigated to date. Although it is approx. 2000 times less active than 2-methyl-1,4-naphthoquinone, the speed of action and period of efficiency are practically identical for the 2 compds., unit for unit. Cf. Almquist and Klose, *C. A.* **33**, 9382[1]. A. P. L.

Deriv. of vitamin K_1 (Almquist, Klose) **10**.

HOMER W. SMITH

Further contributions to the study of the chemical activity of the nerves. Quinto Calabro. *Ricerca sci.* **10**, 427–31(1939); cf. *C. A.* **31**, 7954[9].—A discussion of the effects of insulin (I), acetylcholine (II), cardiazole (III) and atropine (IV) on the nervous system. In the rabbit intravenous injection of 50 international units of I followed by removal of the nerve trunk and immersion in eosinated Ringer soln. ($1:6 \times 10^6$) caused activity of the vagus nerve so that it was used to contract a leech prepn. and inhibited the action of a heart prepn. (Bufo). The sciatic nerve similarly prepd. had no action on the leech but activated the heart prepn. Controls showed no activity. One end of the left vagus nerve of a rabbit injected with 0.02 g. of II chloride was immersed in Ringer soln. as above and the right peripheral vagus stump of a second

rabbit was immersed in the same soln. The carotid pressure decreased in 9 cases, was not affected in 13 and was raised in 2 cases. In the cases of diminished pressure, removal of the nerve stump of the second rabbit from the Ringer soln. resulted in a marked increase in pressure, but dipping it into a soln. of II in the Ringer soln. had no effect. The conclusion is drawn that a vagus substance is liberated in the soln. which transmits the effect to the second rabbit. III likewise is able to liberate a substance from nerves if used in convulsion-producing doses. A nerve block often fails to stop the action of IV, manifested finally at the vagal inversion. These observations can be interpreted by assuming the formation of an active substance by the nerves. W. F. Bruce

Endocrine compounds. The pituitary gland. A. Richard Bliss, Jr. *Drug Cosmetic Ind.* **45**, 426–8(1939); cf. *C. A.* **33**, 8736[7].—The prepn. and action of the following principles of this gland are reviewed: thyrotropic, adrenotropic, diabetogenic, ketogenic, blood-sugar raising and parathyrotropic. H. M. Burlage

Phagocytic activity of the leucocytes of preserved placental and retroplacental blood. A. G. Karavanov and N. C. Baksheev. *Méd. exptl.* (Ukraine) 1939, No. 2, 36–40.—Phagocytic activity of the blood (preserved with citrate) was somewhat decreased during the first day after collection (cause unknown) but increased again on the second day, began to decline once more on the third day, and disappeared altogether 5–6 days after collection. The monocytes retained their phagocytic activity for longer periods than the other cells. Retroplacental blood lost its phagocytic activity earlier than placental blood. S. A. Corson

Metabolism of normal preschool children. III. Variations in nitrogen storage on constant diets. Thelma Porter. *J. Am. Dietet. Assoc.* **15**, 427–34(1939).—Forty-three N balances of 3 children $2^1/_2$, $4^2/_3$ and $5^1/_2$ yrs. old are reported. A total of 41 3-day balances were secured. Protein consumption varied from 2.12 g./kg. body wt. for the oldest to 2.68 g./kg. for the youngest child. Protein furnished about 12% of the total cal. The N storage averaged 1.26, 1.14 and 1.30 g./day from the oldest through the youngest child. E. Curzon

Adsorption studies on enamel, dentine and bone. Marian LeFevre Manly and Sylvia R. Levy. *J. Am. Chem. Soc.* **61**, 2588–90(1939).—Quant. measurements on the adsorption of phosphate ion by powd. enamel, dentine and bone indicate that the adsorption power of dentine and bone is about the same and is 7 times greater than that of enamel. These data satisfy exactly the criteria for adsorption according to Freundlich's adsorption isotherm. A. B. Garrett

Variations in plasma potassium in states of hypotension and hypertension. Jorge L. Moglia. *Anales farm. bioquím.* (Buenos Aires) **10**, 26–63(1939); cf. *C. A.* **33**, 8741[8].—In dogs a drop in blood pressure produced by any means (shock, nerve section, drugs, bleeding) causes an increase in plasma K. When the pressure returns to normal the K also returns to normal or nearly so. L. E. Gilson

Biometric study of testicular growth provoked by the injection of serum gonadotropin in hypophysectomized rats. S. Gothié and R. Moricard. *Compt. rend. soc. biol.* **131**, 1212–13(1939).—Graphs. L. E. G.

Hormonal stimulation of meiosis by injection of gonadotropins from serum and anterior hypophysis. R. Moricard and S. Gothié. *Compt. rend. soc. biol.* **131**, 1214–16(1939).—In hypophysectomized rats injections of anterior hypophysis gonadotropin reëstablished normal spermatogenesis. Serum gonadotropin stimulated proliferation of interstitial cells but did not promote spermatogenesis. L. E. Gilson

Oxygen consumption and carbon dioxide production of unanesthetized kidneys grafted on the neck vessels. M. Dor. *Compt. rend. soc. biol.* **131**, 1272–3(1939); cf. *C. A.* **33**, 5047[9].—The results are practically the same as previously reported for dogs anesthetized with chloralosane. **Functional and metabolic recovery of unanesthetized grafted kidneys after prolonged arrest of circulation.** *Ibid.* 1273–4.—The kidneys recovered in a few min. after circulation had been arrested 20–40 min. After 60 min. circulatory arrest recovery was less than 25% complete an hr. after circulation was reëstablished. L. E. G.

Reversible suppression of the effects of excitation of the vagus by active substances of heart [nodal tissue]. R. Cabrera-Malo. *Compt. rend. soc. biol.* **131**, 1284–7(1939).—Perfusion of the frog heart *in situ* with Ringer soln. contg. the active substances of mammalian heart nodal tissue temporarily suppresses the effect of excitation of the right and left vagi. The nodal ext. also antagonizes the action of acetylcholine. L. E. Gilson

Influence of progestin on the gonadotropic function of the hypophysis of the rat. Marc Herlant. *Compt. rend. soc. biol.* **131**, 1315–17(1939).—The effects were irregular and of uncertain significance. **Effects of progestin on the histological structure of the rat hypophysis.** *Ibid.* 1318–21. L. E. Gilson

Identity of an antibacterial factor in the saliva of certain mammalia. S. Leonard Rosenthal, Wallace M. McNabb and Raymond C. Snyder. *J. Am. Dental Assoc.* **26**, 1859–62(1939).—Saliva of normal animals (dog, cat, monkey, horse, rhinoceros) contained a compd. which inhibited the motile oral flora of man, but had little effect on the nonmotile bacteria. Examn. of dog saliva showed this compd. to be Na_2CO_3, which was absent from human saliva; its disappearance from the saliva of normal animals rendered them liable to fusospirochetal infection. Solns. of Na_2CO_3 were of value in the treatment of Vincent's infection. Joseph S. Hepburn

Is muscle contraction an atom-dynamical or a kinetic-statistical process? Edgar Wöhlisch. *Naturwissenschaften* **27**, 678–9(1939).—A theory of muscular contraction based upon the idea of internal pressure. B. J. C. van der Hoeven

The carotenoid nature of yellow pigment in the chicken iris. W. F. Hollander and R. D. Owen. *Poultry Sci.* **18**, 383–7(1939).—The yellow pigment of the chicken iris is composed of carotene and xanthophyll. Carotenoids are not present in the iris of the pigeon. K. D. J.

Regulatory changes in blood chemistry and metabolism under reduced pressure. G. E. Vladimirov, *J. Physiol. U. S. S. R.* **25**, 779–85(in German, 784–5)(1938).—At altitudes of 1250–5590 m. the total electrolyte content of plasma is unchanged. An increase in K^+ and a corresponding decrease in Na^+ are observed. The carbonate content decreases as a result of the decrease in the partial pressure of CO_2 in the lungs and the accumulation of org. acids in the blood. During the 1st few days at high altitudes the blood pH increases. A longer stay, or particularly climbing to still higher altitudes, results in a fall in pH to normal or subnormal levels. Blood lactic acid and excreted ketonic bodies in the urine are increased while Me_2CO, acetoacetic acid and β-hydroxybutyric acid (I) appear in the blood stream as a result of anoxemia. A direct study of the effect of acute anoxemia in guinea pigs showed that the increase in ketonic bodies is a result of disturbance of kidney function. A short period of anoxemia caused an increase in free Me_2CO and I in the liver. S. A. Karjala

The possibility of cortical regulation of the permeability of glandular tissue. M. Ya. Mikhel'son. *J. Physiol. U. S. S. R.* **25**, 857–64(in English, 864)(1938).—The excretion of KI in saliva adjusts itself at a steady level 1–2 hrs. after KI injection provided normal unconditioned salivary secretion is maintained by periodic feeding of meat-biscuit powder or the injection of pilocarpine. The tissue permeability of the salivary glands is altered by impulses originating in the cerebral cortex as a result of food-conditioned stimuli, excitatory impulses decreasing and inhibitory impulses increasing permeability. S. A. Karjala

The influence of the cerebral cortex on the elimination of iodine by the salivary gland upon extinction of the conditioned reflex. V. N. Chernigovskiĭ. *J. Physiol. U. S. S. R.* **25**, 865–70(in French, 870)(1938).—Dogs were given food contg. 0.4–0.6 g. of KI and were injected 2 hrs. later with 8–10 mg. of pilocarpine with the simul-

taneous application of a pos. stimulus (ringing of a bell for 8 sec. at 2-min. intervals 10–16 times). The KI in the saliva collected at 4-min. intervals was detd. During the 1st few min., when the bell served as an excitatory stimulus, the KI in the saliva diminished. A gradual increase in KI excretion indicated a slow but complete extinction of the conditioned reflex. S. A. Karjala

Humoral regulation of gastric and intestinal motility. I. Kurtsin and A. Rogov. *J. Physiol. U. S. S. R.* 25, 877–84 (in English, 884) (1938).—The perfusate obtained from the brain of a surviving fish head during prolonged stimulation of the vagus nerve by induction shocks caused energetic contractions of the pyloric part of the stomach and of the intestine of cats. Perfusates obtained from fish brain during stimulation of the afferent nerves (trigeminus and olfactory) caused inhibition of gastric and intestinal peristalsis. Thus excitation of the central nervous system results in the formation of specific substances or mediators capable of exerting a humoral control over the motor activity of the digestive app.

S. A. Karjala

Fluctuations in the amylolytic index of blood and urine as a result of the periodic activity of the digestive apparatus aside from digestion. G. P. Mushegyan. *J. Physiol. U. S. S. R.* 26, 291-5 (in German, 295) (1939).—The function of the kidney during the course of periodic activity aside from digestion was studied in dogs with intestinal fistulas. At the beginning of a rest period the amylolytic index (I) of the urine is at a max. At the middle of a rest period I begins to fall and reaches a min. at the end of the period. During the time of periodic activity I in the urine remains at a low level or disappears entirely, while in the blood it rises to a max., begins to decrease during the rest period and reaches a min. at the end of the rest period. Acid contractions of the stomach have no effect on the fluctuation of I. I is also independent of fluctuations in the creatinine content of the urine. S. A. Karjala

Vitamin A and carotene in the hen egg during hatching. Paavo Suomalainen. *Suomen Kemistilehti* 12B, 30 (1939) (in English).—The vitamin A (I) content of incubated eggs decreases by 45% during the 2nd and 3rd weeks of incubation, but the carotene (II) content does not decrease during hatching. The developing embryo used 350 I. U. of I during the last 2 incubation weeks, or approx. 25 I. U./day. The 1-week-old embryo contained 0.4%, and the 2-week-old embryo 6.3%, of the total I of the egg. The liver of the newly hatched chick contained 10 I. U. (8.1%) of the total II, and 95 I. U. (21.6%) of the total I of the chick. S. A. Karjala

Composition of the gastric mucous membrane. Heinrich Fuchs. *Z. Biol.* 99, 484–7 (1939).—Gravimetric analysis showed arginine, lysine, tyrosine and leucine occurred free in the gastric mucous membrane of pigs, while histidine was identified qualitatively only. Nicotinic acid and nicotinic acid amide were also found, explaining the beneficial influence of gastric mucous membrane on pellagra. Histamine was detected by Edlbacher's method. Frances Krasnow

Inhibition of lactic acid formation with oxygen. Amandus Hahn, G. Niemer and W. Gasseling. *Z. Biol.* 99, 614–17 (1939).—Oxygen inhibition was restored by addn. of a thermostable substance which had been previously washed out of the muscle pulp. Apparently this is not identical with succinic, fumaric, malic or oxalacetic acids. Frances Krasnow

Acetylcholine and choline esterase in degenerating nerves. Horst Hellauer and Karl Umrath. *Z. Biol.* 99, 624–32 (1939); cf. *C. A.* 33, 9397[8].—Cutting the motor nerves increased the acetylcholine content as long as there was transfer of excitation to the muscle, but the choline esterase remained unaltered. When transfer of excitation to muscle was blocked but nerve action currents still liberated, acetylcholine and choline esterase decreased to a slight end value. (In amphibians the acetylcholine increased when conduction was first blocked.) The action currents liberated in sensory nerves by muscle tension disappeared late in *Rana esculenta* and early in *Rana temporaria*. Frances Krasnow

The possible carrier role of ascorbic acid in animal tissues. M. O. Schultze, Carter J. Harrer and C. G. King. *J. Biol. Chem.* 131, 5–12 (1939); cf. *C. A.* 32, 1770[1].—Ascorbic acid is not a catalytically active, oxidation-reduction carrier in animal tissue. It does not function as a H-transfer agent in a system contg. nicotine hemochromogen, ascorbic acid, coenzyme, glucose dehydrogenase and glucose. The presence of glutathione, either in place of or with ascorbic acid, does not alter the H-transfer results although both reagents are oxidized aerobically in the presence of hemochromogen. Until more conclusive evidence is obtained the concept that ascorbic acid functions in animal tissues as a respiratory carrier remains essentially unsupported by exptl. evidence.

A. P. Lothrop

Electrodialysis of tissue chloride. II. Kinetics of removal of chloride from tissues of the dog. Robert H. Oster and Wm. R. Amberson. *J. Biol. Chem.* 131, 19–24 (1939); cf. *C. A.* 34, 125[2].—The rate at which chloride can be electrodialyzed from brain, stomach, spleen, pancreas and possibly lung tissue is significantly lower than for skeletal muscle, indicating that in these tissues a significant part of the chloride is intracellular while in muscle the chloride is assocd. with the extracellular phase of this tissue. An average of about 5.5% of the total chloride of brain remains in the tissue after long electrodialysis and it is suggested that part of the intracellular chloride may be organically bound. A. P. Lothrop

The effect of a nicotinic acid deficiency upon the coenzyme I content of animal tissues. A. E. Axelrod, Robert J. Madden and C. A. Elvehjem. *J. Biol. Chem.* 131, 85–93 (1939); cf. *C. A.* 33, 4650[9].—There is a significant decrease in the coenzyme I content of liver and muscle tissue in uncomplicated nicotinic acid deficiency in the dog and in the pig. The brain, kidney cortex and blood, however, always maintained their normal coenzyme I content, indicating that a normal level of the enzyme is absolutely essential for life of these tissues. It is not possible to increase the coenzyme I content of rat tissue by the administration of excessive amts. of nicotinic acid.

A. P. Lothrop

The utilization of acetone bodies. II. The influence of sex. Isabelle Grayman, Norton Nelson and I. Arthur Mirsky. *J. Biol. Chem.* 131, 121–6 (1939); cf. *C. A.* 33, 8749[3].—The disappearance of intravenously administered β-hydroxybutyrate from the whole bodies of fed rats, both nephrectomized and normal, were studied to obviate the effects of absorption, diffusion, variable rates of excretion and spontaneous acetone body formation. No significant differences in the rates of utilization were observed in male and female rats. The sex difference reported by others was probably due to variations in endogenous ketone formation. A. P. Lothrop

Metabolism of certain rare sugars. Florence Clarke, Roy Solkot and Ralph C. Corley. *J. Biol. Chem.* 131, 135–8 (1939).—Intestinal administration of melezitose, turanose and trehalose results in an increase in the glycogen of the liver of fasting white rats. Neg. results with raffinose and melibiose indicate the absence of a β-fructosidase and of an α-galactosidase in the alimentary tract of the rat. The pos. results with trehalose indicate the presence of trehalase, an α-glucosidase differing perhaps from maltase, and with the other 2 sugars the presence of an α-glucosidase possibly identical with maltase.

A. P. Lothrop

Nature of the increase in activity of the *d*-amino acid oxidase of rat liver produced by thyroid feeding. J. R. Klein. *J. Biol. Chem.* 131, 139–47 (1939); cf. *C. A.* 33, 5051[4].—The increase in activity of the *d*-amino acid oxidase of rat liver produced by thyroid feeding is not dependent upon a change in the nature of the flavin component nor upon the components of liver sol. in ½ satd. $(NH_4)_2SO_4$ but, is probably due to an increase in the concn. of the protein component of the oxidase. The concn. of the flavin component is not increased by the thyroid feeding. A. P. Lothrop

Action of ketene on gonadotropic hormones. Choh Hao Li, Miriam E. Simpson and Herbert M. Evans. *J. Biol. Chem.* 131, 259–66(1939); cf. *C. A.* 33, 8269⁸.—Ketene reacts rapidly with NH_2, and more slowly with phenolic OH groups in aq. solns. of protein and has been used in acetylating gonadotropically active proteins. The results indicate that the physiol. activity of the pituitary follicle-stimulating and interstitial cell-stimulating hormones and of the gonadotropic hormone in pregnant mare serum is in each case dependent on the free NH_2 groups. On the other hand, the gonadotropic principle found in the urine of pregnant women (human chorionic gonadotropin) resembles insulin and pepsin in that the phenolic OH rather than the free NH_2 groups are essential for the biol. activity. A. P. Lothrop 1 2

Effect of age and fasting on glycogen content of liver and muscle of rats and puppies. Walter Heymann and J. L. Modic. *J. Biol. Chem.* 131, 297–308(1939); cf. *J. Pediat.* 12, 21(1938).—Rats of 3 age groups, 8–11 days, 10–12 weeks and 2–3 yrs., were studied. In rats 8–11 days old the liver glycogen content is 1/3 that for animals in the older groups. The glycogen content of the livers of 6 day-old puppies is also low. This value increases steadily during the 1st 6 weeks, the av. value at 6 weeks being 5.5 g. per 100 g. of fresh liver, a value only slightly higher than the av. (4.6 g.) for full-grown animals. The increase in liver glycogen in baby rats takes place mainly during the nursing period, indicating that the causes for the low content and its rise during infancy are endogenous in nature. The muscle glycogen content is approx. the same at all ages and diminishes after 1 and 2 days fasting in all age groups with the same ease, a finding not supporting the hypothesis that the liver retains its glycogen deposit with greater tenacity during infancy. No hypoglucemia develops after a 2-day fast, a result differing from that observed in human infants and children. The livers of baby rats have the highest H_2O content in spite of having the lowest glycogen content. The diminution in liver glycogen produced by fasting is not accompanied by a corresponding loss in liver H_2O so that the important role which glycogen is supposed to play as a water binder is not evident from these results. The low content of glycogen does not make the liver more vulnerable to CCl_4 poisoning since baby rats tolerate it better than older rats. A. P. Lothrop 3 4 5 6

The influence of folliculin on the energy metabolism of woman. Virginio Piacentini and Francesco Guercio. *Arch. sci. biol.* (Italy) 24, 239–48(1938).—The basal metabolism of control women and those who received 50,000–250,000 units of folliculin did not vary appreciably. Neither was there any change in the R. Q. P. F. Metildi 7

Oxidation of butyric acid and some of its derivatives on the part of isolated sections of the kidney. E. Ciaranfi. *Arch. sci. biol.* (Italy) 24, 319–31(1938).—Butyric acid undergoes a β- and probably also an ω-oxidation in the kidney; the latter occurs only when the carboxyl group is blocked by esterification. This process that transforms butyric acid to succinic, pyruvic and lactic acids, constitutes a stage between fat and carbohydrate metabolism. Free butyric acid probably undergoes only β-oxidation. The process seems purely dehydrogenative; this excludes the possibility that its mol. undergoes a profound demolition in the kidney. The first products of oxidation (crotonic, β-hydroxybutyric and acetoacetic acids) are found only in minute quantities, since they are eventually destroyed. P. F. Metildi

The intestinal absorption of ouabain. C. Lenti. *Arch. sci. biol.* (Italy) 24, 405–10(1938).—In the small intestine ouabain is absorbed slowly. Phlorizin does not change the speed of absorption and monoiodoacetic acid slows it down slightly. The absorption is independent of the formation of phosphoric esters. P. F. M. 8 9

The actual blood reaction of thyro- and para-thyroidectomized animals. A. De Niederhäusern and C. Sisto. *Arch. sci. biol.* (Italy) 24, 471–85(1938).—Thyroidectomy in dogs modifies the physicochem. equil. and shifts it toward acidosis while parathyroidectomy alone or associated with thyroidectomy produces a tendency toward alkalosis. The tetanic manifestations may be due to the alkalosis. P. F. Metildi 1

Protein storage in the liver. F. Av de Moura Campos. *Arch. sci. biol.* (Italy) 24, 500–2(1938).—When the quantity of protein ingested is above the need of the animal for growth, protein is stored in the liver. P. F. Metildi

Chemical state of iron in fertilized hen egg and in the embryo during development. C. Lenti. *Arch. sci. biol.* (Italy) 25, 1–6(1939).—In the yolk Fe is all in the ionic form: in the white it is firmly bound to protein. The formation of Fe-org. compds. in the embryo follows an exponential law. P. F. Metildi 2

The diaphragm muscle and its kinesthesic components. A. Cardin. *Arch. sci. biol.* (Italy) 25, 51–88(1939).—Some problems concerning the motility and sensibility of the diaphragm, the process of phrenic nerve regeneration and the functional modifications were examd. after unilateral and bilateral phrenectomy. P. F. Metildi 3

The significance of the difference in concentration between the white and yolk of hen eggs. V. Capraro and P. Fornaroli. *Arch. sci. biol.* (Italy) 25, 119–25(1939).—The potential between egg white and yolk never exceeds 2–3 mv. instead of about 130 mv. which would be the case if the difference in pH were caused by the Donnan equil. Therefore, the difference in pH in particular and in concn. in general which exists between the yolk and white is the result of a resistance opposed by the egg substances to the passage of diffusible products. This is confirmed by the fact that the coeff. of diffusion of lactic acid into the yolk has been found to be very small. P. F. Metildi 4

Hyperglucemia from bleeding after thyro- and parathyroidectomy. A. Aggazzotti. *Arch. sci. biol.* (Italy) 25, 126–35(1939).—Hyperglucemia after bleeding is inhibited or destroyed in thyro- and parathyroidectomized dogs. A. thinks that these 2 glands act as reënforcers for the cortex. P. F. Metildi 5

Regeneration of the testis in fowls treated with testicular hormone. M. Laporta and P. Miletto. *Arch. sci. biol.* (Italy) 25, 169–77(1939).—Fowls, having minute testicular fragments by incomplete castration, when treated with testosterone propionate may show increased endocrine activity of the regenerated tissue. P. F. M. 6

The chemical composition and physicochemical properties of the seminal fluid. V. Zagami. *Arch. sci. biol.* (Italy) 25, 208–53(1939); cf. *C. A.* 33, 7358⁸.—The following values were obtained at 20°:

	Man	Dog	Rabbit	Cock
Density	1.028	1.011–1.012		
Lowering of f. p.	0.56°–0.58°	0.58°–0.60°		
Specific elec. cond.	88–107 × 10^{-4} mhos	129–138 × 10^{-4}		
pH	7.35–7.50	6.67–6.76	6.59–6.86	7.02–7.18
Relative viscosity	6.45	1.14–1.17		
Surface tension in dynes-cm.	66	64–67		

For a temp. rise from 20° to 38° the seminal fluids of man and dog show an av. decrease in pH of 0.27 and 0.24, resp. The human seminal fluid can be dild. in the ratio of 1:10 without pH variations greater than 0.04. The specific elec. cond. of the seminal fluid of man and dog rises on an av. of 2.51 and 2.31%, resp., for each degree rise in temp. as compared to the cond. at 18°. P. F. Metildi

The metabolism of lactic acid in hen eggs during development. V. Capraro and P. Fornaroli. *Arch. sci. biol.* (Italy) 25, 279–91(1939).—In fertilized eggs incubated at 37–39° and normally developed, the lactic acid concn. in the yolk rises rapidly in the first week up to 205 mg. % and then decreases to the initial value within the 10th–12th day. In the white there is an increase to 50 mg. % in the first 3 days and then a decrease to the initial value on the 5th day. Afterward they are unchanged. In the unfertilized eggs only slight changes were noted. P. F. Metildi

Permeability of the vitellin membrane of the yolk of hen eggs to water and the factors that modify it. Antonietta Orru. *Arch. sci. biol.* (Italy) 25, 292–308(1939).—The permeability of the vitellin membrane to water is diminished by several electrolytes. The greatest effect was produced by salts of bivalent metals. P. F. M.

The chlorine content in symmetrical organs of the rat. A. Salvatori. *Biochim. terap. sper.* 26, 344–5(1939).—The Cl content is identical in symmetrical organs. A. E. Meyer

Physicochemical changes produced in the serum by successive bleedings of the same horse. D. Brocq-Rousseu A. Boutaric and Madelaine Roy. *Bull. acad. méd.* 121, 158–66(1939); cf. *C. A.* 33, 5466⁸.—Viscosity and optical activity, both depending on the protein content, show a rapid decrease during the first 5 bleedings. Thereafter a relative equil. is obtained, with fluctuation, but a trend toward further decrease. A. E. Meyer

Latent carbon monoxide in the blood. Maurice Loeper. *Bull. acad. méd.* 121, 444–50(1939).—Nicloux's method (cf. *C. A.* 24, 5254) permits the detn. of CO in 1 cc. of blood; 1 to 1.5 cc. per l. is normal, values over 2 cc. are pathol. High CO values are found in a variety of diseases, showing endogenous intoxication. It originates from incomplete oxidation of carbohydrates, particularly also of $C_3O_4H_2$. The treatment consists in aeration, altitude and application of methylene blue. A. E. M.

The influence of hepatic catalase on the blood sugar. Henri Werner. *Sang* 13, 348(1939).—The intravenous injection of hepatic catalase results in a reduction of a blood sugar which is attributed to some effect on the oxidation-reduction system. I. Arthur Mirsky

Photoelectric study of blood plasma. Noel Fiessinger and Michel Albeaux-Fernet. *Sang* 13, 456(1939).—When photoelec. cells were used for the examn. of Bengal Rose in blood plasma, difficulty was experienced with the choice of filters, the variations in CO_2 content of plasma, and with variations in known standard solns. of plasma and Bengal-Rose, which seems to prevent the use of electrophotometry for the above problem. I. Arthur Mirsky

Clinical value of determination of coagulability of blood by coaguloretractovisometry during pregnancy and in the course of gynecologic disorders. L. Blacher. *Sang* 13, 624(1939).—By use of a coaguloretractovisometry, it was found that during the final weeks of pregnancy the coagulability of blood is normal. During early pregnancy complicated by vomiting, it is not normal. All reactions of the coagulability of blood are abnormal in extrauterine pregnancy. Variations also occur during the menopause and in various types of gynecological conditions. I. Arthur Mirsky

Bibliography of the German hematological literature for 1938. Hans Schulter and Horst Kuhl. *Folia Haematol.* 63, 100–23(1939); cf. *C. A.* 32, 8532⁸.—About 400 references. John T. Myers

French hematological literature for 1938. Edouard Jequier. *Folia Haematol.* 63, 124–43(1939); cf. *C. A.* 32, 8532⁷.—52 references with brief abstracts. J. T. M.

Some effects of the administration of estrogens on the organs of castrated and noncastrated male rats partially deprived of vitamin A. E. M. Hume, R. Burbank and V. Korenchevsky. *J. Path. Bact.* 49, 291–8(1939).—Moderate doses of estrogen were given to 33 castrated and 23 noncastrated rats which had been subjected to long deprivation of vitamin A. In noncastrated rats, the earliest effect was a decrease in wt. and size of the seminal vesicles, prostate and coagulating glands with a decreased amt. of secretion in the glandular tubules. There was marked stratification of epithelium, squamous metaplasia, keratinization, and papillomatosis of the secondary sex organs and bladder in both castrated and noncastrated rats. In castrated rats there was also fibrous and muscular hypertrophy in the seminal vesicles and prostate. These changes were always more severe if the animals were deprived of vitamin A, and given estrogen at the same time. Severe degeneration of the testes and the formation of bladder calculi were specific for lack of vitamin A. Hypertrophy of fibrous tissue and muscle is specific for the administration of estrogens. John T. Myers

Formation of phenols. D. Yanagihara. *J. Chosen Med. Assoc.* 29, 367–80(German abstr. 21)(1939).—Aligation of the duodenum of rabbits raises the PhOH content (A) of the blood, but that of the small intestine and the lower portion of the colon produces practically no effect, urinary PhOH (B) decreasing in both cases. During starvation, A does not increase until nonprotein N of the blood begins to increase as autolysis sets in, but B declines from the very beginning. A similar increase in PhOH by autolysis is observed in liver, kidney, lung, muscle and brain. The intestinal putrefaction is not the only source of PhOH formation. S. Tashiro

Blood picture of the healthy Koreans. Y. K. Lee and H. K Lee. *J. Chosen Med. Assoc.* 29, 386–91(English abstr. 23–5)(1939).—The analysis of blood of 58 healthy males of 16–52 years old (78% being between 16 and 25), and 43 females of 16–41 years old (88% being 16–25 years) shows that the Koreans have a greater hemoglobin content (99.24% for male, 87.66% for female), a slightly higher eosinophile and lower blood platelets. S. Tashiro

Control of blood indican by nephrohormone. Yositura Atumi. *J. Chosen Med. Assoc.* 29, 514–29(English abstr. 34–5)(1939).—When 1 cc. per kg. body wt. of 1% U nitrate soln. is injected into rabbits, indicanemia occurs in 4–5 days. If the serum of renal arterial blood of a normal rabbit is injected into such an animal, the blood indican gradually increases, but that of renal venous blood decreases, and urinary indican increases. The kidney forms a substance which is secreted in the blood, and lowers pathol. indicanemia, and increases urinary secretion of indican. This substance is a sterol complex, and is produced in tubules, as damage to the glomeruli does not diminish this substance. S. Tashiro

Control of diuresis by nephrohormone. Yositura Atumi. *J. Chosen Med. Assoc.* 29, 669–86(English abstr. 41–2)(1939).—The same nephrohormone has the power to control diuresis. S. Tashiro

The influence of nephrohormone on indican synthesis from indole, and resistance against indole poisoning. Ziro Masuda. *J. Chosen Med. Assoc.* 29, 581–93(German abstr. 37–8)(1939).—Renal venous blood contains a substance which has the power to convert indole to indican. This substance has the power to increase the animal's resistance against indole. It is produced in tubules and is identical with nephrohormone (Tokumitsu). S. Tashiro

Quantitative relationship between stability of erythrocytes and ionic concentration in the aqueous solution of organic salts. Sunao Togo. *J. Chosen Med. Assoc.* 29, 941–61(French abstr. 58–9)(1939).—The detn. of the stability of both nucleated (fowl) and nonnucleated erythrocytes (cattle) in aq. solns. of Na formates, tartrate and citrate shows that the stability is proportional to the theoretical ionic concn. of the salts, not to the actual ionic concn. as detd. from elec. cond., f. p. or from Debye-Hückel effect. S. Tashiro

Significance of ionic concentration in the viscosity change of erythrocyte suspensions in neutral inorganic salt solutions. Syakken Kin. *J. Chosen Med. Assoc.* 29, 962–83(French abstr. 59–61)(1939).—The high concns. of neutral inorg. salt solns. cause a gelatination of nucleated erythrocytes suspension (fowl) and that of nonnucleated erythrocytes (cattle) to a lesser degree. The viscosity of nonnucleated erythrocytes suspension shows a marked increase at the min. hemolytic concn. of the salts, while that of the nucleated a marked decrease. The salt concns. are more significant when expressed by their actual ionic concn. rather than the theoretical. S. Tashiro

Ionic concentrations that control the viscosity of erythrocyte suspensions in aqueous solutions of organic salts. Yosio Egami. *J. Chosen Med. Assoc.* 29, 984–1003 (French abstr. 71–2)(1939).—The concns. of org. salt solns. that influence the viscosity of erythrocyte suspension

are more significant when expressed by their theoretical ionic concns. than the actual. S. Tashiro

A few urinary constituents of healthy Koreans. S. S. Kin and H. K. Lee. *J. Chosen Med. Assoc.* 29, 1004–8 (English abstr. 62–3)(1939).—Av. of analysis of 45 male and 36 female healthy young Koreans shows that as compared with Occidentals, the sp. gr. of urine is slightly lower, total acidity is about ½, total solid is lower and NaCl about twice as much. S. Tashiro

Functional alteration. Changes of splenic and parathyroid functions by administration of specific hormones and their mutual relationship. Ariyesi Mori. *J. Chosen Med. Assoc.* 29, 1307-23(German abstr. 86)(1939).—If a large amt. of splenic ext. is given to rabbits, the splenic vein contains a substance which has the power to diminish blood platelets. When parathormone is injected, the parathyroid produces a compd. which has the power to diminish blood Ca. When parathyroid is transplanted or its hormone is given, the splenic function is suppressed, the effect being neutralized after parathyroidectomy When the spleen is transplanted, or its ext. is given, parathyroid hormone diminishes, but becomes increased after splenectomy. S. Tashiro

Nephrohormone and its variation. Benzo Masuda *J. Chosen Med. Assoc.* 29, 1466–90(German abstr. 95–7)(1939).—The nephrohormone which has the power to decrease blood cholesterol and which is produced by the tubules is present in the renal cortex, but not in the medulla. It disappears after the sympathetic nerves are cut. After sympathectomy, there appears in the renal veins and cortex a substance which has the power to antagonize the nephrohormone. This substance is a protein-like substance, identical with Tokunitsu's contra-nephrohormone; it is also produced by the tubules. S. Tashiro

Specificity of hemoglobins I. Mituko Yasaki. *J Chosen Med. Assoc.* 29, 1504–40(German abstr. 98–9)(1939).—Serological studies. S. Tashiro

Secretion of sex hormones during the embryonic stage. I. Male sex hormone. Yositura Atumi. *J. Chosen Med. Assoc.* 29, 1541–62(English abstr. 99–100)(1939).—A male hormone appears in the umbilical artery of the ox embryo at the 6th month of pregnancy (60 cm.) It is absent in the blood of the umbilical vein and carotid artery of the mother. It appears in the testicles of the embryo at the 46-cm. stage (5 months' pregnancy). This compd. is a sterol deriv. and not identical with gonadotropic hormone of hypophysis. **II. Female sex hormone.** *Ibid.* 1563–92(English abstr. 100)—A female hormone appears in the umbilical artery of the cow embryo at the 63-cm. stage (7th month of pregnancy). S. Tashiro

Influence of experimental nasal obstruction on gastric secretion. Koiti Yuasa. *J. Oriental Med.* 30, 601–15 (German abstr. 176)(1939).—Analysis of gastric juice in Pavlov's stomach pouch shows that closing of both nostrils of dogs reduces the amt. of the secretion and free and total acidities, the digestive power decreasing to one-half. S. Tashiro

Histochemical study of the chick embryo. II. Vitamin C content. Seiti Suzuki. *J. Oriental Med.* 30, 1123–39 (English abstr. 282–4)(1939); cf. *C. A.* 33, 3442[6]. The titration method of 2,6-dichlorophenolindophenol is used and vitamin C is found to appear at the 3rd day of incubation (0.0147 mg.). At the end of the 10th day, it rose to 0.3386 mg. Of few organs exptd., the liver shows the greatest rate of increase of vitamin C, although the brain contains the highest amt. of all from the beginning to the 20th day. S. Tashiro

The influence of hydrogen ions on x-ray effect on antuitary hormone in pregnant woman's urine. Tadahumi Mabuti. *J. Oriental Med.* 31, 179–203(German abstr. 19–20)(1939).—So-called antuitary hormone found in the pregnant woman's urine is partly decompd. by a strong dose of x-ray, the effect being greater in the urinary pH is less than 7. Prolan A is activated by acid and inhibited by alkali, while prolan B is just the opposite. Both prolans suffer practically no effect of x-ray S. T.

Where does vitamin C in the various ocular tissues originate? Diffusion from the blood stream and synthesis in the lens. Hans H. Podestá and Joachim Baücke. *Arch. Ophthalmol.* (Graefe's) 139, 720–31(1938). Frank Urban

Results of autotransplantation of the cornea into the anterior chamber: their significance regarding corneal nutrition. Trygve Gundersen. *Trans. Am. Ophthalmol. Soc.* 36, 207–13(1938).—Corneal epithelium does not live when nourished only by the aqueous and excluded from its tear supply. Under these conditions the corneal stroma lives for a prolonged period; the so-called endothelium not only lives, but proliferates. Frank Urban

The gonadotropic content of the female rat hypophysis in experimental precocious puberty. Henry D. Lauson. *Am. J. Physiol.* 127, 629–36(1939); cf. *C. A.* 33, 2577[9].—The gonadotropic content of pituitaries from immature female rats in which precocious puberty had been induced by gonad-stimulating hormone was studied. The hypophyseal potency was inversely proportional to the degree of sexual development. In all cases in which the wt. of the ovaries exceeded 20 mg., the potency was reduced 33 to 40% below control level. E. D. Walter

The specific dynamic action of protein in sympathectomized cats. H. Haimovici. *Am. J. Physiol.* 127, 642–8(1939).—The results indicate that the sympathetic system does not play any part in the producing of the sp. dynamic action of proteins. E. D. Walter

A qualitative study of normal gonadotropin. Fred E. D'Amour. *Am. J. Physiol.* 127, 649–53(1939).—Normal gonadotropin was found to be similar in its effects to menopause urine. A tentative explanation of the mechanism of ovulation in the human is suggested. E. D. Walter

The glucose and lactic acid exchanges during hypoglucemia. H. E. Himwich, J. F. Fazekas and Sarah Nesin. *Am. J. Physiol.* 127, 685–8(1939); cf. *C. A.* 33, 5512[9].—The glucose and lactic acid exchange of liver, intestine and muscle were studied during hypoglucemia. During hypoglucemia the liver is continually supplying the blood with glucose and the lactic acid exchanges of the various organs are negligible. E. D. Walter

Gonadotropic hormone in the nonpregnant mare. H. H. Cole and H. Goss. *Am. J. Physiol.* 127, 702–9 (1939).—Gonadotropic hormone is present in the blood serum of nonpregnant mares at all phases of the estrous cycle. The hormone could not be distinguished biologically from that found in the pregnant mare. The highest concns. of hormone were found in mares with prolonged cycles or in mares which failed to come to estrus during the observation period. E. D. Walter

The effect of extracts of the adrenal glands on the respiration of isolated brain and liver slices. S. R. Tipton. *Am. J. Physiol.* 127, 710–15(1939).—Exts. of the adrenal whole gland and cortex depressed the O consumption of brain and liver slices of normal and of 3 adrenalectomized rats. The R. Q. of the brain slices was not affected by the ext. An ext. of beef brain also showed depressing effects on the respiration. Cryst. corticosterone in concns. of the same magnitude as the solid matter of the adrenal exts. also showed marked depressing action. E. D. Walter

The effect of the ingestion of glycine, with and without urea, upon creatine-creatinine excretion in the rat and man. Howard H. Beard, Julia K. Espenan and Philip Pizzolato. *Am. J. Physiol.* 127, 716–21(1939); cf. *C. A.* 33, 2571[9].—When glycine is fed to rats, urea can be supplied for the creatine synthesis, and when urea is fed, glycine can be supplied for the same purpose. When glycine is ingested by man, urea can be supplied for the synthesis of the guanidine group of both creatine and creatinine; when urea is ingested, glycine can be supplied for the synthesis of the acetic acid framework and Me group of these substances. It seems probable that in man, both creatine and creatinine can be synthesized from urea and glycine when they are ingested separately or together. E. D. Walter

Ketone body-total carbohydrate utilization ratios and

their relation to the problem of ketosis. J. A. Dye and Jane L. Chidsey. *Am. J. Physiol.* **127**, 745–50(1939).—The rate of ketone body utilization by the tissues is not influenced by the blood-sugar level, the utilization of total carbohydrates, evisceration or pancreatectomy, but by their own concns. in the blood and tissues. The existing evidence for and against the ketolytic and antiketogenic theories of carbohydrate action in relieving ketosis is discussed. The antiketogenic theory is favored. 1
B. D. Walter.

Effect of mare serum hormone on the male and female mouse. Wm. F. Starkey and James H. Leathem. *Am. J. Physiol.* **127**, 751–4(1939).—Mare serum hormone is capable of producing a stimulating effect on the gonads of male and female mice 12 days old. Ovarian wt. increase resulted in mature and immature female mice. Follicular maturation was induced with a few cases of only follicle stimulation but the formation of lutein tissue was predominant. Testis wts. remained unaltered in all males. 2
E. D. Walter

Properties of the substance liberated by adrenergic nerves in the rabbit ear. J. H. Gaddum and H. Kwiatkowski. *J. Physiol.* **96**, 385–91(1939); cf. *C. A.* **33**, 7548.—The evidence that the substance liberated by the adrenergic nerves in a perfused rabbit ear is adrenaline is strengthened by the observation that it stimulates the frog heart and constricts the vessels of the rabbit ear. Estimates of the adrenaline equiv. obtained by these 2 tests agreed with colorimetric estimates. E. D. W. 3

The hematological changes caused by the skin hormone "Esophylaxin." V. Esophylaxin and serum calcium. Seikan Kin. *J. Med. Coll. Keijo* **8**, 400–19 (1938).—The serum Ca content decreased markedly after the injection of Esophylaxin, and the reticuloendothelial system, parathyroid and spleen are necessary for the action of Esophylaxin. I. S. Yun 4

H. GIDEON WELLS

Conservation of some immunobiological properties of blood by means of glucose-citrate and concentrated citrate solutions. I. M. Mstiboskiĭ. *Méd. exptl.* (Ukraine) **1939**, No. 2, 12–16.—Human subjects were immunized by means of streptococcic vaccine, toxin or combined antigen (vaccine and toxin). Conservation of blood by the addn. of small quantities of strong citrate solns. was more effective in preserving the immunobiol. properties of the blood than the addn. of larger quantities of more dil. solns. of citrate. Use of 30% citrate preserved the immunobiol. properties of the blood for 5 days. 6
S. A. Corson

Immunobiological state of scalded patients immediately after the accident. M. I. Kanekevich. *Méd. exptl.* (Ukraine) **1939**, No. 2, 17–23.—Of 65 patients with burns, 80% showed a complete absence of agglutination, 16% showed a pos. reaction (dilu. 1:50), and 4% showed a pos. reaction (dilu. 1:100). Complete absence of complement was found in 22% of the patients, a low titer (0.2–0.1) in 49% and a 0.1–0.04 titer in 29% of the patients. A low phagocyte no. (0–5.0) was exhibited by 43% of the patients, 52.5% had a phagocyte no. of 5–10, and only 4.5% showed phagocyte nos. above 10. Twenty-six % of the subjects had a low opsonic index (up to 0.5), 63% had an opsonic index of 0.6–1.0, and only 11% had an opsonic index above 1.0. It is suggested that rational therapy, among other things, should attempt to stimulate immunogenesis in patients with severe burns. S. A. C. 7

Parasympathetic mediator and cholinesterase during functional disturbances of the autonomic nervous system. E. N. Berger. *Méd. exptl.* (Ukraine) **193.**, No. 2, 58–65.—Observations were made on 40 patients and on 28 healthy human subjects. The concn. of acetylcholinesterase in the blood varied for different subjects but was fairly const. for each individual. Many of the patients with increased activity of the parasympathetic system showed an increased blood content of acetylcholine and of its esterase. Therefore, the presence of greater quantities of acetylcholine is ascribed to an increase in its rate of production, the increase in esterase content being a compensatory phenomenon. S. A. Corson 8

Comparative study of the composition of certain compounds and their relation to immunity. Anastasios A. Christomanos. *Chim. Chronika* (Greece) **4**, 157–63 (1939)(in Greek).—A discussion of certain org. compds. in the light of Ehrlich's theories of immunity. Lucien Y. Dyrenforth 9

Antistaphylococcus immunization with an antigen prepared with aqueous solutions of essential oils. F. de Potter. *Compt. rend. soc. biol.* **131**, 1322–4(1939); cf. *C. A.* **33**, 6524⁸.—Cultures of *Staphylococcus aureus* were treated with geraniol, borneol or oil of cypress 2 days at 37° or 4 days at 20° (this killed the organisms) and then centrifuged. Guinea pigs were successfully immunized by injecting 1–2 cc. of the clear liquid subcutaneously or intracutaneously. L. E. Gilson 10

Recently discovered carcinogenic and anticancer agents. John A. Sampey. *J. Chem. Education* **16**, 461–6(1939).—Review with 151 references. E. H. 11

Studies on the blood-sugar content during fever. Iwao Ohtake. *Japan. J. Exptl. Med.* **17**, 249–67(1939) (in English).—Healthy rabbits exposed to the rays of a radiothermic app. for 30 min. showed a 9% increase. Lengthening of the exposure time showed a corresponding increase. The injection of typhoid, dysentery, vaccine, S or tetranydronaphthylamine caused a hyperglucemia. The blood-sugar content of human subjects during the fever period of various diseases varied according to age. Those over 50 gave the largest increases, while those under 11 gave inconsistent results. Typhoid and paratyphoid caused hyperglucemia in groups of all ages. Charles Jarowski 12

The liver and diabetes. L. S. Shvarts. *Klin. Med.* (U. S. S. R.) **17**, No. 4, 41–7(1939).—The depletion of liver glycogen, which runs parallel to the severity of diabetes, can be easily demonstrated by adrenaline-sugar curves. A depletion in mild or fairly severe cases of diabetes can be traced to hepatogenic or pancreatogenic factors. The depletion affects the functional capacity of the liver, resulting most often in a reduction of urea formation. S. A. Karjala 13

Effects of extract of human urine on tumors in mice. Floyd C. Turner. *U. S. Pub. Health Repts.* **54**, 1855–63 (1939).—A growth-inhibiting substance derived from human urine prevented, to a limited degree, the formation of tumors in mice after injection of cancerigenic chemicals, but the urinary deriv. had little, if any, specific inhibiting effect on transplanted or spontaneous tumors in mice. J. A. Kennedy 14

Physicochemical equivalents in shock. II. Surface tension of serum in insulin shock. I. Scimone. *Arch. sci. biol.* (Italy) **24**, 303–10(1938).—No appreciable difference in static and dynamic surface tension was found in the serum of schizophrenic patients subjected to insulin shock except a slight diminution when the serum was dild. 10 times. P. F. Metildi 15

Gas metabolism after blood transfusion in normal and fasting dogs. Virgilio Martini. *Arch. sci. biol.* (Italy) **24**, 503–16(1938).—In fasting dogs blood perfusion does not increase O_2 consumption. In the same animal blood obtained in the fed-absorbing period and reinjected in the same recipient produces a large gas hypermetabolism. P. F. Metildi 16

Adrenaline. IV. Adrenaline in the blood in arterial hypertension. Cesare Giordano and Pietro Zeglio. *Arch. sci. med.* **68**, 1–30(1939); cf. *C. A.* **33**, 8760⁸.—The adrenaline in normal persons amounts to maximally 3 γ per cc. blood and to 3–4 γ in the plasma. Higher concn. was found in 13 out of 27 cases of essential hypertension, in one out of 12 of secondary nephrosclerosis and in 5 out of 15 patients with hyperthyroidism. There was no direct relationship between adrenaline content and max. or min. pressure. Protein therapy always caused a 17

decrease of the adrenaline level but the reduction in blood pressure was not parallel. Insulin caused a sharp increase in adrenaline which varied with the initial level.
A. E. Meyer

Sulfur in the blood and liver diseases. Paolo Larizza. *Biochim. terap. sper.* **26**, 289-96(1939).—In liver disease there is a moderate increase of the inorg. S in the serum but not in the erythrocytes. The latter show an increment in org. nonprotein S and a decrease in the protein S. The changes are caused by a disturbance of the S-fixing function of the liver and a reduction of the albumin fraction in the blood in favor of the globulin fraction of lower S content. A. E. Meyer

Biochemistry of hypoglucæmic shock. I. The chlorides in plasma and corpuscles. Filippo Romeo. *Biochim. terap. sper.* **26**, 325-37(1939).—The Cl in total blood as well as in the plasma is conspicuously increased especially in cases with lethal prognosis. An increase of Cl in the erythrocytes persists to the end of shock in nonserious cases, whereas there is a final decrease in grave cases. A theoretical discussion is given. A. E. Meyer

The precipitating power against normal human serum of serum from rabbits injected with alcoholic precipitate of normal human urine. R. Waitz. *Bull. acad. méd.* **121**, 131-5(1939).—Normal human urine has marked antigenic power. The ppt. prepd. with EtOH produces precipitins in the rabbit specific to human serum.
A. E. Meyer

Experimental production of prostatic adenoma. Gabriel Petit, Pierre Gley and Étienne Béraut. *Bull. acad. méd.* **121**, 430-44(1939).—Immature dogs were treated with 1000 units of estradiol benzoate daily. Prostate as well as prostatic urethra soon showed signs of stimulation. The prostate itself acquired finally the size and structure of that of the adult animal but did not form an adenoma. The urethra showed proliferation of the epithelium, formation of new glands and development of a structure with all the characteristics of adenoma.
A. E. Meyer

Cancer and dehydroascorbic acid with open lactone ring. The effects of complex iron-sodium salts prepared from the acid on certain clinical features of the neoplastic process. L. Bérard, A. Morel, F. Arloing, A. Josserand and L. Perrot. *Bull. acad. méd.* **121**, 451-6(1939).—Salts of dehydroascorbic acid with Na and Fe were prepd. contg. 11.5, 18.0 and 21.5% of the latter, most as Fe^{+++} but also a small quantity as Fe^{++}. The prepns. were kept as a paste with EtOH and were used dissolved in 0.8% NaCl soln. The daily intravenous dose was 0.02 g. (Fe?). General subjective improvement was obtained, subsidence of pain and reduction of the tumors, facilitating prepn. for surgery. A. E. Meyer

Relation of the iodine contents of water, milk and pasture to the occurrence of endemic goiter in two districts of England. I. Introduction. John B. Orr, *et al.* *Med. Research Council* (Brit.), *Special Rept. Series* No. **217**, 5-7(1936).—The enquiry was designed to provide more definite information concerning the supposed relationship of environmental deficiency of I to the occurrence of thyroid disease, especially to explain the remarkable difference in incidence of thyroid enlargement among school girls in 2 counties. In Suffolk, the incidence was 3%, while in Somerset it was 56%. Results of the investigation show that environmental deficiency of I, as indicated by the I content of the local water, is assocd. with high incidence of goiter. However, in so far as the minor degrees of I deficiency are concerned, the actual amt. of I in the environment is not simply and directly related to the intensity of the incidence of goiter. **III. Analyses of water, milk and pasture samples for iodine. IV. Discussion. V. Summary.** M. G. Crabtree and E. M. Mason. *Med. Research Council* (Brit.), *Special Rept. Series*, No. 217, 13-20 (1936).—Winter, spring and summer samples of milk, water and grazing grasses were collected. The milk was preserved by adding 5 cc. of 10 *N* KOH, while the grasses were dried and ground. The method of Harvey (*C. A.* **29**, 8035[2]) was used for the detn. of I. Difficulty was encountered in the water analyses. No difference was found between the milk and grass from the 2 counties. The water showed 2.9 γ per l. in Somerset and 8.2 γ per l. in Suffolk. However, the environmental deficiency of I in Somerset is not so intense as to be solely responsible for the high incidence of goiter, and so the difference between the 2 counties cannot be solely due to the difference of I in their resp. waters. Insufficient intake of I is partly responsible for the high incidence of goiter in Somerset, but some other factor must be involved, such as the variation in the availability of soil I to herbage and hence to the animal population. Dorothy A. Meyer

The plasma lipides in arteriosclerosis obliterans. Nelsen W. Barker. *Ann. Internal Med.* **13**, 685-92(1939).—The plasma lipides in 73 such cases were compared with 200 normal individuals. The ranges of total lipide and of the fractions were essentially the same in both groups, but the mean values were higher in the patients with arteriosclerosis. This finding may aid in distinguishing between this condition and thromboangiitis obliterans, where the lipides are normal. John T. Myers

Acetone content in the urine of patients with lung tuberculosis. Kaoru Yamazaki. *Tohoku J. Exptl. Med.* **36**, 236-54(1939).—The av. daily urinary excretion of 10 healthy individuals was 12 mg. while that of 110 tuberculous patients was 16.87 mg. The graver the condition, the higher was the acetone excretion. Those patients who received a fat diet for a prolonged period showed an av. value of 17.41 as compared to 15.35 mg./day of those not ingesting an especially high-fat diet. Those cases which as a result of intake of abundant fat exhibited glucosuria had an av. urinary acetone excretion of 19.48 mg./day. Patients with normal temp. showed only slightly higher value than healthy subjects, but those with higher temp. showed an appreciable rise in urinary acetone. Thus, patients with a temp. under 36.9°, excreted 14.87, while those with temps. of 37-38, and 38.1-39.5° excreted 19.25 and 22.3 mg./day on the av. Fat-tolerance tests of healthy persons and of patients with pulmonary tuberculosis and glucosuria increased the acetone content of the urine on the av. by 12.7 and 34.2%, resp. It was also shown that increase in urinary acetone content paralleled the rate of sedimentation of erythrocytes. Twenty-seven references. Maurice M. Rath

Urine chloride concentration in patients with Cushing's syndrome. Abraham Cantarow. *Science* 90, 375-6 (1939).—Patients with Cushing's syndrome and with hirsutism (suspected hyperadrenalism) were unable to eliminate Cl in the urine in as high concn. as patients with various disorders not apparently assocd. with endocrine dysfunction. Felix Saunders

Insulin absorption as a circulatory test in children. H. Hungerland. *Monatsschr. Kinderheilk.* **78**, 157-67(1939). —0.2 units of insulin per kg. of body weight were injected subcutaneously above the lateral malleolus in children 5 to 15 years of age and the blood sugar was detd. with Hagedorn-Jensen's method after 30, 60, 120 and 180 min. on 2 consecutive days, first in a recumbent position and later in a sitting position. The results in 4 different groups of children can be summarized as follows (percentage deviation from fasting blood sugar):

	Group of children	Position	Insulin	9:30 a. m.	10 a. m.	11 a. m.	12 a. m.
I	Normal (40 cases; 1-12 years)	Not given	None	—	− 3	− 4	− 9
II	Normal (10 cases)	Recumbent	At 9:05	−10	−19	−25	−20
		Sitting	At 9:05	−13	−21	−22	−27
III	Cardiac decompensation (11 cases)	Recumbent	At 9:05	−13	−20	−26	−28
		Sitting	At 9:05	− 3	− 4	− 8	−10
IV	Asthenic, vasolabile, orthostatic (9 cases)	Recumbent	At 9:05	−14	−20	−20	−14
		Sitting	At 9:05	− 1	− 6	− 6	− 7

As compared with the normal group, absorption of insulin [1] dependent parts seemed to be deficient in the 2 ups with circulatory disturbances, although there was no way to differentiate between cardiac decompensation and peripheral vasolability with no cardiac insufficiency. H. P. G. Seckel

The pathology of sodium chloride metabolism. G. Fanconi. *Monatsschr. Kinderheilk.* 78, 1–35(1939); cf. *C. A.* 33, 7228.—Methods of testing the NaCl stability were described as consisting of: (1) exam. the level of Cl and Na in the serum, (2) performing NaCl-tolerance tests and (3) giving Liq. Kalii acetici per os (K-tolerance test). According to the distribution of NaCl in the organism, disturbances of NaCl metabolism can be classified as NaCl-congestion, NaCl-deficiency, and transmineralization. From the point of view of pathogenesis, they can be [2]

Minerals	Liver: Actual	Liver: Normal	Liver: % Deviation	Cutaneous blister: Actual	Cutaneous blister: Normal	Cutaneous blister: % Deviation
Dry substance	60 g. %	74.8 g. %	−20	—	—	—
Na	64 mg. %	98 mg. %	−24	193 mg. %	294 mg. %	−35
K	276 mg. %	320 mg. %	−13	20 mg. %	33 mg. %	−39
Cl	—	—		828 mg. %	373 mg. %	−12

tabulated as follows: I. Primary disturbances, due to failure (1) of the diencephalic-hypophyseal control, (*a*) manifest diabetes insipidus, (*b*) occult diabetes insipidus (hyperchloremia, fever in infants with the familial type); (2) of the cortico-adrenal control ("diabetes salinus" in Addison's disease; 5 puerile cases in the world literature!); (3) of the renal filter ("diabetes salinus renalis," e. g., in renal rickets); (4) of the cell-membrane filter ("serous inflammation," e. g., in lobar pneumonia); II. Secondary disturbances, due to (1) extrarenal NaCl-losses from hunger, perspiration, diarrhea, and particularly from severe vomiting as in pylorostenosis ("Coma pyloricum," Seckel), acetonemic vomiting, etc.; (2) flooding with demineralizing fluids, e. g., intravenous glucose injections; (3) alimentary demineralization, e. g., in celiac disease; (4) Cl-displacement from blood into tissue cells by acidosis, e. g., in diabetes, acetonemia, uremia, etc. Except for diabetes insipidus and celiac disease, all disturbances mentioned were shown to be characterized by hypochloremia. Each point was illustrated by most unusual case histories the details of which [3] were published by F. in *Ibid.* 44, 114(1939) and *Verhandl. Kongr. Inn. Med.* 1938. H. P. G. Seckel

Pseudo-chylous effusions. F. Horn. *Monatsschr. Kinderheilk.* 78, 36–44(1939).—The history of a 4-year-old boy with rheumatic polyserositis was reported in which the pseudo-chylous effusion was not caused, as is generally supposed, by a fatty emulsion. The chem. analyses were given in a table:

	Pleural effusion (pseudo-chylous)	Ascites (almost clear)	Blood (clear)
Sp. gr.	1010	1006	—
Reaction	neutral	neutral	-
Ether-sol. parts	0.2395 g. %	0.1846 g. %	- -
Nonprotein N	28 mg. %	18 mg. %	43 mg. %
Proteins	1.4 g. %	1.32 g. %	5.[illegible] g. %
Cholesterol	none	none	157 mg.
Ca	6.3 mg. %	6.8 mg. %	10 mg. %
P	3.35 mg. %	3.59 mg. %	4.3 mg. %
Chlorides (as NaCl)	165 mg. %	150 mg. %	298 mg.

On the basis of over 30 reports from the literature the conclusion was drawn that the pseudo-chylous character of an effusion has no specific diagnostic value whatsoever. H. P. G. Seckel

The pathenogenesis of acetonemic vomiting. W. Goeters. *Monatsschr. Kinderheilk.* 79, 176–9(1939).—A fatal case of acetonemic vomiting (girl 3 years old) was described in which, between the 4th and 6th (last) day of sickness, the following chem. data were obtained: Acetone present in urine and exhaled air, blood (Na-)Cl 276 mg. %, spinal fluid sugar 112 mg. %, hemoglobin 96%, erythrocytes 5.1 millions. After large infusions of glucose and Ringer solns. and parenteral phenobarbital therapy the blood NaCl rose to 612 mg. % and the blood concn. fell. For the last 3 days, a watery-mucous-bloody diarrhea prevailed. At autopsy, only neg. findings were obtained except for a fatty infiltration of the liver and fat-free adrenals. No encephalitis was present on histological examn. of the brain. The fatal outcome was due to a severe disturbance of enteral absorption and exsiccosis (insufficiency of adrenal cortex?). H. P. G. S. [4]

Problems of exsiccosis in infantile toxicoses. V. Uher. *Z. Kinderheilk.* 61, 135–41(1939).—The livers of 9 infants, 3–6 months of age, who died of alimentary intoxication were analyzed, not more than 6 hrs. after death, for dry substance (at 110°), ash (at 600°), total N (Kjeldahl), Na (as K pyroantimonate), K (as Na cobalt-hexanitrite), Ca (as NH_4 oxalate) and Mg (with hydroxyquinoline). Similar studies were made in the watery contents of cantharis blisters produced on the skin of intoxicated infants. The max. diminutions of the various minerals in the 2 series of expts. are:

Ca and Mg contents of the liver were about normal average (12 and 15.4 mg. %, resp.) as were those of the cutaneous blisters (10 and 3 mg. %, resp.). The loss of Na, indicating a loss of extracellular water, was predominant in the milder cases of toxicosis whereas in the severe cases the loss of K, indicating a loss of intracellular water, was even greater than that of Na. The physicochem. significance of this transmineralization for the problem of exsiccosis was discussed. H. P. G. Seckel

The effect of vitamin B_1 on serum anaphylaxis. Sei Syoku Kin and Hei Ki Lee. *J. Chosen Med. Assoc.* 29, 381–5(English abstr. 21–3)(1939).—The injections of vitamin B_1 into guinea pigs reduces not only the symptoms of horse serum anaphylaxis shock, but also delays death. This effect was obvious with a large single injection of 0.25–0.5 cc. (1 cc. = 100 pigeon unit) at one hr. before reinjection, or with a daily injection of 0.1 cc. during the initial and reinjection periods. S. Tashiro [5]

Fluoride poisoning: Mottled enamel formation in rats fed with hot spring water. Yutaka Sugawa. *J. Chosen Med. Assoc.* 29, 1491–1503(English abstr. 97–8)(1939). The mottled enamel, endemic in some hot-spring areas of Korea, is shown to be due to the drinking of hot spring water which contains 6.4–9.2 per million F. The rats given concd. water of these springs or artificial spring water with NaF added produce chalk-white color on labial surface of lower incisors after 11–35 days, and transversal strips after 43–67 days. S. Tashiro [6]

Cholesterol content of myxosarcoma of fowl. Yutaka Uehara. *J. Chosen Med. Assoc.* 29, 1595–5(German abstr. 101)(1939).—The free cholesterol content of myxosarcoma 20 days after transplantation is on the av. 0.019 g. per 15-g. sample; that of myxosarcoma after daily injection of 10 cc. of Ringer soln. (per kg.) is 0.018 g., and that of myxosarcoma after daily injection of the Ringer soln. plus histotoxine is 0.012 g. The conjugated cholesterol content, too, is less in the tissues when histotoxine is injected. S. Tashiro [7] [8]

Skin diseases and vitamin C. II. Intradermal test with 2,6 dichlorophenolindophenol. Seiiti Suzuki. *J. Oriental Med.* 30, 971–86(English abstr. 267–9)(1939).—The time of decolorization of the Rotter skin test with 2,6-dichlorophenolindophenol is inversely proportional to the ascorbic acid content of blood serum, as tested with healthy human subjects and pathol. cases with skin diseases. It is relatively shorter in rabbits than guinea pigs, showing that the former have more vitamin C. S. Tashiro [9]

Formaldehyde-gel reaction. I. Biological studies. Kaoru Mori. *J. Oriental Méd.* 30, 1063–77(German abstr. 278)(1939).—Factors influencing CH_2O-gel reaction are dctd. with 181 samples of serum of various diseases. The optimum amt. of 35% CH_2O is 1 drop to each 1-2 cc. serum; evapn. of H_2O and CH_2O must be prevented; it is best to keep the tube in the dark. Serum irradiated

with ultraviolet gives a stronger reaction; this suggests that a globulin must be responsible for this reaction. S. Tashiro

Cause of endemic goiter. I. The effect of continuous administration of "Goiter water" on the thyroid of guinea pig. Tokihiko Kurata. *J. Oriental Med.* **31**, 1–11 (English abstr. 1) (1939).—When 1–10 cc. of the water obtained from a goiter district (Jehol) is given daily to guinea pigs of nongoiter district (Mukden), the thyroid begins to enlarge after 3 months, showing every symptom of a goiter after 5–6 months. The similar feeding with the water boiled for 30 min. at 100° does not produce the disease. There is a pos. goitrogenic substance in the "goiter" water which is destroyed by boiling. S. Tashiro

Kaschin-Beck disease. III. Hydrogen-ion concentration and acid-combining power of the blood of patients with Kaschin-Beck disease. Taro Yamanaka. *J. Oriental Med.* **31**, 113 25(German abstr. 10–12) (1939).—The blood of pH of these patients is within the normal limit, but the acid-combining power is less. Their blood shows a compensated primary alkali deficit. S. Tashiro

Quantum mechanical resonance attraction and the problem of immunity reactions. P. Jordan. *Z. Physik* **113**, 431–8(1939).—Empirical facts concerning the "active groups" of immunizing "antigens" are discussed from the point of view of whether quantum mech. resonance attraction is applicable to the explanation of serological reactions. It is pointed out that the antigens and antibodies must consist of complex mols. This is discussed, especially from the viewpoint of active groups. The quantum mech. aspects of resonance attraction are discussed. S. Tolansky

The effect of vitamin C on the production of antibodies. I–II. T. Izutumi and I. Sawai. *Japan. Z. Mikrobiol. Path.* **33**, 175 86(1939).—The productions of agglutinin, precipitin and hemolysin was accelerated by the continuous injections of vitamin C. I. S. Yun

The influence of lipoid and bile addition to antigen on the production of agglutinin. M. Isikawa. *Japan. Z. Mikrobiol. Path.* **33**, 1026 33(1939).—The author found that the production of agglutinin was increased by the addn. of lipoid or bile to antigen. I. S. Yun

Presence of an anemic substance in the blood of a patient suffering from anchylostomiasis. Masanori Yamada. *J. Med. Coll. Keijo* **8**, 391 9(1938).—Y. demonstrated the presence of an anemic substance in the blood; it is different from the worm toxin. I. S. Yun

The presence of anemic substance in the blood in pernicious anemia. Mutuyosi Anan and Keisyaku Kin *J. Med. Coll Keijo* **8**, 421 30(1938).—Blood from a patient who had pernicious anemia injected into the ear vein of normal rabbit in the amt. of 2 cc. per kg. of body wt. of the rabbit caused a drop of 1.5–2.0 million per cubic mm. in the red-cell count within 2–6 hrs. after the injection. The same effect was produced in a splenectomized rabbit. There is a specific anemia-producing substance present in the blood in pernicious anemia, which may be elaborated by some organ in the patient. S. S. Yun

H—PHARMACOLOGY

CARL F. SCHMIDT

A preliminary note on the chemotherapy of oesophagostomiasis of sheep with special reference to the efficiency of phenothiazine. Hugh McL. Gordon. *J. Council Sci. Ind. Research* **12**, 203–6(1939).—Phenothiazine, in doses approximating 0.2 g. per kg. of body wt., offers great promise for the treatment of oesophagostomiasis in sheep. Satisfactory results can be obtained without the necessity for insuring that the drug passes direct to the abomasum if a large enough dose be given. Phenothiazine is claimed to be relatively nontoxic and the preliminary expts. show no loss of wt. or appetite among the treated sheep. J. R. Adams

A preliminary note on the anthelmintic efficiency phenothiazine against Haemonchus contortus in sheep. Hugh McL. Gordon and L. K. Whitten. *J. Council Sci. Ind. Research* **12**, 207(1939); cf. *C. A.* **33**, 8823[8].—Doses of 0.3 to 0.75 g. of phenothiazine per kg. of body wt. administered in capsules on 3 successive days showed a 100% anthelmintic efficiency against *H. contortus*. Even a single dose appeared to possess a high degree of efficiency. There was a sufficient concn. of phenothiazine in the feces to destroy the developing preinfective larvae. J. R. A.

A preliminary note on the treatment of oesophagostomiasis in sheep with phenothiazine. F. H. S. Roberts. *J. Council Sci. Ind. Research* **12**, 208 (1939).—Encouraging results were obtained with 5 grown sheep, each of which had received 4 g. of phenothiazine suspended in 1 oz. of 1% Cu sulfate soln. and with heavily infected lambs 4 to 5 months old, each of which had received 2 g. of powder suspended in a little liquid paraffin, after administration of 2 cc. of 10% Cu sulfate soln. No sign of toxicity followed the above dose rates. J. R. Adams

Toxicology of fluorides. Alexander O. Gettler and Lester Ellerbrook. *Am. J. Med. Sci.* **197**, 625–38(1939). After examn. of existing qual. tests for the detection of F in human tissues, there was devised a simpler method based on the pptn. of the La salt from a HNO_3 ext. of tissue and the formation of crystals of Na fluosilicate by the addn. of powd. glass. Examn. of quant. methods indicates that the Th nitrate-alizarin volumetric method is best adapted from a standpoint of accuracy, sensitivity and simplicity of technique. The normal F content of the various human organs and tissues, the distribution of the F among the various organs and body tissues of fatal fluoride cases, and the min. lethal dose of absorbed flubride were detd. 77 references. Ruth E. Black

Iontophoresis. Milton A. Lesser. *Am. Professional Pharmacist* **5**, 559–62, 591(1939).—A review dealing with this form of therapy whereby medication with cholines, histamine, Ca, Ag and Cu is effected. 22 references. H. M. Burlage

Sulfanilamide in tuberculosis: An explanation of certain findings. H. J. Corper, Maurice L. Cohn and Clarence Bower. *Am. Rev. Tuberc.* **40**, 452–66(1939). Large doses of sulfanilamide for long periods of time, given parenterally as well as enterally, begun before or coincident with infection of guinea pigs with virulent human tubercle bacilli, have an apparent, though not real, effect upon the org. tuberculous involvement of these animals which is most strikingly evident in the spleen. These findings explain the earlier studies on enteral treatment by Rich and Follis (*C. A.* **32**, 3029[7]) and those of Greey, *et al.* (*Proc. Soc. Exptl. Biol. Med.* **39**, 22(1938)), which could not be verified by parenteral sulfanilamide treatment studies. The apparent effect noted upon the tuberculosis in the guinea pig is explained as an org. toxic effect of the sulfanilamide since it can also be noted when heat-killed and avirulent human tubercle bacilli are given intravenously in large amts. to animals which are treated as compared with untreated controls. Sulfapyridine was also tested with essentially the same effects. Even in larger doses, sulfanilamide has no appreciable effect upon the spread of tuberculosis in guinea pigs infected by various routes and in various ways with virulent human tubercle bacilli; such effect as is seen can be entirely explained on the basis of the toxic effect of the sulfanilamide and not upon a retardation of the tuberculosis. In elaboration of the view expressed by Shecket and Price (*J. Am. Med. Assoc.* **112**, 823(1939)) that "the use of sulfanilamide in conditions in which its value is not established should be reserved for cases under institutional direction," and that the drug should not be used for long-duration administration, is added that misinterpretation of the effect in chronic diseases especially be avoided by carefully controlled exptl. studies considering the org. toxic action of the drug before application to human treatment. H. J. Corper

Pharmacodynamic study of red squill. A. Tournade, P. Fourment, H. Roques and G. Chardon. *Compt. rend. soc. biol.* **131**, 1204–6(1939).—Infusion of red squill, injected as previously described (*C. A.* **33**, 7489[8]), produces at first a mild hypertension owing to general vaso-

constriction and a slowing of the heartbeat by an action on the medullary nerve centers, and an increase in respiration. Later, as death approaches, the respiration fails and the blood pressure rapidly decreases to zero.
L. E. Gilson

Comparative effects of acetylcholine and direct current on striated muscle. Action of cold and calcium ions. P. H. Benoit and M. Beauvallet. *Compt. rend. soc. biol.* **131**, 1247–50(1939).—After treatment with eserine the isolated sartorius muscle of the frog responds with the same type of contractions to acetylcholine and to prolonged d.-c. stimulus. Decreasing the temp. or increasing the Ca conen. of the Ringer soln. bathing the muscle raises the threshold of sensitivity to either type of stimulus.
L. E. Gilson

Sensitivity of the epoöphoron to testosterone as detected by the colchicine reaction. F. Granel. *Compt. rend. soc. biol.* **131**, 1255–6(1939).—In adult female guinea pigs the injection of 15 mg. testosterone in 15 days has little or no effect on the ovaries, uterus and clitoris but produces a marked hypertrophy of the epoöphoron. Rapid cell division can be detected after the injection of colchicine.
L. E. Gilson

Substances which protect from the toxic action of histamine. Role of glucose. Jean Brunati. *Compt. rend. soc. biol.* **131**, 1256–60(1939). Five mg. of procaine protects the guinea pig from a lethal dose of histamine; 0.25 mg. adrenaline has little or no protective action. A preliminary injection of glucose affords complete protection. Antipyrine increases the toxic action of histamine. 4
L. E. Gilson

Cardiovascular action of urea. Vasodilator action. Action of urea on the contractility of the myocardium. Marin Pavesco. *Compt. rend. soc. biol.* **131**, 1267–70 (1939); cf. *C. A.* **33**, 5506⁸.—Intravenous injection of urea produces intense peripheral vasodilation in rabbits. A 0.5–2.0% soln. of urea in Ringer soln. increases the amplitude of the contractions of the isolated frog heart. 5
L. E. Gilson

Utilization of the electroencephalographic method for the pharmacological localization of evipan [in the brain]. Zénon Drohocki and J. Drohocka. *Compt. rend. soc. biol.* **131**, 1287–91(1939). L. E. Gilson

Modifications of the reaction of the heart to acetylcholine or vagus excitation in presence of sodium bicarbonate. M. Segers. *Compt. rend. soc. biol.* **131**, 1294–6 (1939).—$NaHCO_3$ has little effect on the inotropic and dromotropic actions of acetylcholine or vagus excitation on the frog heart *in situ* but causes a temporary disappearance of the chronotropic action. L. E. Gilson 6

Comparative action of estradiol and dihydroxydiethylstilbene on the pH of human vaginal secretion. J. A. Schockaert, Georges Delrue and Jacques Ferin. *Compt. rend. soc. biol.* **131**, 1309–11(1939).—Small doses of either compd., injected intramuscularly or taken orally, cause a slight decrease in the pH. L. E. Gilson 7

Alkyl nitrites. III. A pharmacologic study of a new series of organic nitrates. John C. Krantz, Jr., C. Jelleff Carr, Sylvan E. Forman and Fred W. Ellis. *J. Pharmacol.* **67**, 187–90(1939); cf. *C. A.* **33**, 7422.—The dinitrates of isomannide, isosorbide and erythritan and the tetranitrates of styracitol, polygalitol, mannitan and sorbitan were prepd. from the corresponding sugar alc. anhydrides. Compared to erythritol tetranitrate they produce a similar but more prolonged drop in blood pressure when injected intravenously in dogs. In general, these nitrates of the sugar alc. anhydrides are more water-sol. and less lipide-sol. than the nitrates of the undehydrated sugar alcs. 8

Isomannide dinitrate, $OCH_2CH(NO_3)CHCHCH(NO_3)-CH_2O$, is readily prepd. in pure cryst. form and is comparatively free from explosive properties. **IV. The pharmacology of isomannide dinitrate.** *Ibid.* 191–200.—Isomannide dinitrate produces a more prolonged depressor response in dogs and man than does glyceryl trinitrate, erythritol tetranitrate or mannitol hexanitrate. It is not hydrolyzed in the blood and does not produce detectable amts. of methemoglobin. It dilates the coronary vessels of the steer and rabbit *in vitro* and of the dog *in situ*. It can be readily prepd. in tablet form for the treatment of hypertension and angina pectoris. L. E. Gilson 9

Influence of disulfanilamide on experimental influenza infections. D. R. Climenko, M. L. Crossley and E. H. Northey. *J. Pharmacol.* **67**, 201–11(1939).—The absorption of disulfanilamide from the alimentary tract of the rabbit, dog or man is so small as to be practically negligible, but the Na salt (I) is rapidly absorbed. The max. conen. in the blood is reached in 3 hrs. or less, and the drug is completely eliminated in the urine within 6 hrs. The toxicity is very low. I in doses up to 1500 mg./kg. daily for 16 days produced no leg weakness or other bad effects. I exerts some protective action against moderate infecting doses of influenza virus in mice. Conens. up to 100 mg. %, in contact for a period of 1 hr., attenuated but did not completely inactivate virus suspensions *in vitro*. More prolonged contact inactivated the virus in some cases. L. E. Gilson

Effects of sulfanilamide on the lower vertebrates. J. T. Litchfield, Jr. *J. Pharmacol.* **67**, 212–23(1939).—The parenteral lethal dose of sulfanilamide for the spiny dogfish is about 100 mg./kg. For chickens the lethal oral dose is about 1 g./kg. The lethal dose for frogs is still larger and increases with the temp. Subtoxic blood levels at 18° become toxic levels at 5°. On the basis of blood conens. it is about 15 times as toxic for the fish as for the frog and about 4 times as toxic for the fish as for the bird. Absorption varies greatly with the mode of administration and in all cases excretion is slow. Conjugation occurred in the fish and chicken but not in the frog. Cyanosis was produced in chickens by chronic intoxication with sulfanilamide. A direct toxic action on the muscles of the frog was observed *in vivo* and *in vitro*. L. E. G.

Physiological adaptations in cardiac slowing by digitalis and their bearing on problems of digitalization in patients with auricular fibrillation. Harry Gold, Nathaniel T. Kwit, Harold Otto and Theodore Fox. *J. Pharmacol.* **67**, 224–38(1939).—Chiefly discussion. L. E. G.

Studies of certain addition characteristics of dihydromorphine ("paramorphan"), dihydrodesoxymorphine-D ("desomorphine"), dihydrodesoxycodeine-D ("desocodeine") and methyldihydromorphinonone ("metopon"). C. K. Himmelsbach. *J. Pharmacol.* **67**, 239–49(1939).—The above compds. were each substituted for morphine in 4 groups of addicted patients. Addiction satisfaction by the first 3 drugs was nearly complete, but decidedly incomplete with the fourth. Variations in intensity and duration of phys. dependence effects were detd. L. E. Gilson

Effect of fluidextract of ergot and of ergotamine on the emptying time of the human stomach. Edward J. Van Liere and Clark K. Sleeth. *J. Pharmacol.* **67**, 250–5 (1939). Two cc. of fluidext. of ergot caused an av. delay of 30% in the gastric emptying time of human subjects. One mg. of ergotamine caused an av. delay of 16.4%. Some of the other alkaloids in the fluidext. are probably more powerful in their action than is ergotamine. The action is probably directly on the stomach muscles and not through the autonomic nervous system. L. E. G.

Combination courses of bismuth administration. Torald Sollmann, H. N. Cole and Katherine Henderson. *J. Am. Med. Assoc.* **111**, 2175–9(1938).—A graded sequence of injections of soln. Bi (iodobismitol and sobismiol) with weekly injections of Bi subsalicylate produces a high initial conen. of Bi as reflected in the urinary excretion, which reaches at the end of 2 weeks a level of 4–12 mg. Bi per day. This form of Bi therapy is particularly useful in the acute stage of syphilis where the patient is sensitive to As.
F. P. Griffiths

Crystalline insulin. Alexander Marble and Ilmari Vartiainen. *J. Am. Med. Assoc.* **113**, 1303–10(1939).—Results from identical dosages of amorphous insulin and a soln. of Zn insulin crystals show a slightly prolonged action from the latter product. Limitation of the insulin on the market to (*a*) a rapidly acting insulin, such as

cryst. Zn insulin, and (*b*) a slowly acting variety, the protamine zinc insulin, is recommended. F. P. Griffiths

Chemotherapy. X. Colorimetric tests for aromatic hydroxylamines and for further oxidation products of aromatic amines. Their demonstration in the urine following sulfanilamide administration. Sanford M. Rosenthal and Hugo Bauer. *U. S. Pub. Health Repts.* 54, 1880–90 (1939); cf. *C. A.* 33, 8305¹.—Most of the sulfanilamide administered to man or animals can be recovered in the urine either free or acetylated. It is of importance to know whether any of it is oxidized during its passage through the body. If, e. g., a hydroxylamine is formed the bacteriol. action of the drug may be due, at least in part, to the fact that the hydroxylamines are active as inhibitors of catalase. It was of special interest to know whether the hydroxylamine deriv. of sulfanilamide is formed in the body. In studying methods for detecting this deriv., it was found that when 4-hydroxylaminobenzoic acid or 5-hydroxylaminobenzene sulfonamide reacts with HNO_2 a diazo compd. is formed which yields as intense color with the usual coupling agents. Moreover, a preliminary acetylation accomplished by shaking the soln. with Ac_2O prevents any free sulfanilamide from taking part in the diazo reaction. After the acetylation of the unchanged sulfanilamide, the soln. can be diazotized with $NaNO_2$ in the presence of NH_4 sulfamate and then some dimethyl-α-naphthylamine or some (1-naphthyl)-ethylenediamine dihydrochloride is added and after some time the color can be read in a colorimeter against suitable standards. The results of this method of analysis showed that after the oral administration of sulfanilamide to man, rabbits, dogs or rats appreciable quantities are found in the urine as hydroxylamine deriv. Glutathione and cysteine reduce 4-nitrosobenzoic acid to 4-hydroxylaminebenzoic acid and to 4-aminobenzoic acid but ascorbic acid reduces it almost entirely to the hydroxylamine. Bibliography of 15 titles. W. T. H.

Physiological observations following induced convulsions. Leo L. Orenstein. *N. Y. State J. Med.* 39, 1921–3(1939).—A study was made of circulatory changes in 15 schizophrenic patients given intravenous injections of metrazole. After a mild metrazole convulsion, the electrocardiogram showed rapid rate, arrhythmia, *T*-wave elevation and depression of the *S-T* segment. After a severe convulsion, the electrocardiogram also showed sinus arrest, shifting of the pace-maker auricular and ventricular premature contractions, coupling of beats, nodal escapes, and rarely a marked bradycardia. The blood pressure showed a rise in systolic and diastolic levels at the beginning of the injection and generally a fall in the diastolic and an elevation in the systolic level after a convulsion. The cerebrospinal fluid after a metrazole convulsion showed a marked rise in pressure and no change in content. When the metrazole was given too slowly to cause a convulsion, no notable effects were produced other than an increase in heart rate. E. J. C.

Theory and results of prophylaxis of endemic goiter in Switzerland. H. Eggenberger and F. M. Messerli. *West. J. Surg. Obstet. Gynec.* 47, 596–9(1939).—The successful use of iodized salt in combating endemic goiter in Switzerland is described. Salt contg. 10 mg. I per 1000 g. was more effective than salt contg. 5 mg. I per 1000 g. The daily dose of I found definitely to prevent endemic goiter is 0.1 mg. per person. E. J. C.

Fowl paralysis. Clifford W. Barber. *Cornell Vet.* 29, 41–4(1939).—Cold-pressed wheat-germ oil, administered orally in gelatin capsules at the rate of 1–2 cc. per bird per day, had no appreciable effect on the duration and severity of the disease. K. D. Jacob

The effect of sulfanilamide on bovine mastitis streptococci Ralph B. Little. *Cornell Vet.* 29, 287–94(1939).—When it was administered at the rate of 108–1261 g./cow, the drug failed to destroy the streptococci in the affected quarters, although during treatment the nos. of streptococci and leucocytes appearing in the milk were greatly reduced. In acute mastitis the drug may aid in alleviating acute symptoms, but repeated attacks may be expected to occur. K. D. Jacob

The effect of sulfanilamide on the course of experimental avian coccidiosis. P. P. Levine. *Cornell Vet.* 29, 309–20(1939).—Sulfanilamide fed at the rate of 0.3 g. daily to 1.5-lb. chickens had no effect on the course of infection with *E. tenella*. Similar treatment of birds infected with a mixt. of *E. mitis*, *E. acervulina* and *E. necatrix* prevented the development of oöcysts of the 1st 2 species but had no effect on the last. Likewise, the drug practically completely suppressed the discharge of oöcysts of *E. praecox*, *E. mitis*, *E. hagani* and *E. maxima*. A few days after the drug was discontinued, oöcysts appeared in the feces but the count reached a max. considerably below that of the control birds. When it was mixed in the mash in concns. of 0.1–0.5% by wt., sulfanilamide prevented the normal wt. gain of growing chickens. Concns. of 0.1–0.2% had no effect on the production and discharge of oöcysts of *E. hagani* and *E. praecox*, but a concn. of 0.3% had a marked inhibitory effect on the oöcyst discharge of birds infected with these species and *E. mitis*. K. D. Jacob

The effect of adrenaline and thyroxine on the absorption of oxygen by the sympathetic ganglion. V. M. Potapova. *J. Physiol. U. S. S. R.* 25, 805–11(in French, 811)(1938).—The absorption of O_2 by the isolated sympathetic ganglion of a cat after the injection of 0.1–8.5 cc./kg. body wt. of 0.1% adrenaline (I) and 0.25 mg./kg. body wt. of thyroxine (II) was increased by 83.5 and 58.5%, resp. No increase was observed on direct treatment of the ganglion *in vitro* with I or II. S. A. Karjala

The effect of neural and humoral heart stimulation. A. Solov'ev. *J. Physiol. U. S. S. R.* 25, 906–18(in English, 917–18)(1938).—Disharmony between the contractions of the auricles and ventricles of the heart can be brought about by stimulation of the "accelerating" nerve (I) and relieved by stimulation of the "reinforcing" nerve (II). When II is stimulated before I no disharmony or dissocn. occurs. Hearts of *Rana temporaria* with intact nerve connections were perfused with Ringer soln. and sep. kymograph recordings taken of auricular and ventricular contractions. The heart, with its vagal system previously inhibited by morphine (III), exhibits disharmony similar to the stimulation of I upon the injection of adrenaline (IV). This is readily relieved by stimulation of the vagus or injection of acetylcholine (V). If the morphinized heart is first treated with V no dissocn. is caused by IV. When IV and V are perfused through a normal heart in succession or simultaneously the cardiac activity resembles the work of a "trained" heart with low frequency and high amplitude of contractions. An increase in the T pike occurs, indicating an increased intensity of metabolic processes. The perfusate of the hind legs of winter frogs is vagomimetic (decreasing the amplitude of cardiac contractions and decreasing aortic pressure) while that of the hind legs of spring and summer frogs is sympathicomimetic (increasing the amplitude of contraction and increasing aortic pressure). S. A. Karjala

The influence of adrenaline and thyreoidin on the excitability of the cerebral cortex. N. I. Bondarev. *J. Physiol. U. S. S. R.* 25, 926–9(in German, 929)(1938).—Intravenous injections of 0.0005 mg./kg. of adrenaline (I) reduce the excitability (II) of the motor centers of the cerebral cortex. Smaller doses increase II. Subdural injections of I cause a sharp drop in II. The direct action of thyreoidin causes a reduction in II while intravenous injection sometimes increases and sometimes decreases II. S. A. Karjala

Alterations in the ammonia content and pH of brain tissue during excitation and depression of the central nervous system with certain pharmacological agents. E. A. Vlaumirova. *J. Physiol. U. S. S. R.* 25, 930–9(in English, 939)(1938).—The N of the av. preformed NH_3 in the brain tissue of normal mice is 0.43 mg. %. The values after the injection of camphor (I), NaBr and urethane were 0.63, 0.87 and 0.26 mg. %, resp. With I the increase in NH_3 is lowered in the stages of relative rest between convulsive fits. Little change from normal was observed in the pH of brain tissue during excitation of the central nervous system with the drugs. S. A. Karjala

The treatment of cutaneous lesions caused by war gases. Z. N. Grzhebin. *Klin. Med.* (U. S. S. R.) 17, No. 6, 83–6(1939).—A review. S. A. Karjala

Chemotherapy of experimental pneumococcus infection. II. N. G. Rabinovich. *Klin. Med.* (U. S. S. R.) 17, No. 6, 89–94(1939).—The injection of 0.08–0.1 cc. of 5% oil of camphor, 0.1–0.2 cc. of 1% quinine-HCl or a mixt. of 0.05 cc. and 0.1 cc., resp., of the 2 within 48 hrs. after the inoculation of mice with types II, III, XIV and XXII pneumococcus led to an increase in the survival rate in mice. The resistance of mice to infection by types I a. d II pneumococcus is increased by the injection of 0.2 cc. of normal horse serum before infection. S. A. Karjala

Hematopoiesis in chronic intoxication by mercury vapors. Alvaro Gori Savellini. *Rass. med. ind.* 10, 552–61 (1939).—A review of the literature since 1906 is followed by original expts. with 6 guinea pigs and 4 rabbits subjected to chronic poisoning and 10 guinea pigs subjected to subacute poisoning. Blood tests showed that subacute poisoning leads to a stimulation of the erythropoietic organs, compensated by a corresponding increase in blood destruction. The granulocytopoietic tissues are also stimulated and this is not compensated by increased destruction of the circulating granulocytes, the no. of which are increased. The lymphopoietic system is stimulated. In chronic poisoning erythropoietic activity is adversely affected and the no. of the circulating red corpuscles are reduced. The granulocytopoietic tissues are also depressed. The lymphopoietic system is not substantially altered. 32 references. A. H. Krappe

The metabolism of nucleoproteins in lead poisoning. G. Michetti and F. Molfino. *Rass. med. ind.* 10, 562–72 (1939).—An outline of past observations on lead poisoning is followed by original research on 10 cases with clinical data (table). They show a pronounced tendency to uricacidemia as a result of recent poisoning, becoming more acute in proportion as the poisoning tends to become chronic. No connection was seen between the degree of uricacidemia and kidney function, and no such connection is likely to exist in cases of recent lead poisoning. 25 references. A. H. Krappe

Significance of nicotine in forensic biology. Bonne. *Deut. Z. ges. gerichtl. Med.* 30, 308–12(1939).—The smoking of strong cigars and cigarets can produce degeneration of the cardiac nerves and brain cells resulting in fatal cerebral paralysis, and disorders of the endocrine glands, liver and sex glands. Frances Krasnow

Histo-toxicological investigations of 3,5-dinitrophenol. Antonio Risi. *Z. Biol.* 99, 431–42(1939).—The min. subcutaneous lethal dose of 3,5-dinitrophenol for guinea pigs is 0.05 g./kg. body wt. Repeated small, sublethal doses had no cumulative effect. The symptoms of poisoning are rapid breathing, tachycardia, raised temp., flaccid paralysis of all limbs, particularly the hind legs, deeply colored urine and hardening of the eyes. These symptoms last 2 hrs., after which death occurs because of cardiac failure. The most important histological changes appear as deep protoplasmic and nuclear degenerations in the liver and kidneys. Frances Krasnow

The nervous and muscular effect of strophanthin. H. Reichel. *Z. Biol.* 99, 590–5(1939).—Strophanthin apparently increased the contraction of the artificially stimulated heart, having a purely muscular effect. On the normally beating heart it had a neg. inotropic, chronotropic and dromotropic influence. On the fatigued normally beating heart, there was a pos. inotropic, but a neg. chronotropic and dromotropic effect. F. Krasnow

Methemoglobin as the principal abnormal pigment in the blood of human subjects showing cyanosis from sulfanilamide. Wm. B. Wendel, Nannette M. Wendel and W. W. Cox. *J. Biol. Chem.* 131, 177–85(1939); cf. *C. A.* 33, 5481[6].—Spectrophotometric and gasometric analyses of fully oxygenated blood from cyanotic patients who had been given sulfanilamide indicate that the abnormal color of the blood was for the most part due to methemoglobin rather than to colored derivs. of sulfanilamide. A. P. Lothrop

Treatment of schizophrenia with glandular extracts. Siegfried Fischer. *Arch. Neurol. Psychiat.* 42, 644–51 (1939).—Exts. contg. anterior pituitary-like substances from the urine of pregnant women have given good therapeutic results in the treatment of schizophrenic patients. Prepns. from the anterior lobe itself were useless. G. H. W. Lucas

Cerebral changes in fatal cases following treatment with barbital, soluble barbital U. S. P., insulin and metrazole. George B. Hassin. *Arch. Neurol. Psychiat.* 42, 679–89 (1939).—Examn. of the brains of persons dying from barbiturate poisoning or from insulin or metrazole shock show morphologic changes in the ganglion cells of the brain, often assocd. with neuronophagia. These changes appear to be most evident in the olivary bodies, but are not specific for these poisons. A more serious evidence of damage is found in a distention of subarachnoid and cerebral tissue spaces. G. H. W. Lucas

Histopathologic changes in the brain after experimental injection of metrazole. Erich Liebert and Arthur Weil. *Arch. Neurol. Psychiat.* 42, 690–9(1939).—In the brains of rabbits injection of large doses of metrazole (a total of 700 mg. in several injections) produced a more or less severe shrinking of both cytoplasm and nuclei of neurons, also hyperplasia and hypertrophy of the different types of glia cells. The pathol. effect was most pronounced in the striatum and hippocampus. G. H. W. Lucas

Mode of action of brilliant Vital Red in epilepsy. Robert B. Aird. *Arch. Neurol. Psychiat.* 42, 700–23(1939).—A protecting action of Vital Red has been demonstrated in epilepties and in animals where convulsions were produced experimentally. It is believed that the endothelium concerned with the formation of cerebrospinal fluid forms an effective protective barrier to the central nervous system and that brilliant Vital Red decreases the permeability of this barrier to convulsant poisons, such as cocaine and picrotoxin. The protective action in epilepsy may be due to a decreased permeability of the barrier to "convulsant toxins" which may contribute to the production of epileptic convulsions. G. H. W. Lucas

Blood lipoids in dementia praecox and during insulin-shock therapy. M. Gerundo and W. W. Corwin. *J. Nervous Mental Disease* 90, 464–82(1939).—In cases which have improved after insulin-shock therapy, the ratio between phospholipins and cholesterol tends to become higher and approach the normal. G. H. W. Lucas

Sulfanilamide: its mode of action and side effects. Chester S. Keefer. *Med. Clinics N. America* 23, 1133–48 (1939).—A review. G. H. W. Lucas

Pharmacologic study of the bronchial musculature. I. Technical contribution to perfusion of the isolated guinea-pig lungs. R. Benelli. *Arch. sci. biol.* (Italy) 24, 249–66 (1939).—Perfusion app. is described. **II. The action of *p*-methylaminoethanolphenol (Sympatol) on the bronchial musculature.** *Ibid.* 267–80.—Sympatol, in the perfused isolated guinea-pig lung, in general has an adrenaline-like action and does not present the qual. characteristic differences that have been demonstrated in the cardiovascular app. The doses employed were 60–200 times those of adrenaline. It is less toxic and its action lasts longer than that of adrenaline. P. F. Metildi

The phospholipide content of the liver during the lipotropic action of choline. F. Cedrangolo and V. Baccari. *Arch. sci. biol.* (Italy) 24, 311–18(1938).—The administration of choline to dogs with fatty liver from phlorizin and almost devoid of glycogen produces a distinct diminution of the phospolipide contents (21.32%). Coincident with this, the balance between glycerol fat acids which disappear and glycogen that is formed makes one suppose that at least part of the glycogen is derived from the acid quota of the glyceride which disappeared. Conclusion: The phospholipides do not represent an intermediate stage in the transformation of glyceride lipides in glucides. P. F. Metildi

The influence of choline on ketonuria. R. Conte-Marotta. *Arch. sci. biol.* (Italy) 24, 396–8(1938).—Choline fed to rats made ketonuric by fasting and phlorizin slightly diminished the ketonuria. Parallel to this

there was a diminution of fat and increase in glycogen in the liver. P. F. Metildi

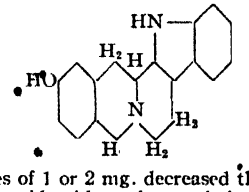
The toxicity of metallic arsenic in relation to variations in alkaline reserve. Alberto Cannavà. *Arch. sci. biol.* (Italy) **24**, 442–51(1938).—Metallic As absolutely free of oxidation products is toxic subcutaneously. The alk. reserve is lowered in normal animals and in those in alkalosis and acidosis. The toxicity is less in animals in acidosis than in those in alkalosis. P. F. Metildi

The metabolism of sorbitol in the organism. R. Porrati and P. Rowinski. *Arch. sci. biol.* (Italy) **24**, 487–99 (1938).—The ingestion of sorbitol increases the R. Q and the consumption of O_2 above the basal level. The effect is similar in 4 hrs. to that of equal doses of glucose, so that it is not probable that sorbitol is changed to glucose. The reducing power of the blood is unchanged. Sorbitol is not completely utilized. A part of it is excreted in the urine for a few hrs. after ingestion. P. F. Metildi

Pharmacological investigations on β-phenylisopropylamine. R. Marri and G. Franceschini. *Arch. sci. biol.* (Italy) 25, 7–37(1939).—The minimal lethal dose of β-phenylisopropylamine given subcutaneously is 1 mg./g. of frog (*Rana esculenta*), 0.28 g./kg. body wt. for the mouse, and 0.168 g./kg. body wt. for the guinea pig. It has a neg. inotropic and chronotropic action on the frog heart, isolated or *in situ*, and on the isolated guinea-pig heart; this is still seen after vagal paralysis. It augments the tone and sometimes the amplitude of contraction of the isolated duodenum and ileum of the mouse, guinea pig or rabbit. These actions are not dependent on stimulation of the parasympathetic. It produces a marked increase in tone and contractions of the isolated uterus of the guinea pig. In isolated lungs of guinea pigs and those of the cat *in situ* it exercises a weak and inconst. dilatation. No action on the urinary bladder of the cat was observed *in situ*. There is strong vasoconstriction in the isolated ear of the rabbit. In the cat and dog it produces hypertension, in the rabbit hypotension. Successive doses produce dissimilar effects. In both narcotized and nonnarcotized animals it produces increase in amplitude and frequency of resp. movements when given intravenously or by inhalation. P. F. M.

The metabolism of acetic acid. I. The action of acetic acid on alkali reserve compared with that of other acids of metabolic importance. A. Ferrante. *Arch. sci. biol.* (Italy) 25, 38–50(1939).—The behavior of the alk. reserve of the blood after intravenous injection of this acid was compared with the effect of equiv. amts. of other acids (lactic, pyruvic and HCl). With HCl the alk. reserve is lowered constantly and considerably. Pyruvic acid has a slight and transient effect. Lactic acid lowers it significantly and the rate of recovery decreases with lapse of time. AcOH lowers it very little, but the decrease is persistent. AcOH is assumed to be unoxidizable when present in small amts. in the blood. P. F. Metildi

Behavior of cobalt, nickel and copper introduced intravenously in finely divided state. I. Histological investigations and determination of the amount in organs. Alberto Cannavà. *Arch. sci. biol.* (Italy) 25, 309–40 (1939).—Co and Ni produce slight anatomical changes in rabbits while Cu in equal doses is much more harmful. The metals are found for the most part in the lungs and for a short time, after which they are excreted. Co and Ni leave no appreciable alterations. **II. Elimination and action on leucopoiesis.** *Ibid.* 341–59.—Co is excreted principally by the kidneys; Ni and Cu are excreted mostly through the intestines. There is a marked neutrophil leucocytosis after introduction of the metals. **III. Powders of silver, aluminum and zinc. Histological investigations and the action on leucocytes.** *Ibid.* 360–71.—The dosage used was 0.002–0.010 g./kg. in rabbits. No appreciable disturbance was noted with Ag and Zn, but Al occasionally produced death by pulmonary embolism. The lungs showed granulomatous focal lesions, congestion and small hemorrhagic zones. Slight degenerative lesions especially with Ag were evident in the liver and kidneys. Slight leucocytosis was produced by Ag, while the others produced little or no change. P. F. Metildi



Factors modifying the activity of certain local anesthetics. Alma Salis. *Arch. intern. pharmacodynamie* (Italy) **61**, 271–88(1939).—The cornea of the rabbit was used to measure the topical activity of 0.5% cocaine and 1% procaine. The solns. with a low pH were more stable while those with a high pH were more active. Sterilization of the soln. brings about acidification. At 40° and 50° all the samples became inactive except cocaine with a high pH which kept part of its anesthetic action. The hypo- and hypertonic solns. are more active than the isotonic ones. P. F. Metildi

Pharmacology of strontium. Its actions on circulation and respiration. A. Boriani. *Arch. intern. pharmacodynamie* (Italy) **61**, 289–318(1939); cf. *C. A.* **33**, 5509[8].

In rabbits and dogs the actions of $SrCl_2$ are: Small doses produce hypertension almost exclusively of a cardiac type; in small part this is due to sympathetic stimulation and in large part to muscular action. In large doses it produces cardiac inhibition through a paralysis of the intrinsic rhythmic centers of the heart. With small doses respiratory excitation occurs; with moderated doses it often in the rabbit and not in the dog produces brief apnea from direct action on the respiratory center. With large doses longer apnea is produced. With very large doses there is vasoconstriction through the sympathetic. When these large doses are given intravenously death occurs with cardiac arrest. It is impossible to det. the exact lethal dose since $SrCl_2$ diffuses rapidly. **II. The action on bronchial motility.** *Ibid.* **62**, 1–29.—$SrCl_2$ used on guinea pigs produced a bronchial constriction. There was also a synergistic action with histamine. Atropine has no effect on this action. $SrCl_2$ does not modify the action of adrenaline, while adrenaline prevents the bronchoconstriction of $SrCl_2$. $SrCl_2$ and $BaCl_2$ reënforce their reciprocal actions. $SrCl_2$ antagonized the bronchodilating action of Mg. P. F. Metildi

The source of the energy used by phlorizinized rats in defense against decreased temperature. G. Sarzana and F. Fazio. *Biochim. terap. sper.* **121**, 297–303(1939).—Rats poisoned with high doses of phlorizin and kept at 3.5 to 4° showed a drop in body temp. from 2 to 4°, approx. the same as in normal rats. The av. O consumption per kg. per hr. was in normal rats 4.96 (at normal temp. 1.8 to 2) g. and 4.99 in the phlorizinized rats. The R. Q. was 0.85 in normal and 0.76 in the test animals. Conclusion: Phlorizin-poisoned rats exposed to low temp. are able to utilize material poor in carbohydrates. A. E. Meyer

A new synthetic sympatheticolytic substance belonging to a chemical group of natural sympatheticolytic substances. Raymond-Hamet. *Bull. acad. méd.* **121**, 274–81(1939). An indole compd. resembling in configuration certain yohimbine derivs. of the following structure was

studied. Doses of 1 or 2 mg. decreased the pressor effect of adrenaline considerably and turned the decrease in the vol. of the kidney by adrenaline into an increase in vol. After 5 mg. the pressor effect of adrenaline was insignificant and was immediately followed by a drop to below the initial pressure. This reversed effect of adrenaline was abolished by repeated application of the substance leading to approx. normal pressor response. The substance has a strong vasodilator effect. A. E. Meyer

Chemotherapy of trachoma with a glucose derivative of 4,4′-diaminodiphenylsulfone. The action on pannus. Et. Burnet, E. Cuénod and R. Nataf. *Bull. acad. méd.* **121**, 317–24(1939).—The substance is sol. in H_2O and was used in a 7% soln. filtered through a Chamberland filter. Injections were made below the superior and inferior palpebral as well as the bulbar conjunctiva. The treatment had little success on the conjunctiva, but was quite effica-

cious on the cornea. The visual power was much improved in some cases. This compd. is more effective than the remedies used hitherto ($CuSO_4$, PhOH, HgOCN). A. E. Meyer

The effect of zinc in various conditions of the uterus and the ovaries. Henri Vignes. *Bull. acad. méd.* **121**, 412–15(1939).—In view of the fact that Zn alters the action of some hormones, usually by increasing their effect, the influence of Zn medication in utero-ovarian disturbances was studied. Zn acetate or valerianate was given in doses of 100 mg. daily. The 75 cases of menstrual disorders, menorrhagia and amenorrhea reported showed a high incidence of improvement. One of 2 cases of dysmenorrhea improved. Cessation of treatment was usually followed by relapse. Five cases of abortion were successfully treated but in combination with other treatment. Among 22 cases of sterility 7 were brought to pregnancy. A. E. Meyer

Serotherapy and poisoning with scorpion venom. Etienne Sergent. *Presse méd.* **47**, 1037(1939).—Coma may occur 2–24 hrs. after the sting. Serum treatment was lifesaving in 81% of the cases. A. E. Meyer

Histidine in the treatment of gastroduodenal ulcer. R. Escudero. *Semana méd.* **1939, II**, 680–9.—A review. A. E. Meyer

Action of insulin on the chronaxie of the foot of the snail. Raymond Cahen. *Compt. rend.* **209**, 447–8 (1939).—Insulin, in relation to its hypoglucemic action, stimulates the isolated heart and depresses the isolated intestines. Its effect on the isolated foot muscle of the snail was noted by measuring the chronaxie. Insulin increases the chronaxie, but the effect is not persistent, in spite of the maintenance of the prepn. in contact with hormone. The rheobase was increased equally with the chronaxie. There is spontaneous cessation of the action of insulin after prolonged contact. It diminishes after 35 to 50 min., and tends to regain its initial value after 45 to 65 min. It is not due to a change in insulin, as a new amt. of insulin added to the old again raises the chronaxie. In its effect on muscle, insulin acts as a potential poison. Dorothy A. Meyer

The hematological disturbances in benzene poisoning. F. Mignolet. *Sang* **13**, 268(1939).—A thrombocytopenia with prolongation of coagulation time is an alarming sign in benzene poisoning, the anemias of which are usually of the hyperchromic aplastic type. I. A. Mirsky

Sulfanilamide and meningitis. S. W. Sappington and Grant O. Favorite. *Ann. Internal Med.* **13**, 576–97 (1939).- A review with 60 references. J. T. Myers

Observations upon the experimental and clinical use of sulfapyridine. III. The mechanism of recovery from pneumococcal pneumonia in patients treated with sulfapyridine. W. Barry Wood, Jr., and Perrin H. Long. *Ann. Internal Med.* **13**, 612–17(1939); cf. *C. A.* **33**, 9406⁶.—Type-specific antibodies play an important part in recovery from pneumococcal pneumonia after treatment with sulfapyridine, but they do not appear for several days after the temp. has fallen to normal. Hence relapses will occur if sulfapyridine is discontinued too soon. 17 references. John T. Myers

Observations on toxicity and clinical value of strophanthin. W. A. Brahms, J. S. Golden, A. Sandra and J. Kaplan. *Ann. Internal Med.* **13**, 618–28(1939).—Single intravenous injections of 0.5–0.75 mg. of strophanthin K in normal persons failed to produce significant clinical or electrocardiographic evidence of toxicity. In patients with severe cardiac failure, 0.3–0.5 mg. was not toxic. Daily injections of 0.3 mg. for 24 days were not toxic. Strophanthin is preferable to digitalis in the routine treatment of cardiac failure. 30 references. John T. Myers

Cyanosis and anemia in chronic acetanilide poisoning. P. Meulengracht and I. Lundsteen. *Folia Haematol.* **63**, 89–99(1939).—In chronic acetanilide poisoning there is a characteristic grayish blue-violet cyanosis. It is due to *p*-aminophenol derivs. and not to methemoglobin. An anemia develops later and may become very severe. John T. Myers

The toxicity of lauryl thiocyanate and *N*-butyl-carbitol-thiocyanate (Lethane 384). G. R. Cameron and Cecile R. Doniger. *J. Path. Bact.* **49**, 363–79(1939).—Undild. lauryl thiocyanate produces a severe local skin reaction. It is fatal to mice, rats, guinea pigs and rabbits only when introduced into the body in fairly large amts. Death is due to respiratory failure probably of medullary origin. No characteristic effects are produced on the blood or in the organs. Dilns. such as are used in field work have no ill effects. Lethane 384 produces only a slight local skin reaction but is fatal to animals in much smaller quantities than is lauryl thiocyanate. Otherwise it produces the same effects. John T. Myers

The mode of action of prontosil. Johann Hammerschmidt. *Zentr. Bakt., Parasitenk.*, I Abt., Orig. **144**, 447–9(1939).—When streptococcal lesions are produced in mice by the injection of agar cultures of hemolytic strains, treatment with prontosil causes the formation of a wall of leucocytes about the lesion which prevents the passage of streptococci. No increased phagocytosis occurs. Protective humoral substances, especially antiaggressins, are also produced. John T. Myers

Analeptic action of Pervitin (β-methylamino-α-phenylpropane). C. Püllen. *Munch. med. Wochschr.* **86**, 1001–4(1939).—Pervitin, 6–9 mg., given by mouth exerted antifatigue effects, and was successful in treating alc. intoxication. Increase in arterial pressure occurred when 6 mg. was used. Maurice M. Rath

Toxicity of procaine. L. Riedi. *Schweiz. med. Wochschr.* **69**, 595–6(1939). Severe syncope and respiratory arrest occurred in a healthy girl after 3 cc. of a soln. contg. 0.5% procaine and 1 mg. adrenaline were injected into the soft palate. Maurice M. Rath

Dihydrotachysterol and thallium. A. Bushke and Wladimur Konheim. *Schweiz. med. Wochschr.* **69**, 702–3 (1939).—Tl alone and Tl plus dihydrotachysterol (I) were given to sep. groups of rats. At the end of several months, the animals receiving only Tl appeared stunted in growth and weighed on the av. 85 g. as compared to 250 g. for those receiving I. Rachitic changes and inhibition of growth caused by Tl were counteracted by I. The function of the hypophysis, thyroid, thymus, sex and parathyroid glands is impaired by Tl. I promotes the function of the parathyroid gland as in tetany and tetany cataract. Maurice M. Rath

The toxicity of poisons applied jointly. C. I. Bliss. *Ann. Applied Biol.* **26**, 585–615(1939). Methods for the statistical analysis of toxicity data from poisons administered jointly to animals are described. Types of joint action recognized are: independent joint action; similar joint action; synergistic action. Each is discussed and the statistical treatment is illustrated by an example from the entomological literature. C. H. Richardson

Functional alterations of organs, especially of spleen and parathyroid, by injections of calcium. Ariyoshi Mori. *Chosen Med. Assoc.* **29**, 594–643(German abstr. 38–40) (1939).—An injection of $CaCl_2$ soln. into the rabbit produces diphasic changes, in serum Ca (**A**), and blood platelets (**B**), an increase and subsequent decrease below normal of **A**, and initial decrease, and subsequent rise of **B**. After Ca injection, there appear in the blood 2 substances, one of which has the power to decrease **A**, and the other to diminish **B**, the former being a saponifiable lipide, sol. in org. solvents and insol. in H_2O; and the latter being a protein, insol. in org. solvents, and sol. in H_2O. The Ca-decreasing substance is identical with a substance found in parathyroid, but not parathyroid hormone proper; and the blood-platelet-reducing substance is identical with a substance found in the spleen, but not identical with the splenic hormone proper. Both substances appear in greater amts. during the neg. phase. The functional alteration of the spleen and parathyroid must be considered for the understanding of the effect of Ca injection. S. Tashiro

Relation between phenol and autolysis of various organs of animals poisoned with chloroform, carbon tetrachloride and phosphorus. D. Yanagihara. *J. Chosen Med. Assoc.* **29**, 651–68(German abstr. 41)(1939).—When rabbits are poisoned with $CHCl_3$, CCl_4 or P, the autolysis of liver

and kidney is accelerated, and at the same time blood PhOH increases. The retention of PhOH in cholemia might be explained by these facts. S. Tashiro

Relation between phenol and autolysis of various organs of animals poisoned with cantharidin, uranium and sublimate. D. Yanagihara. *J. Chosen Med. Assoc.* 29, 489–506(German abstr. 31)(1939).—The isolated tissues of rabbits poisoned with cantharidin, U or $HgCl_2$ undergo autolysis much faster than those of the normal, and produce PhOH. This PhOH formation *in vitro* is particularly pronounced in liver and kidney after U poisoning. S. Tashiro

Pharmacological action of thebaine. Kiko Haku. *J. Chosen Med. Assoc.* 29, 860–8(German abstr. 47–9)(1939).

Pharmacological action of morphine. I. The effect on toad heart. *Ibid.* 869–80(German abstr. 49–50).—Judging from their effect on the toad heart, the actions of thebaine and morphine are similar in respect to their behavior against atropine, on vagus and sympathetic nerves, acetylcholine and nicotine. But the actions of adrenaline and $BaCl_2$ on the heart treated by these 2 drugs are different, as well as their effect on perfusion on Nissl bodies of intracardial nerves. The inhibiting action of thebaine on toad heart is due to paralysis of cardiac muscle, that of morphine to action on intracardiac ganglion cells. S. Tashiro

The influence of histotoxin upon the hypoglucemia produced by insulin. Seikei Ri and Hukusei Syu. *J. Chosen Med. Assoc.* 29, 1009–23(English abstr. 64–5)(1939).—An injection of 10 cc. per kg. body wt. of histotoxin (Yasuo and Uehara) into rabbits produces no change in blood sugar, but that of a mixt. of histotoxin and insulin greatly reduces the hypoglucemic effect of insulin. If histotoxin is injected first and then insulin, hypoglucemia results as if the latter is injected alone. If insulin is injected first and histotoxin next, there is no effect unless the latter is injected before the max. hypoglucemia is reached. Boiled egg albumin, glutathione and histamine have a similar effect, but not as strong as that of histotoxin. S. Tashiro

Pharmacological action of morphines. II. The effect of morphine, digitoxins and other autonomic nerve poisons on the hearts of chronically morphinized toads. Kiko Haku. *J. Chosen Med. Assoc.* 29, 1049–60(German abstr. 67–8)(1939).—The perfusion of various autonomic poisons through the hearts of toads that had received morphine (0.07–0.15 g. per 100 g. body wt.) during 3–4 weeks previously shows that such a heart is less susceptible to morphine, nicotine, acetylcholine and adrenaline, but reacts like a normal heart to ergotamine, yohimbine and digitoxin. S. Tashiro

Pharmacological studies with Japanese limulus heart. I. The method of perfusion and the results with various drugs. Kiko Haku. *J. Chosen Med. Assoc.* 29, 1061–83 (German abstr. 68–71)(1939).—The method of perfusion of limulus heart is illustrated with a figure and the results of the perfusion with KCl, adrenaline, acetylcholine, atropine, nicotine, cocaine, papaverine and the effects of glucose concn., temp., pH and viscosity are given. **II. Autonomic contraction of limulus heart.** *Ibid.* 1084–111 (German abstr. 71–3)(1939).—Pharmacol. studies show that 2 sets of nerves, mutually antagonistic, control the heart. The peristaltic movement of autonomic heart beat is also analyzed with the use of drugs. S. Tashiro

Pharmacological study on the uterus of rabbits after repeated injections of uterine extract. Hideo Naozuka. *J. Chosen Med. Assoc.* 29, 1276–306(German abstr. 84–6)(1939).—Uterine ext. is very toxic, 0.13–0.6 cc. 25% Lock soln. ext. of the organ per kg. body wt. killing the rabbits when intravenously injected. Subcutaneous injection is apparently harmless. The uterus of the rabbits to which 0.5 cc. has been thus injected every third day for 10–12 times shows the normal reaction against adrenaline and pilocarpine, but is less susceptible to pituitrin, papaverine and $BaCl_2$. Ovaries and uterus of these animals decrease in wt. and size, but do not show any histological change; they are not fertile. The control injections of muscle exts. do not show such changes. S. Tashiro

Histological changes in parathyroid and thyroid glands in experimental uranium nephritis. Nitizen In and Gentetu Ryo. *J. Chosen Med. Assoc.* 29, 1459–65(English abstr. 94–5)(1939).—In U nephritis the parathyroid undergoes marked changes, showing general engorgement of blood vessels, cloudy swelling of parenchymal cells, vacuolization, karyorrhexis, fatty degeneration and proliferation of interstitial tissue. Thyroid gland shows a slight decrease in colloids, and a little congestion. S. Tashiro

"Histotoxin," especially its action on myxosarcoma of fowl. Yutaka Uehara. *J. Chosen Med. Assoc.* 29, 1601–36(German abstr. 102–6)(1939).—The perfusion fluid of the tissues (toad skin and stomach) injured by acids contains a histotoxin (Osawa) which accelerates the growth of cultures of fibroblasts and osteoblasts and myxosarcoma of fowl. Repeated injections of histotoxin in myxosarcomatous fowl not only prolongs the survival period of the fowl but also cures the disease. The fowl thus cured cannot be reinoculated. S. Tashiro

Toxicity of "Thu Hung," a lip pomade used by Northern Manchurian maidens. Suguru Syozima, Kyotaro Matuoka, Tadasi Ikarasi and Eiiti Saito. *J. Oriental Med.* 30, 567–75(German abstr. 172)(1939).—Various pathol. symptoms produced in rats, dogs, rabbits and guinea pigs by oral administration of this org. dye used by young girls in Northern Manchuria are reported. Whether or not this dye is the cause of "Kozau disease" prevalent in these districts has not yet been detd. S. Tashiro

Influence of hibernation on virulence of the virus of lymphogranuloma inguinale. Tosiwo Akiyama. *J. Oriental Med.* 30, 617–38(English abstr. 177–8)(1939).—Intracranial injection of the virus into the normal Manchurian ground squirrel produces symptoms of typical meningo-encephalities in 5–7 days. With hibernating animals, a similar injection does not cause the symptoms if the animal is allowed to hibernate more than 20 days after the injection and then kept awake. S. Tashiro

A new method of treatment of alkaloid addicts by tetrodotoxin. Nai Shi Hsiang. *J. Oriental Med.* 30, 639–47(German abstr. 179)(1939).—From 1 to 2 cc. of tetrodotoxin ($C_{10}H_{32}O_{16}$) mixed in 20 cc. 20% glucose soln. is given intravenously or orally to 18 subjects of opium and heroine habits, the no. of dosages depending upon the severity of the symptoms, and oral treatment requiring a greater amt. of the drug. Detailed data are given as to various symptoms before and after the treatment, confirming his previous success with 1500 patients. S. Tashiro

The effect of continuous feeding of inorganic iron. I. Ferrous carbonate and reduced iron on blood-iron content and blood pictures. Nobumasa Hayasi. *J. Oriental Med.* 30, 651–91 (English abstr. 181)(1939).—The av. blood-iron contents of normal rabbits vary between 0.063 and 0.097 mg. per cc. when the blood counts are made every other day. When 0.6 g. $FeCO_3$ or 0.3 g. reduced Fe is given daily for as long as 127 days, there is a rise noticeable within 3 days, and then a great fluctuation, sometimes 2–3 times as great, the other time to about normal level. There's no change in the blood picture, except a slight rise in eosinophiles. **II. Decrease of high blood-iron content after the discontinuance of ferrous carbonate feeding.** *Ibid.* 863–73 (English abstr. 257).—The blood iron content becomes normal in 14–16 days after the discontinuance of $FeCO_3$ feeding, regardless of how long the carbonate was fed. **III. Urinary and fecal iron content.** *Ibid.* 1079–99 (English abstr. 279).—A daily urinary excretion of iron by the normal rabbit varies 0–0.1086 mg., and the iron content of feces, 0.64–1.6231 mg. per 1 g. feces. When 0.6 g. $FeCO_3$ is fed daily, urinary iron begins to rise soon after the onset of the feeding, and that of feces rises as much as 46 mg. per g. Fecal iron does not return to normal within 14 days after the discontinuance of iron feeding. S. Tashiro

The effect of chronic opium and narcotic habits on the female genital organs. I. Statistical studies of gynecological disorders among opium and heroine addicts. T. R.

Ko. *J. Oriental Med.* 30, 875–90 (German abstr. 258) (1939). II. **The effect of administration of total opium alkaloid (raw opium) on the sex cycle of female mice.** *Ibid.* 891–903 (German abstr. 259–60). III. **The fertility of female mice.** *Ibid.* 1107–22 (German abstr. 281). IV. **The reactions of isolated uterus of rabbits poisoned with opium against various drugs.** *Ibid.* 1195–217 (German abstr. 289). S. Tashiro 1

The tetany lens under the influence of AT10 (dihydrotachysterol). Walter Rauh. *Arch. Ophthalmol.* (Graefe's) 140, 334–53(1939).—Expts. with parathyroidectomized rats indicate that the early administration of AT10 frequently prevents, or at least attenuates, cataract formation. Frank Urban 2

The content of sulfanilamidopyridine (M. and B. 693) in the ocular fluid of rabbits after administration of the drug. J. Pinkhof. *Z. Augenheilk. (Ophthalmologica)* 97, 356–63(1939).—After oral administration of M. and B. 693 to rabbits in doses of 0.1 g. per kg., the drug was found in the ocular fluids in concns. approaching those in blood. Local application in the conjunctival sac did not result in intraocular resorption. The diffusion into the ocular fluids is rapid. The concns. found may have antibacterial action. Frank Urban 3

The relation of blood pressure and concentration in serum of potassium, calcium and magnesium. Hebbel E. Hoff, Paul K. Smith and Alexander W. Winkler. *Am. J. Physiol.* 127, 722–30(1939); cf. *C. A.* 33, 6963[7].—K, Ca and Mg salts were injected intravenously in dogs and cats at a slow uniform rate until death occurred. The blood pressure showed only minor changes during the K and Ca injections until terminal cardiac failure supervened. There was then an abrupt fall to zero. An immediate fall in blood pressure appeared when Mg was injected. Mg provoked an immediate rise in skin temp., while K and Ca did not. Mg is a powerful vasodilator while K and Ca, similarly given, are without marked effect. The vasodilator effect of Mg is in part due to a change of the concn. of circulating Mg and in part to the presence of higher concn. E. D. Walter 4

The relation of lipocaic to the blood and liver lipides of depancreatized dogs. Lester R. Dragstedt, Paul B. Donovan, Dwight E. Clark, W. Carter Goodpasture and C. Vermeulen. *Am. J. Physiol.* 127, 755–60(1939).—The total serum lipides of insulin-treated depancreatized dogs rise somewhat above normal during the 1st week after pancreatectomy and then gradually decline, reaching a level approx. half of the normal in 5 or 6 weeks. This hypolipemia is coincident with the development of marked fatty infiltration of the liver and the other signs of lipocaic deficiency. The oral administration of lipocaic corrects this hypolipemia within a week and maintains the blood fat at the normal level. E. D. Walter 6 7

The effect of cortin and desoxycorticosterone acetate on the ability of the adrenalectomized rat to inactivate histamine. Bram Rose. *Am. J. Physiol.* 127, 780–4 (1939).—The ability of the adrenalectomized rat maintained on 0.85% saline to inactivate histamine may be restored by the administration of adrenal cortex ext. or of desoxycorticosterone acetate. The maintenance dose of cortin for a rat is wholly inadequate to restore the ability of the animal to inactivate histamine. E. D. Walter 8

A comparative study of the effect of the interaction of ions, drugs and electrical stimulation as indicated by contraction of unstriated muscle. Inderjit Singh. *J. Physiol.* 96, 367–84(1939); cf. *C. A.* 33, 6968[2]. E. D. Walter

The effect of monosaccharides on water absorption from the subarachnoid space. T. H. B. Bedford. *J. Physiol.* 96, 392–6(1939); cf. *C. A.* 32, 9297[9].—Isotonic solns. of glucose, xylose and mannose were without influence on absorption when introduced into the subarachnoid space for 1 hr. Solns. twice the isotonic concn. caused a marked reduction in absorption after 30 min. These sugars have a similar action on water absorption and they are in all probability absorbed by a common process. No evidence was obtained of a specific absorption of glucose such as occurs in the intestine. E. D. Walter 9

The administration of large doses of ascorbic acid and of methionine to the cystinuric. James C. Andrews and Kathleen C. Andrews. *J. Elisha Mitchell Sci. Soc.* 55, 203–7(1939).—A comparison was made of the effect of diuresis, of methionine administration and of ascorbic acid administration on the cystine output of a cystinuric subject. Doses of ascorbic acid up to 6.0 g. per day, with controlled H_2O intake, produced an increase of about 16% over the av. normal figure while doses of methionine up to 5.0 g. caused an increase of 30–35%. This latter increase is greater than was obtained 3 yrs. previously with the same subject when preadolescent. Water drinking, approx. quadrupling the urine vol., increased the cystine output by nearly 50% by the direct Sullivan method (cf. *C. A.* 31, 425[4]) and nearly 70% by the $CuCl_2$ method. Colin W. Whittaker

The histological changes of liver produced by nicotine. J. Inoue. *Japan. Z. Mikrobiol. Path.* 32, 1356–66(1938).—The author found that atrophy and vacuolar degeneration of liver cells, passive hyperemia of blood vessels, and hyperplasia of connective tissues appeared in liver after the injection of nicotine into ear vein in rabbits. I. S. Yun

Further studies on the biological action of arsenite. IV. The spleno-hepatogenous development of anemia. Yanosuke Hiraoka. *J. Med. Coll. Keijo* 9, 75–93(1939); cf. *C. A.* 32, 4226[9].—For the development of anemia, due to arsenite, it is necessary that both liver and spleen be present in the body together, for the anemia does not occur after the loss of one, either by the removal of the spleen or by the cutting out of the liver by means of an Eck fistula. I. S. Yun

Origin of lenticular nucle softening by CO [coal-gas poisoning] (Breitenecker) 21. Soybean-oil foots—manuf. of lactation-promoting medicine and tests of its effects (Okano, *et al.*) 27. Relation between chem. constitution and local anesthetic activity (Lott, Christiansen) 10. Amidines and amide oximes with trypanocidal activity (Lamb, White) 10.

I—ZOÖLOGY

R. A. GORTNER

Relation between the hypophysis and gonads in various teleosteans and selaciens. J. H. Vivien. *Compt. rend. soc. biol.* 131, 1223–4(1939).—The implantation of fish hypophyses into various species of fish accelerated the production of eggs or sperm only when done a few days before the natural spawning period. At other seasons no effect was produced. L. E. Gilson

Antituberculous chemotherapy in insects. Action of sulfanilamide in Galleria mellonella caterpillars. V. Zernoff and L. Kotzovsky. *Compt. rend. soc. biol.* 131, 1250–2(1939); cf. *C. A.* 33, 8825[2].—Sulfanilamide injected simultaneously with tuberculous or paratuberculous organisms protected most of the caterpillars. Infected controls all died. L. E. Gilson

Blood ammonia of some invertebrates. Marcel Florkin and Hubert Renwart. *Compt. rend. soc. biol.* 131, 1274–6 (1939); cf. *C. A.* 32, 9303[2].—Snail blood contains 0.7–2.0 mg. % of NH_3 and the content does not increase when the drawn blood is exposed to air since adenosine deaminase is not present. Lobster blood contains 1.6–1.8 mg. % of NH_3. In the insect, hydrophila, the circulating blood contains no detectable NH_3 but some forms when the drawn blood is exposed to air, as with mammalian blood. L. E. Gilson

Presence of allantoic acid in the celomic fluid and corpuscles of Annelides and Sipunculida. Marcel Florkin and René Huguet. *Compt. rend. soc. biol.* 131, 1276–7 (1939).—Allantoic acid was present in the celomic fluid and corpuscles of the marine worms *Sipunculus nudus*, *Phascolosoma gouldii*, *Polycirrus eximinis* and *Arenicola*. It was not present in the celomic fluid of the holothurian, *Thyone briareus*, the blood of the mollusks *Arca inflata* and *Busycon canaliculatum*, or the blood of the crustaceans *Labinia emarginata* and *Limulus polyphemus*. L. E. Gilson

Extraction and crystallization of the pigment which gives the red color to the integument of certain mites of the genus Trombidium. Carmela Manunta. *Helv. Chim. Acta* **22**, 1154-5(1939).—Red mites (species not stated) were collected from the bark of trees The soft parts were removed and the remainder was extd. with Me_2CO. By the usual methods of sapon., solvent extn. and chromatographic adsorption on CaO the pigment was identified as astacin. L. E. Gilson

Disintegration of cellulose in the alimentary canal of Herbivora. Frank Baker. *Science Progress* **34**, 287-301 (1939).—A review of the biochem. changes produced in cellulose by the flora and fauna of the alimentary tract of herbivora. 55 references. Joseph S. Hepburn

Ammonia in invertebrate sea animals. II. Ammonia in the biological fluids of invertebrate sea animals and tunicates. E. Ya. Heiman (German summary). *J. Physiol. U. S. S. R.* **26**, 110-19(in German, 118-19)(1939); cf. *Ibid.* **20**, 846(1936); *C. A.* **29**, 845².—The ammonia N in the biol. fluids and blood of the bivalve mollusks *Pecten ponticus*, *Mytilus galloprovincialis* and *Ostrea taurica* is 0.026 and 0.107, 0.037 and 0.109, and 0.084 and 0.334 mg. %, resp., while biol. fluids of *Anodonta* sponges (*Renera* sp.), medusa (*Aurelia aurita*) and actinia (*Actinia equina*) contain 0.072, 0.108, 0.129 and 0.129 mg. %, resp. The crustacea *Eryphia spinofrons* and *Carcinus moenas* contain 0.353 and 0.295 mg % of Ammonia N in the blood, and the tunicate *Ascidiella* (*Phallusia*) *aspersa* Müllerei has 4.24 mg. % in the biol. fluids and 12.17 mg. % in the blood. S. A. Karjala

A new animal tetrasaccharide in the eggs of the vineyard snail (Helix pomatia), synthesized from 4-*d*-galactoside-*l*-glucosan (dilactose anhydride(1,6)). F. May and L. Stadelmann. *Z. Biol.* **99**, 462-76(1939).—Eggs of *Helix pomatia* contain a tetrasaccharide which is a dilactose anhydride(1,6), 4-*d*-galactoside-*l*-glucosan. It was isolated from the galactogen in the eggs by boiling with KOH and then pptg. the galactogen with alc. The galactogen of the filtrate was distd. off, the residue dissolved in water and repurified from the remaining galactogen Frances Krasnow

Ionic effects on selachian and teleostean hearts. Hans H. Meyer. *Z. Biol.* **99**, 633-44(1939).—Sea water had a pos. chronotropic as well as inotropic effect which varied with the season. The inotropic and chronotropic influence of Ca injection was dependent upon age and season. In large doses it was almost always injurious. Mg and K had a neg. inotropic and chronotropic effect. Ca injected after Mg was injurious to the selachian heart. With the teleostean heart injury brought about by an overdose of Ca was corrected by Mg.; Ca after Mg was not poisonous. Frances Krasnow

The effect of calcium, magnesium and potassium on the sequence of heart beats of Chrysaora hysoscella L. and Rhizostoma octopus L. Hans H. Meyer. *Z. Biol.* **99**, 645-7(1939).—Hearts of *C. hysoscella* L. and *R. octopus* L. are affected by Ca, K and Mg ions in essentially the same way as vertebrate hearts. Injections of sea water into *R. octopus* L. had a pos. inotropic and chronotropic influence. Frances Krasnow

The rhythm of the dorsal vessel in the fasting larvae of Bombyx mori. Antonio Balli. *Arch. sci. biol.* (Italy) **24**, 339-45(1938).—In the first few days the rhythm is increased; at the end it is decreased. P. F. Metildi

The metabolism of the egg and embryo in anuric amphibians. II. Oxygen consumption. Alberto Stefanelli. *Arch. sci. biol.* (Italy) **24**, 411-41(1938).—After fertilization and to the blastula stage there is a significant increase in O_2 consumption. There is a slight increase in the morula stage, but the increase becomes notable with the beginning of gastrulation up to the formation of the neural plate. From this stage on, the increase is less but after neuralization the consumption increases again to the end of embryonic life. P. F. Metildi

The relation between liver weight and body weight in Lacerta muralis Laur. Antonio Balli. *Arch. sci. biol.* (Italy) **24**, 517-25(1938).—In males, as the weight increases there is a diminution of the ratio liver/body; in females the opposite is true. P. F. Metildi

The chemical composition of the Molluscum contagiosum inclusion bodies. C. E. van Rooyen. *J. Path. Bact.* **49**, 345-9(1939).—The envelope is composed mainly of carbohydrates which are largely removed by preliminary digestion with fresh human saliva but not by boiled saliva. In microincineration the outer covering is burned off completely. The mineral residue is probably mainly derived from the elementary bodies, but some may come from the matrix in which they are embedded. John T. Myers

Growth and survival of Japanese beetle larvae reared in different media. Daniel Ludwig and Henry Fox. *Ann. Entomol. Soc. Am.* **31**, 545-56(1939).—Attempts to rear *Popillia japonica* larvae on molds derived from various plants, soil and peat were largely neg. Molds from the grasses, *Andropogon scoparius* and *A. glomeratus*, however, furnished sufficient food for complete growth and metamorphosis. Addn. of wheat or yeast to a medium increased larval growth. These effects are probably due to the presence of vitamins of the B complex. Yeast is not a complete food for the larvae; it must be supplemented by org. material from another source. C. H. R.

The metabolism of the corn-ear worm. II. Glycogen and moisture. L. P. Ditman and G. S. Weiland. *Ann. Entomol. Soc. Am.* **31**, 578-87(1938); cf. *C. A.* **32**, 8010⁵.—Differences in age of corn does not affect the amt. of glycogen stored at 30° by larvae of *Heliothis obsoleta*. At 21°, prepupae from larvae reared on milk-stage corn contain larger amts. of glycogen than those reared on dough-stage or milk-stage corn at 30°. Glycogen decreases from the time the larva ceases to feed until the adults emerge. At about 5°, the rate of glycogen decrease is greatly reduced in keeping with the slow rate of metabolism. Increase in water during the pupal stage is correlated with a decrease of glycogen; part of this water may be derived from the oxidation of glycogen. Larvae reared on milk-stage corn contain more water than those reared on dough-stage corn. C. H. Richardson

The effect of temperature upon the oxygen requirements of certain adult insects and insect eggs. Virgil N. Argo. *Ann. Entomol. Soc. Am.* **32**, 147-63(1939).—Overwintering males and females of the cluster fly (*Pollenia rudis*) increase their rate of O consumption with increase in temp. This rise in respiratory rate follows a composite curve made up of 2 successive exponential curves. The first curve, between −2.6° and 12.5°, shows a Q_{10} value of 5.50; for the second curve between 12.5° and 33.5° the Q_{10} value is 1.75. Above 33.5° the flies become restless and a purely basal metabolic relationship no longer exists. The large Q_{10} value at hibernating temps. is considered advantageous for the insect in its method of passing the winter. Adult female citrus mealybugs (*Pseudococcus citri*) also increase their rate of O consumption with increase of temp. From 2.25° to 27° Q_{10} is 2.95; above 27° the values for O consumption depart sharply from this curve, and up to 35° they appear to follow a catenary curve where Q_{10} is steadily reduced. A state of basal metabolism does not exist beyond 35°. Eggs of *Oncopeltus fasciatus*, 48-72 hrs. old show increasing O consumption with rise of temp. from 3° to 35°. Beyond 35°, a further increase results in decreased O consumption which becomes more pronounced as the temp. rises. A temp.-O-consumption curve seems to be catenary over the range studied; the van't Hoff theory is not followed. Above 47.5°, the eggs are rapidly killed. Conclusion: The temp.-respiration relationship cannot be expressed by any one curve or formula. It may be influenced by the state of development of the animal and the life habits to which it is adapted. C. H. Richardson

Nutritional studies of the confused flour beetle (Tribolium confusum Duval) and the bean beetle (Acanthoscelides obtectus Say). Shin Foon Chiu. *Ann. Entomol. Soc. Am.* **32**, 164-70(1939).—The nutritional requirements of *Tribolium* are satisfied by a diet of casein, corn starch, yeast, cottonseed oil and the Osborn-Mendel salt mixt. Sucrose is apparently not utilized and invertase is

possibly absent from the intestine. Some factors besides vitamin B_1 seem to be required; but vitamins A and D, and the Et_2O-sol. material from yeast are not necessary. *Acanthoscelides* requires for growth and development a substance found in the Et_2O ext. of kidney beans. Cholesterol can be substituted for fat, but development of the insect is retarded. C. H. Richardson

Digestive enzymes of the larva of the cattle grub Hypoderma lineatum (de Villiers). S. W. Simmons. *Ann. Entomol. Soc. Am.* **32**, 621-7(1939).—Lactase, maltase, invertase, glycogenase, lipase, rennin, trypsin and erepsin were found in the mid and hind intestines of this larva; none was found in the salivary glands or fore intestine. Glycogenase, lipase, trypsin and erepsin are apparently secreted by the larvae; the other enzymes are probably derived from bacteria in the intestine or from cystic exudate. Digestion occurs mainly in the mid intestine where proteins are broken down to amino acids, and fats and glycogen are digested. Small quantities of lipase and erepsin were extd. from the intestine; they may act on fats and peptones escaping from the mid intestine. All regions of the *Hypoderma* intestine are slightly acid except the hind intestine which is predominantly alk. The hemolymph gives a slightly acid reaction (pH 6.6 7.0). C. H. R.

Studies on the lipoprotein system of cyclostome and teleost fish. O. Callamand. *Bull. inst. océanograph.* No. 771, 12 pp.(1939).—The serum of cyclostomes (lamprey eel, *Petromyzon marinus*) and the teleost fish (carp, *Cyprinus carpio;* eel, *Anguilla vulgaris*) contain the 3 groups of lipoproteins described for the higher vertebrates by Macheboeuf (*C. A.* **31**, 5003[3]): (1) a fraction consisting of fats united with more labile complexes extd. by Et_2O or Et_2O cont. small amts. of alc., forming not more than 5% of the total fats; (2) fats extd. in the cold by Et_2O + alc., there being an optimal alc. concn. for max. extn.; (3) fats which are not extractible by Et_2O + alc. in the cold and upon hot extn. they are energetically denaturized. These 3 groups of lipoproteins are found in the serums of the fish studied. In the lamprey eel and carp the first 2 groups are less distinct and they intergrade; in *Anguilla*, however, the relation is like that in the higher vertebrates. The ratio of total fat to fats extd. in the cold does not have the significance in these fish of an albumin index (cf. Delage, Thesis Sci., Paris, 1939). The lipoproteins of these fish have a much higher osmotic pressure than that of the proteins which enter into their compn. Expts. showed that when *Anguilla* passes from fresh water to sea water there is a reduction of total serum fat and of fat extractable in the cold. Since most of the serum fat is lipoprotein material, and this diminishes with increased salinity of the water, it is believed the lipoproteins are important in the osmotic regulation of the blood to changes in salinity. C. H. Richardson

Variation in the molecular and chloride concentrations of the urine of stenohaline teleost fish as a function of variations in salinity of the external medium. Georgette Martret. *Bull. inst. océanograph.* No. 774, 39 pp.(1939); cf. *C. A.* **33**, 4681[8].—The carp (*Cyprinus carpio*) lives normally in fresh water ($\Delta = -0.02$), has a very dil. urine ($\Delta = -0.07$) and blood of $\Delta = -0.50$. Its urine is therefore slightly hypertonic in respect to the external medium. However, it can live in water contg. 17 g. NaCl per l. ($\Delta = -1.02$) if the adaptation is gradual. The kidneys exercise a very important function during adaptation and failure of them to eliminate NaCl leads to death. In saline media, the urine quickly becomes hypotonic; in solns. of Δ less than -0.90 (about 15 g. NaCl per l.) the fish become sick and the mol. concn. of the urine increases less rapidly than that of the blood or external medium, At death, in a medium of $\Delta = -1.04$, the urine has a hypotonicity of 0.14 in respect to the external medium and blood. Death seems to result from invasion of the blood by the external medium; the kidneys fail to continue elimination of NaCl. Expts. with the stenohaline, marine teleost, *Scorpaena porcus*, show that in sea water ($\Delta = -2.16$) the urine has Δ about -0.75, or 0.10 hypo tonic to the blood. The mol. concn. of the blood of this fish is remarkably low; and the hypertonicity of its urine is exceptional among marine teleosts. During adaptation to water less saline than sea water, the urine is very slowly dild. (from $\Delta = -0.75$ to -0.62 on passage from water of -2.16 to -0.54). Death seems to result not from progressive asphyxiation but rather from lesions of the brancheae. C. H. Richardson

Utilization of dextrose by Colpidium, Glaucoma, Chilomonas and Chlorogonium in bacteria-free cultures. John B. Loefer. *J. Expl. Zool.* **79**, 167-83(1938).—The ciliates, *Colpidium campylum* and *Glaucoma piriformis*, consumed dextrose, the former at a greater rate than the latter species. Unit consumption per hr. was greater than for trypanosomes. Acid formation was observed only in some cases when dextrose was used; alkali formation accompanied growth in the absence of sugar. The flagellates, *Chilomonas paramecium* and *Chlorogonium euchlorum*, did not utilize dextrose; but the presence of dextrose in the medium leads to better growth of ciliates and flagellates. The growth-pH relationships of *Chilomonas* and *Chlorogonium* were confirmed (Loefer, *C. A.* **30**, 5308[9]). C. H. Richardson

The rates of excretion of certain substances by the larvae of the meal worm, Tenebrio molitor L. Robert L. Patton and Roderick Craig. *J. Expl. Zool.* **81**, 437-57(1939).—The excretory cycle in this larva follows: The body fluid is filtered through the free portion of the Malpighian tubules, large mols. such as the proteins being rejected; the filtrate passes into the hind intestine and to its rectal region where most of the water and some dissolved substances are returned to the body fluid. No evidence was found that the chlorides of Na, K and Ca, nor the N compds., glycine, glutamic acid, uric acid and urea, are selectively filtered by the Malpighian tubules. Proof of the ion cycle was obtained through the use of radioactive NaCl. Rate of filtration by the tubules in isotonic saline soln. is 2.2 cu. mm. per hr.; it is lower in hypo- or hypertonic saline solns. The body fluid is isotonic with 2.12% NaCl soln. C. H Richardson

Increasing the life span of unfertilized Urechis eggs by acid. Albert Tyler and Frank W. Dessel. *J. Expl. Zool.* **81**, 459-72(1939).—The longevity of unfertilized eggs of the gephyrean worm, *Urechis caupo*, is increased by the addn. of acid to the nonsterile sea water medium. Optimum results are obtained at pH 5.5 either in buffered or unbuffered solns Prolongation of life is attributed to the extended immune period during which the egg is resistant to bacterial action. The acid probably toughens the egg surface. C. H. Richardson

The relation between salts, hydrogen-ion concentration and sensitivity to light in Peranema trichophorum. Landrum B. Shettles. *J. Expl. Zool.* **81**, 473-7(1939).—In solns. of NaCl, KCl, $MgCl_2$ and $CaCl_2$, resp., the photic reaction time of *Peranema* varies inversely with the concn. of the medium. The order of sensitivity to light is: Ca > Mg > K > Na. In solns. of single salts, sensitivity depends on the concn. and kind of salt. Sensitivity of *Peranema* to light is correlated with gelation (*C. A.* **28**, 5540[4]). C. H. Richardson

The ability of various liquids to penetrate the trachese [of insects] and its consequence. Hellmuth Gäbler. *Z. angew. Entomol.* **26**, 1-62(1939).—Penetration depends on low viscosity as well as low surface tension. The morphology of the stigmata is discussed. C. H. Richardson

The action of sex-attracting substances on the vine moths, Clysia ambiguella and Polychrosis botrana. Bruno Götz. *Z. angew. Entomol.* **26**, 143-64(1939).—The unfertilized females give off odorous substances which attract the males. The attraction increases with increased concn. of the substances; it is specific for each insect species. The chem. nature of the substances was not detd. C. H. Richardson

The control of white-reflecting chromatophores in Crustacea. F. G. W. Knowles. *Pub. staz. zool. Napoli* **17**, 174-82(1939) (in English).—Expts. indicated that the white reflecting chromatophores of *Leander serratus*, *L. adspersus* and *L. squilla* react directly (expand) in light but that in *L. adspersus* they are also secondarily affected by a hormone from the eye-stalks and nervous system.

The hormone contracting the white chromatophores may be a stage in the formation of the hormone contracting the red chromatophores. 13 references. W. C. Tobie

life-history and control of the Mediterranean flour moth (Kunike) 12. Factors affecting the resistance of the flour beetle to HCN (Gouch) 12.

The proximate chemical analysis of some Philippine foodstuffs. M. Gutiérrez. *Acta Med. Philippina* 1, No. 1, 47–52(1939); *Rev. filipina med. farm.* 30, 346.—Tabulated analyses of native foods are given. L. E. Gilson

Food inspection and analysis in Holland. J. Straub. *Analyst* 64, 717–25(1939).—Recent research work in Holland is reviewed and a bibliography given of 22 papers published during the last 6 yrs. W. T. H.

Decontamination of foodstuffs affected by poisonous gases. A. B. P. Page. *Chemistry & Industry* 1939, 906–9. G. G.

Regulations on standards of identity, quality and fill of container. *Federal Register* 4, 3320 (July 18, 1939).—General regulations are prescribed to emphasize the applicability of adulteration and misbranding sections of the Federal Food, Drug, and Cosmetic Act to food subject to regulations under the section authorizing the promulgation of standards. The general methods for detg. water capacity and fill of containers are detailed. The size and style of type and form of general statements of substandard quality, "Below Standard in Quality. Good Food — Not High Grade" and substandard fill of container, "Below Standard in Fill," are prescribed. H. A. Lepper

Agricultural and cannery waste utilization. Ernest H. Wiegand. *Western Canner & Packer* 29, No. 9, 13–16 (1937).—General. C. R. Fellers

Nutritive value of canned foods. E. F. Kohman, W. H. Eddy, Mary E. White and N. H. Sanborn. *Western Canner & Packer* 29, No. 9, 18(1937); cf. *C.* c1. 31, 7480[3]. C. R. Fellers

Capillary analysis of certified food dyes. Abraham Taub and Mario J. Ortega y Canet. *J. Am. Pharm. Assoc.* 28, 578–84(1939).—The method of capillary analyses has been adapted to the identification of the 13 H_2O-sol. certified food dyes when present individually. A special cabinet is described in which 13 tests can be carried out simultaneously under controlled temp. and humidity conditions. Com. compressed air (which has an extremely low moisture content) is passed through the cabinet at the rate of about 1 l. per min. to give a relative humidity inside the cabinet of 60 ± 5%. Strips (1 × 22 cm.) of S. & S. filter paper No. 604 (preferable to No. 597 or 598 owing to its softer texture) are immersed to a depth of 1 cm in beakers contg. a soln. of the dyes (optimum concn. about 0.1 *M*) with an appropriate electrolyte (for red dyes, approx. 0.25 *M* or 5% $Al(OAc)_3$, but better differentiation of Ponceau 3R and SX is obtained with 0.1 *M* NaCl; for yellow and orange dyes, 0.1 *M* Na_2SO_4, but better differentiation of Naphthol yellow S and tartrazine is obtained with 0.1 *M* HCl; for blue and green dyes, 0.1 *M* Na_2SO_4). After the strips stand for 30 min., they are raised above the soln. and allowed to dry. The nature of the dyes can be detd. from the height of the capillary rise, which should preferably be compared with that of pure dyes detd. simultaneously and under the same conditions of concn. For identification of more than one dye in the presence of each other, a method of successive capillarizations has been developed. After completion of the first capillarization and drying, the colored strip is again capillarized, under similar conditions of humidity, temp. and time, by immersion to a depth of 1 cm in a 0.1 *M* soln. of $CaCl_2$ in 50% Me_2CO; this results in washing up the dye on the lower part of the strip by the capillary action of the colorless reagent, and when several dyes are present discrete bands of color are formed at different levels. Their identities can be confirmed by spectrophotometric exam. A. Papineau-Couture

Regulations on coal-tar colors. *Federal Register* 4, 1935–47(May 9) 3936–40(Sept. 16, 1939).—The Federal Food, Drug, and Cosmetic Act provides the listing of coal-tar colors which are harmless and suitable for use in foods, drugs and cosmetics and authorizes the certification of batches. These regulations define general terms, and provide specifications of impurities, notably As, Pb and heavy metals. Eighteen colors suitable for foods, drugs and cosmetics, 66 for drugs and cosmetics, and 29 for externally applied drugs and cosmetics are listed including lakes. A new system of naming the colors provides the use for which permitted, the predominant shade, and a no. distinguishing the color from others of the same shade for the same use. Each color is identified by the tech. name from the nomenclature adopted by the Am. Chem. Soc. Individual specifications of purity are given. Detailed certification requirements are provided. Corrections are published in *Federal Register* 4, 2255(June 3, 1939) and 4300(Oct. 20, 1939). H. A. Lepper

Iron contents of grains and vegetables of an endemic district of Kaschin-Beck disease. Eikiti Tanabe, Humito Eto and Tuyosi Hukuki. *J. Orientl Med.* 31, 175–8 (English abstr., 18)(1939).—Fe content of the grains produced in the endemic area of this disease is slightly greater than that of other districts, except that of millet which is several times greater. That of vegetables is 10–20 times greater. S. Yashiro

Studies on rice bran. K. Okada. *Münch. med. Wochschr.* 86, 290–2(1939).—Production and uses of rice bran are discussed. Maurice M. Rath

Determination of soybean flour in sausage by nonfermentable sugars. W. B. Hendrey. *Ind. Eng. Chem., Anal. Ed.* 11, 611–13(1939).—The sausage is ground and evapd. with alc. The oil is extd. with petr. ether. Water-sol. sugars are removed with 50% alc. and may be detd. if desired. The residue is hydrolyzed with HCl, by boiling 3 hrs. Insol. sugars can be detd. at this point. A sample of the soln. is fermented with yeast, and the nonfermentable sugars in the filtrate are detd. by A. O. A. C. methods. Amy LeVesconte

Flour granularity. D. W. Kent-Jones, E. G. Richardson and R. C. Spalding. *J. Soc. Chem. Ind.* 58, 261–7 (1939).—Granulation is important because of influence on baking qualities. Some of the principal difficulties encountered in attempting to make and record such measurements are discussed and a method is suggested by which the percentage masses of the particles between various sizes, measured in steps of 10 μ, can be recorded. The method is an adaptation of the sedimentation methods which have been recommended and used satisfactorily in measuring the particle sizes of soils and it rests on the application of Stokes' law. The decrease in the cloudiness of a dil. gasoline suspension of flour is measured at a fixed depth by the increase in the intensity of a beam of light which is measured by means of a photoelec. cell. By the assumption that Stokes' law holds under the conditions of the expt. an actual record of the distribution of particle size between normal limits can be obtained. For practical use by millers the results are also given as the percentage mass of particles larger than 45 μ and smaller than 45 μ. In the av. flour used by bakers about 50% of the particles are larger than 45 μ and 50% smaller. Strong flour made from hard wheat tends to be coarser and to have about 55% of the particles larger than 45 μ. Soft flours, especially those classed as cake flours, often show less than 10% of particles larger than 45 μ, the majority being between 15 and 25 μ. The method can be applied to the various flour streams made in the mill in the process of manufg. commercially sold flours and may indicate to the miller an abnormality that he might otherwise have missed. Otto Johnson

Life-history and control of the Mediterranean flour moth, Ephestia kuehniella Z. (Pyralidae, Phycitinae). Georg Kunike. *Z. angew. Entomol.* **25**, 588–608(1938–9).—Practical control measures are described. C. H. R. 1

Factors affecting the resistance of the flour beetle, Tribrolium confusum Duv., to hydrogen cyanide. H. C. Gouch. *Ann. Applied Biol.* **26**, 533–71(1939).—The order of resistance of the stages of *Tribolium* to HCN is: pupa > adult > larva > egg. Cotton's theory (*C. A.* **27**, 800) might hold for stages other than the egg. Expts. to demonstrate inheritance of individual resistance to HCN showed that offspring of resistant individuals were significantly more resistant than those of susceptible individuals. This difference was maintained over several generations. Resistance was increased if adults were removed from their flour medium about 1 hr. before instead of at once before fumigation. Under certain conditions, the beetles emit a volatile substance which is self-toxic and appears to react with HCN. Methods and variations in the toxicity data are discussed. C. H. Richardson 2 3

Combination baking powders. Simon Mendelsohn. *Food Manuf.* **14**, 313–16(1939).—Formulation and compn. are given. Otto Johnson

The colorimetric estimation of biacetyl and acetoin in dairy products. G. A. Cox and W. J. Wiley. *J. Council Sci. Ind. Research* **12**, 227–31(1939).—The colorimetric method for the estn. of biacetyl as proposed by Pien, Baisse and Martin (cf. *C. A.* **31**, 6751[2]) was investigated and certain modifications and extensions were introduced which are given in detail. The method was found to be reasonably accurate and, on account of its speed and ease of manipulation, preferable to the Ni dimethylglyoxime method. J. C. Jurriens 4

Methylene blue reduction test. I. Raw milk test after Wilson's modification. T. Matuszewski and J. Supińska. *Zentr. Bakt., Parasitenk.*, II Abt. **101**, 45–64 (1939)(in English).—See *C. A.* **33**, 2599[2]. J. T. M. 5

Methylene blue reduction of duplicate samples of raw morning milk held overnight at 40° F. and 60° F. Hannah M. Powell, Elin Jenkins and S. B. Thomas. *Welsh J. Agr.* **15**, 164–8(1939).—Both winter and summer samples of morning milk gave an av. methylene blue reduction time which was 3.5 hrs. longer for portions held overnight at 40° F. than for duplicates held at 60° F. The mean difference in reduction time increased from 54 min. in the case of samples reducing within 2 hrs. after holding at 40° F., to 4.33 hrs. in the case of samples being reduced within 6.5–8.0 hrs. Holding at 40° F. during winter had a retarding effect on methylene blue reduction, whereas holding at 60° F. appeared to be too drastic a treatment in summer; holding at 50–55° F. is recommended for all seasons. K. D. Jacob 6

A comparison of different methods of performing the methylene blue test. A. Mildred Williams, May Davies and S. B. Thomas. *Welsh J. Agr.* **15**, 169–72(1939).—The old methylene blue test was compared with the Wilson modification (cf. *C. A.* **31**, 3162[6]) on 301 samples of raw milk. The modified technique gave little av. difference in reduction time from the old method for samples reducing within 5.5 hrs. A very slight av. increase in reduction time was obtained with the modified test in the case of the poorer-quality samples that reduced within 3 hrs., but there was a marked decrease in reduction time with the better-quality samples. K. D. Jacob 7

The variability of the methylene blue test. G. M. Phillips, W. M. Ashton, G. D. Simons and S. B. Thomas. *Welsh J. Agr.* **15**, 172–80(1939).—In a series of high-grade milk samples examd. by 4 sep. workers during winter, the av. of the max. variations in methylene blue reduction time was 1 hr. and 23 min. and the av. coeff. of variation was 6.5%. In a series of low-grade samples examd. by the same 4 workers during summer, the av. of the max. variations was 46 min. The variations observed during the course of the tests showed a gradual increase according to increasing reduction times. A series of accredited milk samples tested in duplicate by 1 worker showed no variation in samples reducing within 5 hrs.; small variations were observed in the better-quality milk, but the highest av. variation for any group of samples was only 15 min. The magnitude of the variation in reduction time seems to be influenced by the intervals between examn. of the tubes, quality of milk tested, no. of workers and the personal factor. Half-hourly inversion of the tubes improved the reproducibility of the reduction times. K. D. Jacob 8

The resazurin test—a comparison with the modified methylene blue test. Jane Davies, Blodwen F. Thomas and S. B. Thomas. *Welsh J. Agr.* **15**, 181–9(1939).—The resazurin and methylene blue tests were compared on 575 samples of accredited raw milk, with examn. and inversion of the tubes at 30-min. intervals in both tests. The reduction of resazurin to the white stage correlated very well with, but was distinctly slower than, the methylene blue reduction; the av. difference was 35 min. The reduction of resazurin to purple pink also gave a fair statistical correlation with methylene blue reduction, but about 10% of the samples that reduced resazurin to this stage in 1 hr. failed to reduce methylene blue in 7 hrs. The resazurin test can be utilized for advisory purposes, particularly when used in conjunction with microscopic examn., and samples that retain the original blue color for 1 hr. at 37° can be considered satisfactory. K. D. Jacob 9

The value of the Hotis test in detecting mastitis streptococci in milk. James M. Murphy. *Cornell Vet.* **29**, 279–86(1939).—The bromocresol purple test, described by Hotis and Miller (*U. S. Dept. Agr. Circ.* No. **400**(1936)), could not be relied upon to indicate the presence of mastitis streptococci in 95% of cases unless the streptococci were of Minett's group I. If infection with streptococci of other groups greatly predominated in the herd, the efficiency of the test might be reduced to as low as 10%. K. D. Jacob 10

The riboflavin content of cow milk. David B. Hand and Paul F. Sharp. *J. Dairy Sci.* **22**, 779–83(1939); cf. *C. A.* **33**, 5924[7].—The riboflavin content of about 400 samples of milk was detd. by the measurement of the intensity of fluorescence of an acetone filtrate by a photoelec. cell. The riboflavin ranged from 0.60 to 3.42 mg. per l. A neg. skew correlation of 0.830 was found between riboflavin content and milk production. Com. milk in summer contained about 20% more riboflavin than winter milk. Cows, after being fed in winter on phosphoric acid, grass silage, showed no increase in riboflavin when turned out on green pasture. The av. riboflavin content of milk varied with the different breeds, Jersey being highest, Guernsey intermediate and Holstein lowest. A few tests with Ayrshire and Brown Swiss gave riboflavin values intermediate between Holstein and Guernsey cows. A. H. Johnson 11

Effect of ultraviolet ray on vitamin C content of milk. H. Schroeder. *Munch. med. Wochschr.* **86**, 801–2(1939).—Irradiation with a Hg-quartz lamp diminished the vitamin C content of milk to 50% in 10 min. and destroyed all in 1 hr. Maurice M. Rath 12

The influence of the physical character of the roughage on the percentage of fat secreted in the milk. Dwight Espe and C. Y. Cannon. *J. Dairy Sci.* **22**, 799–801 (1939).—The percentage of fat in the milk was not materially influenced by grinding the dry roughage in the ration to a meal. The roughages tested were corn fodder and alfalfa hay. A. H. Johnson 13

The freezing point of milk. Lincoln M. Lampert. *J. Assoc. Official Agr. Chem.* **22**, 768–71(1939).—An examn. of published data and of new data indicates that 0.540° is a more desirable figure than 0.550° for the av. f.-p. depression of pure milk. A. Papineau-Couture 14

Sodium alginate as a stabilizer. Merrill J. Mack. *Food Ind.* **10**, 195–6, 225(1938); cf. *C. A.* **31**, 4733[8].—Na alginate is more effective lb. for lb. than av. high-gelatin when used as a stabilizer in ice cream. Normally, less than 0.5% is used. The use of 0.1–0.2% of Na alginate in cream is effective in decreasing serum drainage. In cheese the amts. suggested are 0.1–0.2%. The mix should be heated to at least 71° before adding the stabilizer to obtain prompt and complete soln. C. R. Fellers 15

Determining riboflavin in dried milk products. Royal

A. Sullivan and L. C. Norris. *Ind. Eng. Chem., Anal. Ed.* **11**, 535–40(1939).—The concn. of riboflavin in an ext. of dried milk powder or whey, first oxidized to destroy unstable colored impurities, is calcd. from the difference of light absorption before and after reduction of the riboflavin to the leuco form. A specially constructed *photoelec. photometer*, utilizing a zero potential circuit in connection with a blocking layer photocell, and having an instrument correction of 15%, is described. To prep. the ext. a 15% soln. of the material in a 75% soln. of acetone in H_2O is acidified to 0.1 *N* with H_2SO_4, treated with 1–3 ml. of 30% H_2O_2 per l. of soln. and refluxed for 20 min. The soln. is cooled and neutralized and 22–24% of buffer soln. added. Buffer of 6.8 is used for dried whey and of 4.6 for dried skim milk and dried buttermilk. Photometer readings are made on the filtered soln. The reducing agent is $Na_2S_2O_4$, which reduces 90% of the riboflavin under the conditions used. The absorption curve for pure synthetic riboflavin is given over the range 4900–5000 A. Its mol. extinction coeff. was found to be 2.78 × 10^4 at 4450 A. The photometric detns. checked well with chick assays. H. K. Salzberg

Factors influencing the quality and chemical composition of butter. R. O. Davies and E. K. Griffiths. *Welsh J. Agr.* **15**, 189–201(1939).—Samples of farmhouse and factory butters marketed in Wales were examd. for quality and chem. compn.; greater uniformity was found in the factory samples. There was no relation between the true moisture in butter and the moisture which exudes on the application of pressure and on which the score for freedom from moisture depends. While factory samples contained less apparent moisture, the actual moisture content exceeded that of farm butter by a wide margin. The chloride and protein contents of the samples fluctuated considerably. Butter that had a high protein content was not necessarily inferior in keeping quality provided it showed freedom from excess of intragranular protein. The keeping quality was closely related to the initial acidity of the butter and decreased with increase in the acid content. During storage of the samples, the contents of both sol. and total acids steadily increased to max. values and then decreased. The Reichert-Meissl no. of Welsh butter showed a definite seasonal change, the max. corresponding to the period of the yr. when most of the freshly calved cows entered the milking herds. The av. carotene content of New Zealand butter was higher than that of Welsh butter. Summer grazing had a marked effect in raising the concn. of unsatd. fat acids and of carotene in Welsh and Danish butter. K. D. Jacob

The formation of biacetyl by starter cultures. I. A comparison of single strain and mixed culture starters for butter manufacture. W. J. Wiley, G. A. Cox and H. R. Whitehead. *J. Council Sci. Ind. Research* **12**, 232–8 (1939).—In a series of buttermaking expts. with cream held with a starter overnight at 7°, it was found that starters without aroma imparted as much "brightness" to the butter as did those possessing a high aroma. This "brightness" correlated well with the biacetyl (*A*) content of the butter and the cream from which it was made. The *A* content of the cream did not correlate with the *A* content of the starter with which it had been inoculated. Lab. expts. showed that: (*a*) *A* production is greater in cream or milk flash-pasteurized and aerated during the cooling process than in steam-sterilized milk; (*b*) that *Str. cremoris* produces about the same proportion of *A* at 7° as at 21°, although its acid production is negligible at the lower temp.; (*c*) that betacocci of a mixed starter have very little influence on the proportion of *A* produced at 7°, although they are known to be mainly responsible for the *A* production at 20°. **II. Rate of biacetyl production by lactic streptococci.** *Ibid.* 239–49.—Single strains of *Str. cremoris* grown in milk at 21° produced proportions of *A* amounting to 1 p. p. m. within 24 hrs. and remained const. for 21 days. When grown at 7° their initial rate of production of *A* was less, but remained const. for a longer period, so that after about 100 hrs. about twice as much was produced as at 21°. Butter cultures contg. betacocci grown in milk at 7° produced *A* in a similar manner to *Str. cremoris*. At 21°, however, there was a rapid production of *A* during the period of logarithmic growth rate of the organisms. The proportion produced was 10 p. p. m. After reaching a peak value it fell rapidly, about 90% of the *A* being destroyed in about 12 hrs. Cultures of betacocci, when grown in milk at 21°, produced no appreciable quantities of *A* over a period of 100 hrs. However, when grown in milk acidified to pH 4.2, they produced and destroyed *A* in a similar manner to butter cultures. Acetoin was destroyed in a similar manner. There is no explanation as yet for the striking phenomenon of rapid production followed by rapid destruction of *A* during such a short period of time. J. C. Jurrjens

Production of margarine. A. V. Hammer. *Kälte-Ind.* **36**, 25–30(1939).—Comprehensive description, 4 photographs, 2 diagrams. S. Landeker

Sodium bisulfite as a stabilizer for hydrogenated cottonseed-oil shortening. K. S. Hoover and H. E. Moore. *Oil & Soap* **16**, 212–14(1939).—Hydrogenated, deodorized cottonseed-oil shortening, when treated with about 0.022% of a satd. soln. of $NaHSO_3$ at 120°F., may be given increased keeping time and lowered peroxide values. The flavor of the treated shortening will be good; but it will contain a trace of SO_2. The keeping time of 1500 g. of shortening when treated with 0.25 cc. of satd. $NaHSO_3$ soln. was increased 48 hrs. and the initial peroxide value lowered about 77%. E. Scherubel

Definitions and standards for egg products. *Federal Register* **4**, 3375–8(July 20, 1939).—Regulations under the Federal Food, Drug, and Cosmetic Act give the identity definitions and standards for liquid (mixed, liquid whole, mixed whole) eggs as the yolks and whites in their natural proportions as broken from the shells; frozen (frozen whole, frozen mixed) eggs as liquid eggs frozen, and dried (dried whole) eggs as liquid eggs dried to a min. solid content of 92%. Egg yolks (liquid egg yolks, yolks, liquid yolks) are yolks of eggs so sepd. from the whites as to contain not less than 43% total egg solids; frozen (frozen egg) yolks are egg yolks frozen and dried egg (dried) yolks are egg yolks dried to a min. of 95% total solids. These egg products are restricted to the eggs of the domestic hen. H. A. L.

What technology is doing for the fishing industry. John R. Manning. *Food Ind.* **10**, 191–2, 222–3(1938).—The applications of chemistry to the technology of fishery products are discussed in the light of the research program carried on by the U. S. Bureau of Fisheries in its several labs. C. R. Fellers

Manufacture and use of ice containing CO_2 for lengthening the storage time of fish. H. Keller. *Z. Fleisch- u. Milchhyg.* **49**, 469–71(1939).—Ice contg. CO_2 (I) was prepd. according to 2 methods: use of ice cell covered with acidone and by bubbling the gas through the cell contents. The absorption of CO_2 was quick when applied under pressure with agitation. Simply bubbling CO_2 in the water-filled ice cell will not yield I. The I melts more quickly than ordinary ice. In comparison tests the I was not superior to ordinary ice for fish preservation and was therefore not recommended. M. M. Piskur

Quick-frozen fish filets. The role of preservatives in enhancing keeping quality. H. L. A. Tarr and P. A. Sunderland. *Ice and Cold Storage* **42**, No. 495, 91–2 (1939).—The comparative preservative actions of Na benzoate, benzoic acid, KNO_2, H_2O_2, $CHCl_3$, boric acid, HCl, SO_2 and *p*-hydroxybenzoic acid Et ester for fresh flounder and frozen halibut are given. A. H. Johnson

Quick freezing and small containers. The commercial problems of packaging materials. E. P. Melhart. *Ice and Cold Storage* **42**, No. 496, 107(1939).—Com. phys. and chem. problems involved in packages to be used for quick-frozen foods are discussed. The chem. aspect embraces the minimizing of chem. and enzymic changes in the product by preventing the entrance of outside air. For strawberries the container must be waterproof; for peaches a container able to withstand a vacuum is desirable. A container capable of controlling desiccation of the product is also necessary. A. H. Johnson

Regulations for inspection of canned shrimp. *Federal Register* **4**, 2397–2401(June 14, 1939).—The revised

regulations applying to inspection of canned shrimp, provided in the amendment to the Federal Food and Drugs Act of 1906, which remains in force under the Federal Food, Drug, and Cosmetic Act of 1938, are promulgated as effective July 1, 1939. H. A. Lepper

Latest investigations in pectin materials. Antonios N. Nikolaos. *Chim. Chronika* (Greece) **4**, 175–7(1939)(in Greek). Lucien Y. Dyrenforth

Effect of oxygen and carbon dioxide on the chemical change in stored apples. Franklin Kidd and Cyril West. *New Phytologist* **38**, 105–22(1939).—The starch and sugar fraction, the alc.-insol. fraction (excluding starch) and the acid fraction contribute to the loss of CO_2 in respiration. The rate of sucrose hydrolysis is not affected by O tension of the atm. but is increased by CO_2. The rate of hydrolysis of the alc.-insol. fraction is decreased by CO_2. The results indicate the existence of a fructosan in the alc-sol. fraction. Fructose units are produced during the hydrolysis of starch. H. R. Kraybill

From apple cider to apple juice. Karl L. Ford. *Canning Age* **19**, 302–4, 320(1938). By washing apples to be used for apple juice with a 1% soln. of HCl, most of the Pb and As residues on the skins is removed. Clarification is best effected by means of Pectinol (a com. pectin-dissolving enzyme). The enzyme should act for 12–18 hours at normal temps. or for 3 hrs. at 120°F. One lb. of enzyme prepn is sufficient for 100 gals. of juice. Apple juice may be satisfactorily canned in special enamel-lined Sn cans. C. R. Fellers

Ethylene of limited value in ripening of Yakima pears. Observations of the effect of ethylene on the softening of Bartlett pears. Wm. Rabak. *Western Canner & Packer* **31**, No. 4, 26–8(1939).—The use of C_2H_4 is of only limited value in artificially ripening Bartlett pears for canning. Pears soften satisfactorily under controlled temp. conditions without using C_2H_4. C. R. Fellers

An objective method for measuring grittiness in canned pears. L. M. Beacham. *J. Assoc. Official Agr. Chem.* **22**, 706–8(1939).—The method consists essentially in allowing the pears to drain, grinding to a homogeneous mass in a food chopper, placing 50 g. in the cup of a malted milk stirrer, adding 200 cc. of water and 25 cc. of 50% NaOH, boiling vigorously for 5 min., stirring 5 min., filtering through a tared 30-mesh monel wire screen, washing copiously with hot water, drying at 100° for 1 hr. and weighing the grit cells. A table is given showing the percentage by wt. of such grit cells in samples of canned Bartlett, Kiefer and Pineapple pears and comparing them with organoleptic examn. of such pears. Pears contg. only cells smaller than 0.02 in. may be chewed and swallowed without any impression of the presence of hard material. Bartlett pears were smooth to the taste and showed a residue of 0.01–0.06% residue; Kiefer pears were gritty to the taste and showed a residue of 0.36–0.54%; Pineapple pears were gritty to the taste and showed a residue of 0.19–0.31%. A. P.-C.

Manufacture of Maraschino cherries. Ernest H. Wiegand. *Western Canner & Packer* **28**, 5–6(1936); **29**, 33–4(1937); cf. *C. A.* **25**, 1919.—For bleaching the cherries a brine contg. 1–1.5% SO_2 and 5 7 lb. of $Ca(OH)_2$ or $CaCO_3$ per 100 gal. is recommended. Strength of the SO_2 soln. is maintained and checked during the storage process by occasional titration with standard 0.1 *N* I_2 soln. The bleaching requires about 30 days. The brining causes a loss in wt. of the fruit of about 7–12% and pitting an addnl. 15–20%. Fresh water leaches out the SO_2 and lime in about 24–48 hrs. To reduce the SO_2 to below 50 p. p. m. the fruit must be boiled for 10 min. For coloring about 0.5–0.7 oz. of Ponceau 2R dye per 100 lb. of fruit is used. The first sirup contains approx. 30% sucrose and 0.4% citric acid. The d. of the sirup is increased by about 5% sugar each day until it reaches 40–45%. C. R. Fellers

A rapid method for (determining) chlorides in tomato products. L. M. Beacham. *J. Assoc. Official Agr. Chem.* **22**, 765–6(1939).—The method consists essentially in adding 5 g. of tomato material to about 50 cc. with 80% alc., adding 1 cc. concd. HNO_3 and 25 cc. of 0.1 *N* $AgNO_3$, making to exactly 100 cc. with 80% alc., centrifuging at 1800 r. p. m. for 5 min., and titrating the excess of Ag in a 50-cc. aliquot by means of 0.1 *N* NH_4CNS. The results obtained by this method are as accurate as those by the present official A. O. A. C. method. A. P.-C.

Copper content of tomatoes and tomato products. F. C. Lamb and P. R. Lloyd. *Western Canner & Packer, 29th Yearbook* **31**, No. 5, 77–8(1939).—Even with a slight or moderate Cu contact of tomato products with Cu-contg. materials, the amt. of Cu present may be 50 p. p. m. The present United Kingdom tolerance is 100 p. p. m. It is recommended that all Cu equipment be thoroughly cleaned before running tomato products through it. Max. metallic contamination occurs at the start of the day's run. C. R. Fellers

The relation of acidity to the vitamin C content of the tomato. Mary Yarbrough and G. Howard Satterfield. *J. Elisha Mitchell Sci. Soc.* **54**, 186–7(1938).—See *C. A.* **33**, 8844⁶. Colin W. Whittaker

Standards for tomato puree and paste. *Federal Register* **4**, 3225–7(July 18, 1939).—Regulations under the Federal Food, Drug and Cosmetic Act provide definitions and standards of identity for tomato puree (tomato pulp) and tomato paste as of red or reddish varieties. Provision is made for optional use of tomato material other than whole tomatoes with appropriate label declaration. With paste, salt, spice, flavoring and $NaHCO_3$ are provided as optional ingredients, with a requirement for label declaration of all except salt. The salt-free tomato solids in puree must be not less than 8.37% but less than 25% and in paste not less than 25%. H. A. Lepper

Conservation of vitamin C in tomato-juice production. N. H. Sanborn. *Glass Packer* **17**, 102–3(1938).—The vitamin C content of raw tomatoes may vary as much as 100% depending on variety and growing conditions. It is essential to exclude air during the manufg. process to retain the max. amt. of ascorbic acid. Each operation should be designed to prevent oxidative changes. Steam pumps beat less air in the juice than centrifugal pumps. Losses occur in holding tanks. In 1 case the loss in a holding tank was 19% in 13 min. The use of viscolizers or colloid mills prevents the sepn. of insol. material in the canned or bottled juice. The most complete conservation of ascorbic acid was found in juice prepd. by the "hot-break" process. C. R. Fellers

Faulty plant equipment, a cause of spoilage in tomato juice. W. E. Pearce and E. H. Ruyle. *Glass Packer* **17**, 243–5, 253(1938).—*B. thermoacidurans*, the organism which causes much of the "flat-sour" spoilage in canned tomato juice, may survive temps. of 212°F. for 30 min. and may therefore survive com. thermal treatments. C. R. Fellers

Standards of fill of container, identity and quality and label statements for canned tomatoes *Federal Register* **4**, 3321–5(July 18, 1939).—Regulations under the Federal Food, Drug, and Cosmetic Act provide a standard of fill of container and a definition and standard for canned tomatoes as of red or reddish varieties. Provision is made for addn. of optional liquid ingredients derived from tomatoes with labeling requirements. Of the optional ingredients, salt, spices and flavoring, the latter 2 must be declared on the label. The standard of quality includes the factors of drained weight, color, amt. of peel and blemishes. Statements for labeling tomatoes substandard in quality or fill of container are provided. H. A. L.

Products from the papaya. Susan Howe Clark. *Glass Packer* **16**, 774–5(1937).—The manuf. of various edible papaya products such as pulp, juice and sirup is briefly described. Papain is obtained only from the unripe fruit or other parts of the plant. C. R. Fellers

Maturity test for peas. S. L. Jodidi. *Canning Age* **19**, 297–300, 336–8(1938); cf. *C. A.* **31**, 5051⁸.—The sp. gr. of peas varies directly with their starch:sugar ratio and since this ratio is known to be a good index of maturity, it follows that the sp. gr. is a good index of quality or maturity in peas in the case of Surprize, Perfection and Alaska varieties. Peas mature very rapidly once they are nearly mature and at proper canning texture. In general,

the sucrose percentage varied directly with the water content, while the starch percentage varied directly with the dry matter content. The percentage of reducing sugar in Perfection peas is usually less than 1%, and often less than 0.5%; wrinkled pea varieties are somewhat higher in reducing sugar content. In chem. compn. the Alaska variety was most variable. Methods of ascertaining pea tenderness and quality are reviewed. App. for making the recommended sp. gr. test on peas is described.
C. R. Fellers

Effect of the rate of freezing on the texture of peas. E. W. Eickelberg. *Canning Age* **19**, 108–9, 512(1938). Quick-frozen peas have fewer ruptured cells and are superior in color and flavor to slow-frozen peas at higher temps. There is a more marked reduction in the nos. of microörganisms in the quick-frozen product. Enzyme activity is likewise reduced materially at the lower temps.
C. R. Fellers

The effect of the culinary treatment of potatoes upon the accessibility of the starch to amylase. F. M. Porodko, E. L. Rosenfel'd and I. Ya. Solovechik. *Voprosy Pitaniya* **8**, No. 2, 109–22(1939). The boiling or baking of potatoes aids in the accessibility of the starch (I) to amylase by destruction of the cell tissue and gelatinization and increase in the thermal hydrolysis of I without materially dehydrating the gel, as occurs when the potatoes are fried.
S. A. Karjala

Use of salad oils in mayonnaise manufacture. R. G. Dressler. *Western Canner & Packer* **29**, No. 10, 32–3 (1937). Mayonnaise consists of 70–80% oil. Characteristics of oils suitable for mayonnaise are described. The free fat acid content of the oil should not exceed 0.05%, color 5 red 35 yellow, clear free from contamination and suspended matter, cold test 5½–15 hrs., bland flavor, good stability and of a type which emulsifies well in the usual mayonnaise formula. The practice of winterizing is to crystallize and filter out the glycerides which solidify on prolonged standing at 40°F., leaving the salad oil contg. only the lower-melting glycerides, which are more homogeneous and stable in mayonnaise emulsions. If a salad oil contains over 0.07% moisture a cloud will appear. The Kreis test is of little value in evaluating oils for use in mayonnaise manuf.
C. R. Fellers

Manganese and caffeine contents of some teas and coffees. D. R. K. Coleman and F. C. Gilbert. *Analyst* **64**, 726–30(1939). Fifteen samples of black teas and 6 samples of raw coffee beans were analyzed to see whether the Mn content had any relation to the caffeine present. The methods of analysis are described fully. In the teas, the Mn content ranged from 0.008 to 0.14% and the caffeine from 2.45 to 4.7%. In general, the higher the Mn content, the lower the caffeine value. With coffee, on the other hand, the caffeine content was fairly const. at 0.90 to 1.3% and the Mn at 0.0014–0.0032%.
W. T. H.

Spices play part in many preserved food products. C. A. Thayer. *Western Canner & Packer* **31**, No. 3, 27–8 (1939). General data on spices.
C. R. Fellers

Problems in the preservation of green fodder. Gutermann. *Chem.-Ztg.* **63**, 645–7(1939). A review. G. G.

The effect of partial field-drying and artificial drying on the chemical composition of grass. T. W. Fagan and R. Probert Davies. *Welsh J. Agr.* **15**, 261–71(1939); cf. *C. A.* **32**, 7598[2]. The wilting of mown grass in the field or under cover had little effect on the percentage of protein in the dry matter. The av. loss of carotene after wilting for 48 hrs. in the field was 26%, whereas the loss was 16 and 11%, resp., when wilting took place under cover or in jute scrim bags. The most serious loss of carotene occurred when the herbage was exposed to rain and sunshine. There was evidence that the loss of carotene was greater in those samples which were originally rich in this constituent. K appeared to be the mineral constituent most liable to loss when herbage wilts under unfavorable conditions.
K. D. Jacob

A modified procedure for the determination of carotene in silage. A. C. Neish, W. D. McFarlane, and W. A. Beechin. *Can. J. Research* **17**, B, 325–30(1939). The pigments in silage which were formed from xanthophyll by acids and which interfere in the detn. of carotene were sepd. by chromatographic methods and found to exhibit solubilities intermediate between those of carotene and xanthophyll. A method based on the partition coeff. of carotene and the interfering pigments in the system hexane–benzyl alc. gave reliable estimates of carotene.
J. W. Shipley

Shark-liver oil a potent source of vitamin A for poultry. L. L. Rusoff and N. R. Mehrhof. *Poultry Sci.* **18**, 339–44 (1939).—Admstd. by expts. on chicks, a sample of shark-liver oil (poultry grade) from Florida contained approx. 9000 U. S. P. XI units of vitamin A per g. K. D. J.

Seasonal fluctuation in the Mn content of four grass species (Wain, *et al.*) **11D**. Chem. compn. of the seed and straw of various grasses (Davies) **11D**. Modern chemistry, modern medicine and modern food (Dodds) **2**. Starch of immature linseed (Dodd) **26**. Relation of the I contents of milk and pasture to the occurrence of endemic goiter (Orr, *et al.*) (Crabtree, Mason) **11G**. App. for heating, cooling, kneading, grinding and emulsifying in margarine manuf. (U. S. pat. 2,170,303) **1**. Subjecting liquids to sound vibrations for homogenizing milk (U. S. pat. 2,170,178) **1**. Laminated paper for wrapping butter, etc. (U. S. pat. 2,171,775) **23**.

Hempel, Bruno, and Kirchhof, Hans: Obst-Halbfabrikate. Einfache Haltbarmachung von Obst zu Pulpe, Mark, Saft durch Rohkonservierung und Trocknen. 2nd. ed. Braunschweig: Berger & Hempel. 78 pp. M. 3.

Cereal preparations. Albert E. Berry. Brit. 507,384, June 14, 1939. In making flaked products from cereal grains, e. g., corn, oats, rice, by conditioning and softening by addn. of H_2O, cracking by passage through rollers to release the germ and form grits, sepg. the grits from the meal and germs and cooking them, e. g., with steam, and flaking by passage between rollers, which may be heated, steep H_2O rich in org. phosphates and protein, produced by steeping corn in H_2O contg. a small percentage of SO_2 in the manuf. of starch from the corn is added at a stage in the process before the finished cereal product is obtained.

Deodorizing gases evolved in roasting grain, etc. Michael M. Jalma and Henri Coutinho. Brit. 505,971, May 18, 1939. Gases given off from the roasting of vegetable materials, e. g., coffee, cacao beans, peanuts, cereals, which gases contain org. compds. of high mol. wt. and no substantial quantity of O_2 are purified by being heated to a high temp. to crack the org. compds. to compds. of lower mol. wt., O_2 being added to the cracked gases and the org. compds. therein being then oxidized. App. is described.

Vitamin preparations. André E. Briod and Bion R. East. Brit. 506,730, June 5, 1939. A prepn. adapted for adding to foods is obtained by emulsifying vitamin D concentrate without extraneous emulsifiers, with unsweetened cream or evapd. milk and thereafter sterilizing the emulsion. The evapd. milk may be replaced by a product of approx. the same compn. made from milk powder. The emulsion may be incorporated in whole milk or in bread or other cereal products, or may be dried, e. g., by spray or roller drying, and added, e. g., to powd. milk.

Short pie-crust doughs, etc. Robert L. Lloyd (to American Maize-Products Co.). U. S. 2,172,211, Sept. 5. In a short-unleavened, baker compn. contg. flour and a relatively large amount of shortening, there is used a substantially dry, comminuted, solidified starch-conversion sirup having a reducing-sugars content calcd. as dextrose of about 30–60% and the remainder principally dextrins, the solidified sirup having the property of caramelizing at a lower temp. than any of the other ingredients in the compn. and imparting to the bakery product made therefrom substantially greater uniformity in browning and substantially greater resistance to moisture absorption from bakery fillings than such product made without the solidified sirup or made with sucrose or dextrose.

Baking powders. Willard L. Morgan (to America

Maize-Products Co.). U. S. 2,170,274, Aug. 22. Phytic acid or an acid salt such as a Ca phytate or acid Na, K or NH_4 phytate is used with other compds. such as $NaHCO_3$ and starch.

Preserving cream or whole milk. Musher Foundation, Inc. Brit. 506,161, May 16, 1939. The cream, etc., is stabilized against oxidative deterioration by being mixed with not exceeding 5% of a raw cereal flour, the amt. used being sufficient substantially to retard development of oxidized tastes and flavors. An ext. obtained by mixing the flour with H_2O or alc., sepg. the starch and cereal fibers and evapg. the H_2O or alc. may be used instead of the flour. Oat, yellow and white maize and barley flours may be used.

Preserving ice creams. Musher Foundation, Inc. Brit. 506,031, May 16, 1939. Divided on 506,161 (preceding abstr.). Fruit-flavored and other ice creams are mixed with an amt. of oat flour or hominy not exceeding 2% but sufficient substantially to retard development of oxidized tastes and flavors. Alternatively, an ext. obtained by mixing the flour or hominy with H_2O or alc., removing the undissolved starch and cereal fibers and, if desired, concg. may be used. The addn. may be made e. g., in admixt. with the sugar, to the ice-cream mix before pasteurization and homogenization or to the fruit, e. g., strawberries, while in gold storage prior to its utilization in the prepn. of the ice cream.

Drying whey. Charles O. Lavett (to Buffalo Foundry & Machine Co.). U. S. 2,172,393, Sept. 12. An arrangement of app. is described, and a method of drying whey which may involve preconcg. the whey under vacuum to a soln. contg. about 40–50% solids, thereafter subjecting the preconed. whey to an intermediate concn. under atm. conditions at about its b. p., to a concn. of about 85–92% solid content, followed by rapid cooling to about 93° and further cooling and crystg. of the preponderance of the lactose content in the form of the alpha hydrate.

Tubing suitable for sausage casings. Richard Weingand and Arnold Muehlinski (to Sylvania Industrial Corp.). U. S. 2,172,426, Sept. 12. A seamless flexible tubing is formed from a colloidal plastic material such as a viscose or nitrocellulose soln. by extrusion (in a described app.), partially hardened, as by a coagulating bath, then expanded 40–100% its original diam., and the hardening is completed after such expansion.

Stabilizing compositions for use with sausage emulsions. Carroll L. Griffith and Lloyd A. Hall (to Griffith Laboratories, Inc.). U. S. 2,171,428, Aug. 29. Blood-serum solids 3–40, milk 97–60 and a vegetable gum such as Irish moss gum 25 parts or less are used together.

Salad dressing. Harry M. Levin. U. S. 2,170,417, Aug. 22. A homogeneous viscous emulsified salad dressing base is formed of ingredients such as milk 100 gal., starch 68 lb., a hydrophillic colloid such as gelatin, locust-bean gum or gum tragacanth 0.75–1.0 lb., and a small proportion of acetic, lactic or citric acid (various details and modifications being described).

Foods such as salad dressings. Albert Musher (to Musher Corp.). U. S. 2,170,518, Aug. 22. A salad-dressing base readily emulsifiable with egg in the presence of aq. material to produce a smooth homogeneous product contains spices as customarily used in salad dressings together with an emulsifying agent such as gum tragacanth or gum arabic and a salad oil.

Tea and coffee for beverage preparation. Clarence G. Lehr. U. S. 2,169,957, Aug. 15. Material such as tea or roasted coffee is pulverized and mixed with (suitably about 30%) of freshly pptd. $Fe(OH)_3$ and the mixt. is further dried and ground, the treatment serving to render insol. the tannic acid present.

Poultry feed. Bernard Jurale. U. S. 2,170,562, Aug. 22. For preventing cannibalism of poultry, a supplemental feed is used having an ingredient of a high keratin content, such as a mixt. of charcoal, molasses and ground cattle horn.

Iodide - containing salt blocks for stock feeding. Douglas S. See (to Leslie-Calif. Salt Co.). U. S. 2,170,611, Aug. 22. Salt blocks are prepd. contg. KI dissolved in a viscous sugar sirup (suitably with conjoint use of Fe oxide, $MgCO_3$ and $MgCl_2$).

13 CHEMICAL INDUSTRY AND MISCELLANEOUS INDUSTRIAL PRODUCTS

(PLASTICS, RESINOIDS, INSULATORS, ADHESIVES, ETC.)

HERMAN A. BRUSON

Filtering media used in gas masks. Mario Sartori. *Chimica e industria* (Italy) 21, 537–41(1939).—Tests on gas masks currently in use show that all have a fibrous material as base, either cellulose or wool fiber. The masks which have a wool fiber base outlasted the masks which have a cellulose base. A. W. Contieri

A case of intracorpuscular sulfhemoglobinemia resulting from occupational nitrobenzene poisoning. Enrico C. Vigliani and Giovanni Donati. *Rass. med. ind.* 10, 534–51 (1939).—Nitrobenzene poisoning as observed in a workman engaged in polishing metals and cleaning metal filters with the hot liquid is described, with clinical data of blood tests, erythrocytometric formulas (table) and a graph showing the erythrocytometric curves. The symptoms were those of intense cyanosis, anemia, mental disorders, etc., combined with intracorpuscular sulfhemaglobinemia, produced by the combined action of the nitrobenzene and the sulfonated H_2 formed by the hydrolysis of the org. S compds. contained in the vulcanized rubber in the metal filters. 12 references. A. H. Krappe

Mechanism of development of lead anemia. IV. The physicochemical nature of the splenic and liver substances which decrease erythrocytes. Syosei Kin. *J. Med. Coll. Keijo* 9, 101–17(1939).—K. found that the spleen and liver contain some specific chem. substances able to decrease erythrocytes after the injection of sugar of lead. He tried to clarify the physicochem. nature of these substances, which were obtained from the splenic and liver vein of the animals after injection of sugar of lead. The anemic action of the splenic substance disappeared after heating an hr. at 100°. The substance was water-sol., but did not dissolve in ether and alc., it was not adsorbed by animal charcoal or kaolin. The effect of the liver substance disappeared after heating an hr. at 100°. This substance was sol. in water and did not dissolve in ether and alcohol, but it was adsorbed easily by animal charcoal or kaolin. The action of this substance was also retained after ultraviolet radiation for 3 hrs. I. S. Yun

Properties of high-strength molded articles from synthetic resins. A. Thum and H. R. Jacobi. *Z. Ver. deut. Ing.* **83**, 1044–8(1939).—Discussion of the properties of airplane parts with fabric base and contg. 30–50% PhOH-CH_2O resin: cold flow and creep, effect of rate of loading, deviation from Hooke's law and strength under repeated stresses (flexing). Arnold M. Collins

Bearings of synthetic resins. Ch. Berthelot. *Rev. ind. minérale* **444**, 325–32(1939).—The bearings are composed of celoron, which consists of cloth impregnated hot with synthetic resins - azolone, bakelite, gedelite, progelite, etc.—and subjected to pressure. The cloth is of a coarseness depending on the purpose to which the bearing is to be put—very fine for a bearing for clockwork, very coarse for one for a roller. A sample of celoron has d. 1.4, Brinell hardness 45, rupture strength 7 kg./sq. mm., compression strength 21–28 kg./sq. mm., coeff. of dilatation 0.00001 per degree, coeff. of friction 0.02–0.03 for velocities above 0.2 m./sec.; water is the best lubricant. C. A. Silberrad

Preparation of modified resins by the use of fatty derivatives. Anderson W. Ralston. *Oil & Soap* **16**, 215–18(1939).—The theory of resin formation is discussed as shown by polymerization, condensation or a combination of the two. Fat acid derivs. can be employed for the prepn. of resins which possess distinctive properties such as flexibility. Resin-forming compds. such as styrene, coumarone, indene and phenol can react with fat acid chlorides of high mol. wt. in the presence of $AlCl_3$ to produce acylated compds. which can then be polymerized by heat or catalysts to give resins. These resins possess properties dependent upon the degree of acylation and the type of acyl group which is introduced. Thus there are the styrene, coumarone and indene resins, also Glyptal and phenol-aldehyde resins. In all of these types the long alkyl group is incorporated into the resin structure and the plasticizing agent is an integral part of the resin itself. Whenever these long acyl groups are introduced into a resin formula the resulting product is more flexible than the unmodified resin. E. Scherubel

Acrylic resins. D. S. Frederick. *Modern Plastics* **17**, No. 2, 22–4(1939).—A review. E. H.

Denture base material: acrylic resins. W. T. Sweeney. *J. Am. Dental Assoc.* **26**, 1863–73(1939).—Tests of 3 acrylic resins indicated that they compare favorably with vulcanite in nearly all mech. properties of dental significance, are superior to rubber in ease of curing and in esthetic properties, are color-stable under oral conditions and are as serviceable as rubber in dentures. In the partially polymerized (plastic cake) condition, the material has a short shelf life at room temp., but may be stored satisfactorily for several months at a temp. of 5°, while the liquid and the powder have a shelf life of more than 1 yr. at room temp. Joseph S. Heyburn

Vinyl ester resins. G. C. Miller. *Modern Plastics* **17**, No. 2, 182, 184, 186(1939).—A review. E. H.

Wetting and spreading properties of aqueous solutions. Mixtures of sodium carbonate with caproic, caprylic, capric, lauric, myristic and palmitic acids. H. L. Cupples. *Ind. Eng. Chem.* **31**, 1307–8(1939); cf. *C. A.* **31**, 6763[3].—The surface tension, interfacial tension against mineral oil and spreading coeff. of mixts. of Na_2CO_3 with 1% solns. of caproic, caprylic, capric, lauric, myristic and palmitic acids are detd. and plotted against Na_2CO_3-fatty acid mol. ratio. Relative positions of the curves correspond approx. with the order of increasing mol. wt. of the fatty acids. Compared to NaOH mixts., Na_2CO_3 mixts. with oleic and with lauric acids give lower surface and interfacial tensions. With the other fatty acids Na_2CO_3 has only a slight advantage. From characteristics in the surface-tension curves Na_2CO_3 is considered to react as a diacid base with the more highly ionized lower fatty acids and as a monoacid base with the weaker acids of higher mol. wt. A. J. Stirton

Spots versus spot removers. C. A. Taylor. *Glass Packer* **15**, 696–7, 715, 724(1937).—The use of $CHCl_3$, CCl_4, $CHCl.CCl_2$, $C_6H_5CH_3$, various oxidizing agents and saponifiers for cleaning purposes are discussed. C. R. Fellers

Problems concerning the efficiency of oils as mosquito larvicides. II. The spreading power of oils and methods of increasing it. David R. R. Murray. *Bull. Entomol. Research* **30**, 211–36(1939); cf. *C. A.* **33**, 8855[4].—Pure higher paraffins are nonspreading; pure aromatic compds. have only small spreading pressure. Com. petroleum oils owe their spreading properties to the presence of small quantities of impurities. Spreading power is increased by irradiation of very thin layers of oil; a very small fraction of the oil undergoes chem. change by this treatment. Straight-chain fatty acids and ales. increase the spreading pressure of clean oil to a value already attained in the crude oil. Compds. in which a simple group such as -OH is attached to the right hydrocarbon framework will increase the spreading pressure of an oil. E. g., $-SO_3OH$ at the end of simple hydrocarbon (particular one not indicated) was more effective than any other grouping investigated. Water-sol. substances are not good spreaders because they dissolve out of the oil. The max. spreading pressure exerted by a substance in oils is greater in paraffin than in aromatic oils. When oil is shaken with a solvent which sepd. aromatic compds. from paraffins, the spreading constituents pass into the aromatic fraction. In this way strong concns. can be obtained, and the active substances can be transferred from one oil to another. Spreading constituents are entirely removed from petroleum oil by filtration through fuller's earth. C. H. R.

A new mosquito-larvicide oil. M. Kubo and Eiziro Ohito. *J. Oriental Med.* **31**, 407–9 (English abstr. 36)(1939).—A new mosquito-larvicide is an equal mixt. of "Dapus oil" and "Leave oil" (by-products of oil-shale distn.), 1 l. per 1.5–2 acres being suitable for rice field and more being required for ponds and marshes. It kills the larva in 1 day, injures other rice plant insects, but is harmless to the plant. S. Tashiro

---

Subjecting liquids to sound vibrations for prepg. emulsions (U. S. pat. 2,170,178) 1.

Couillaud: Gaz de combat. Propriétés chimiques et physiologiques. Protection thérapeutique des intoxica-

tions. Essai de contribution à la défense passive. 2nd ed. Paris: J.-B. Baillière. 175 pp. Fr. 32.

Respirators for use in dust- or smoke-laden atmospheres. B. F. McDonald Co. Brit. 506,168, May 23, 1939.

Packaging plastic materials such as "dentocoll." Clyde A. Nelson. U. S. 2,171,708, Sept. 5. A stick of semirigid "reversible hydrocolloid" such as the dental impression material "Dentocoll" is provided with a loosely fitting flanged ring intermediate the ends of the stick and with end-closures formed from latex and engaging the rim.

Mixed esters of dicarboxylic acids. Carl J. Malm and Charles R. Fordyce (to Eastman Kodak Co.). U. S. 2,170,030, Aug. 22. Mixed esters (suitable for use as *plasticizers* with cellulose acetate, etc.) such as ethylene glycol diethyl and dimethyl diphthalates, hydroquinone diethyl diphthalate, ethylene glycol diethyl disuccinate, glycerol trimethyl triphthalate, and hydroquinone dimethyl disuccinate are produced from the acid dicarboxylic acid esters of polyhydroxy compds. prepd. as described in U. S. 2,023,485 (*C. A.* **30** 732) by reaction with alcs. such as MeOH or EtOH to esterify the remaining carboxyl group. Various details of the production and use of these plasticizers are given.

Apparatus for loosening moldable or plastic material from its support after a drying, hardening or curing process. Horace Allan Wilkinson. Brit. 506,833, June 6, 1939.

Apparatus for molding plastic material, as in forming transmission belts. Edward L. Schick (to B. F. Goodrich Co.). U. S. 2,172,111, Sept. 5. Various structural, mech. and operative details.

Molding transparent resin compositions. Richard F. Warren. U. S. 2,169,825, Aug. 15. In forming articles such as phonograph records, a transparent resin compn. such as one of a vinyl resin is molded, then printed upon, and then further molded with heating to draw the resin over the printing.

Molding lenses, etc., from synthetic resin. Raoul Fritz. Brit. 505,836, May 15, 1939. Optical lenses and prisms are molded from transparent thermoplastic org. substances, e. g., vinyl or acrylic esters, in molds of glass or quartz.

Producing patterned articles such as buttons from molding powders such as "artificial horn." Hans Schafer. U. S. 2,170,931, Aug. 29. A method of producing patterned objects, having the pattern extending throughout the thickness of the object from face to back from molding powders of all kinds, color and granulation, involves introducing by centrifugal action, in a cylindrical mold, successive concentric layers of the powders, each of a different color, and compressing the layers longitudinally; removing the so-formed object from the mold and then applying lateral pressure transversely to the axis of the layers to form an oval coherent body.

Quick-curing resin-fiber composition suitable for molding sheets, etc., with use of heat and pressure. Norman D. Hanson (to Bakelite Corp.). U. S. 2,170,755, Aug. 22. A quick-curing product is prepd. by treating a sheeted mixt. of a fibrous material such as kraft pulp and about 15-40% of a phenol-aldehyde resin in which the reaction was approx. to the gel point, with 5-25% of a free-flowing, quick-curing phenol-aldehyde resin.

Synthetic resinous products. Geo. F. C. Houghton. U. S. 2,172,385, Sept. 12. A resinous compn. comprises in chem. combination a condensation product of a phenol and an aldehyde having incorporated with it 20-30% of rubber together with polymerized vinyl chloride or vinyl acetate; it is capable of being cast or molded under applied heat to a solid having both thermosetting and thermoplastic properties.

Urea-formaldehyde resins. Oskar R. Luddwig (to Resinous Products & Chemical Co.). U. S. 2,171,882, Sept. 5. A process of producing condensation products from urea and formaldehyde comprises heating a nonacidic mixt. of butanol, one mol. equiv. of urea and at least 2 mol. equivs. of aq. formaldehyde until the reaction has at least reached the methylol urea stage, adding to the soln. approx. 0.06% of formic acid based on the anhydrous wt. of the starting materials and refluxing for from ½ to 1 hr., reducing the pressure to a point at which the mixt. will boil at a temp. below 80°, distg. substantially all the water from the mixt. while the butanol also vaporized is replaced, releasing the vacuum and continuing the distn at atm. pressure until a total of approx. 2 mols. of water of reaction separated for each mol. of urea condensed. Products thus prepd. are suitable for use in coating metals, etc.

Resins from phenolic compositions and esters of anacardic acid. Emil F. Novotny (to Durite Plastics, Inc.). U. S. 2,170,950, Aug. 29. A synthetic resin such as a phenol-aldehyde resin or a natural resin such as gum accroides is caused to react (suitably by heating up to about 285°) with crude anacardic ester such as the Me, Et, Am, Bu, Pr or iso-Pr esters which may be derived by esterifying cashew nut-shell liquid, the resulting products being suitable for use in coating compns., adhesives, fabric-impregnating and molding compns., for phonograph records, abrasive wheels, brake linings, elec. insulation, printing plates, etc.

Heat reactive oil-soluble resins suitable for coatings or molded products. Wm. H. Butler (to Bakelite Corp.). U. S. 2,171,914, Sept. 5. By the reaction of a trialkyl phenol such as a trimethylphenol and a methylene-contg. substance such as CH_2O (suitably in the presence of $(CH_2)_6N_4$) there is obtained a heat-reactive resinous material substantially free from components volatile under vacuum at 110° and sol. in drying oils to produce a compn. hardening with heat more rapidly than the drying oil alone.

Resinous condensation products. Israel Rosenblum U. S. 2,169,991, Aug. 15. Products suitable for use with varnish oils are obtained by treating 1 mol. of a phenolic compd. such as amyl phenol with at least 2 mols. of CH_2O and approx. 1 mol. of glycerol until a viscous condensate is obtained and then neutralizing excess glycerol with an acidic natural resin such as rosin.

Oily to resinous condensation products suitable for use with various solvents. Adolf Weihe (to Deutsche Celluloid Fabrik). U. S. 2,171,965, Sept. 5. CH_2O or AcH is treated with iso-Bu carbamate or other ester of a carbamic acid with an alc. contg. more than 2 C atoms at a temp. above about 80° in the presence of a compd. of acid reaction such as HCl. Numerous examples are given.

Stabilizing polymeric vinyl resin coatings on metals. Geo. H. Young (to Stoner-Mudge, Inc.). U. S. 2,169,717, Aug. 15. Coatings such as those of polymerized vinyl chloride and vinyl acetate are rendered more stable to heating by admixture with a small proportion of quinine or other cinchona alkaloid.

Uniting materials such as resin-coated film and paper. Clyde Scott. U. S. 2,171,259, Aug. 29. App. is described, and a method of laminating nonfibrous film to base material, comprising the steps of feeding nonfibrous film having at least one thermo-adhesive surface directly from a supply roll between two pressure-applying rollers; feeding base material from a supply roll into contact with the thermo-adhesive surface of the film between the pressure-applying rollers; applying heat to the film sufficient to render the thermo-adhesive surface directly adhesive, and at the same time applying rigid pressure and resilient counter pressure in opposed relation to the nonfibrous film and the base material to render the adhesive surface of the nonfibrous film adherent to the base material.

Making dentures of materials such as vulcanite, and synthetic resins. Charles S. Pallard. U. S. 2,171,736, Sept. 5. App. is described, and a process of making dentures which includes the steps of encasing a denture model of wax or the like with a foil having form-sustaining characteristics when later brought into contact by a molten metal, pouring molten metal about such foiled model to form, when the metal sets, a separable mold consisting almost entirely of metal, wherein the teeth of the model are held in their relationship as fixed in the model, removing the model material, which has been melted by the heat of the molten metal, and applying heat to denture-forming

material placed within the mold by conduction through the mold. Pb foil may be used.

Electrical insulation. Wm. R. Scigle (to Johns-Manville Corp.). U. S. 2,170,434, Aug. 22. A compressed and hardened elec. insulator sheet suitable for elec. switchboard panels comprises cement, asbestos fibers serving as a reënforcement, and paraffin, Zn stearate or Al stearate serving as a water-repellent agent in a proportion of about 1–3%.

Electrical insulation. Raymond M. Fuoss (to General Elec. Co.). U. S. 2,171,334, Aug. 29. Elec. insulation suitable for use on conductors and with stable elec. losses at elevated temps. comprises a plasticized polymerized vinyl halide and Pb resinate.

Electrical insulating composition suitable for use in transformers, etc. Arthur A. Levine and Oliver W. Cass (to E. I. du Pont de Nemours & Co.). U. S. 2,171,855, Sept. 5. A mixt. of chlorinated iso-Pr benzenes b. 260–310° is used with a diluent mixt. of chlorinated iso-Pr benzenes b. 250–260°.

Insulation in electron-discharge devices. Delos H Wamsley (to Radio Corp. of America). U. S. 2,171,230, Aug. 29. Insulating material such as mica spacers is provided with a coating of alumina monohydrate of a thickness of at least 0.005 in., which serves to reduce secondary emission and leakage.

Insulation for electric heaters. Frank Kuhn and Laurence H. Thomas (to American Electrical Heater Co.). U. S. 2,171,879, Sept. 5. Layers of mica and magnesia are used between a resistor and a surrounding sheathing, with the mica layer in contact with the resistor.

Insulating material suitable for electrical coils, etc Raymond P. Lutz (to Western Elec. Co.). U. S. 2,172,445, Sept. 12. See Brit. 492,420 (*C. A.* **33**, 1839⁶).

Electric apparatus for determining insulating values of various materials. Frank C. Doble and Glenn H. Browning (to Doble Engineering Co.). U. S. 2,170,813, Aug. 29. Various elec. and operative details.

Heat-insulation wall. Fred G. Johnson (to United States Gypsum Co.). U. S. 2,172,048, Sept. 5. Various structural details of walls provided with parallel spaced sheets of heat-reflective material such as Al foil with an intermediate filling of light porous material such as glass wool.

Apparatus for demonstrating the effectiveness of heat insulation. Robert Waldo (to American Flange & Mfg. Co.). U. S. 2,172,229, Sept. 5. Various structural details of a device with a heater and thermometer, between which the material under test is placed.

Clay products such as light-weight heat and sound insulation. Floyd B. Hobart (to Battelle Memorial Institute). U. S. 2,171,290, Aug. 29. A method of making a ceramic product comprises making a suspension of ceramic material in water to effect gelation of a sol. silicate to be subsequently introduced and wherein the suspension has a pH value suitable for attainment of gelation at a desired time, and adding the sol. silicate in powdered form to bring about gelation and consequent conversion of the suspension from a liquid to a solid phase.

Cellular products such as sound and heat insulation. Richard C. Thompson (to F. E. Berry, Jr. & Co.). U. S. 2,170,102, Aug. 22. A granular filler such as limestone and powd. glass is mixed with an aq. alkali silicate soln. and the mixt. is beaten to aerate it and form a foamy, cellular liquid of predetd. increased volume which is then immediately heated at a relatively low temp. to dry it to a solid cellular condition, followed by further drying at a higher temp.

Cellulose pads or bats for use as heat and sound insulation. Charles A. Fourness (to Paper Patents Co.). U. S. 2,170,655, Aug. 22. A bulky, porous, multi-ply pad or bat suitable for use as an insulating material comprises a plurality of superposed, thin, creped, cellulosic sheets each of which contains from 10% to 50% of an asphalt which is relatively brittle at room temp., and which has a m. p. of 60–93°, the asphalt being in the form of small, discreet particles of widely varying dimensions, and substantially all of the particles being individually attached to individual fibers or groups of the fibers making up each of the sheets, whereby the individual fibers in the pad or bat are unequally loaded or weighted, the pad or bat having a stable d. under ordinary mfg. conditions within the range of 1.25 to 2.00 lb. per cu. ft.

Self-setting compositions for heat and sound insulation. Dorothy H. Grunwald. Brit. 506,134, May 23, 1939. These consist of a slurry of $CaCO_3$ and $MgCO_3$ prepd. by carbonation of a suspension of calcined dolomite and removal of excess H_2O, e. g., by decantation. The $MgCO_3$ is obtained as fine crystals by carbonation at about 20–40° with agitation, excess CO_2 being avoided so that no $Mg(HCO_3)_2$ is formed. The setting is accelerated by heating of the molds, preferably to 60–90°. After setting, the products are removed from the molds and dried at 70–200°. Fillers, e. g., asbestos, diatomaceous earth, may be incorporated in the slurry.

Halogenated organic compounds such as those used for insulating. Frank M. Clark and Walter M. Kutz (to General Elec. Co.). U. S. 2,169,872, Aug. 15. Solidification of materials such as chlorinated biphenyl, etc., is inhibited by adding 10% or more of tetrachlorobenzene.

Insulating magnetic particles such as those used for loading coils. Victor E. Legg (to Bell Telephone Laboratories, Inc.). U. S. 2,169,732, Aug. 15. App. is described, and a method of insulating magnetic dust particles such as those of "permalloy" carried in suspension in a liquid medium such as water and maintained in suspension by agitation, which involves directing the material through a zone of restricted cross-sectional area, in admixt. with an insulating material such as a mixt. of colloidal clay, Na silicate, $Mg(OH)_2$ and water while the materials are subjected to trains of compressional elastic waves of high frequency, and the particles are subsequently dried.

Forming coatings of insulating material on metallic surfaces. George S. P. Freeman. Brit. 506,046, May 22, 1939. The surface is oxidized, a layer of insulating material that will wet the oxidized surface is evapd. thereon and the coating is then baked at a temp. near the m. p. of the insulating material. The process may be used for the production of a mosaic electrode for television transmission. As an example, Li borate is evapd. *in vacuo* onto the oxidized surface and the coating vitrified by stoving of the article for a few sec. in an inert atm. at about 10° above the m. p. of the borate.

Liquid dielectric compositions suitable for use in transformers, etc. Gerald H. Coleman and Luther F. Berhenke (to Dow Chemical Co.). U. S. 2,169,995, Aug. 22. A halogenated diphenyl oxide contg. at least 4 atoms of halogen per mol., such as a hexachlorinated diphenyl oxide, is used with a substantial proportion of an alkylated diphenyl oxide having an av. of not more than 4 alkyl groups per mol.

Alkylated diphenyl oxide derivatives. Gerald H. Coleman and Ralph P. Perkins (to Dow Chemical Co.). U. S. 2,176,809, Aug. 29. Products suitable *for use as dielectrics in transformers*, condensers and other elec. app. or as plasticizers with resins and varnishes, etc., are prepd., e. g., by treating an alkyl halide, an olefin, or an alc. other than EtOH with diphenyl oxide in the presence of a catalyst of the Friedel-Crafts type, so as to obtain diisopropyldiphenyl oxide, b. about 158–9° or an alkylated mixt. comprising butyl- and poly-butyl-diphenyl oxides as main constituents. Numerous examples with details are given.

Pressure-sensitive adhesive sheets. Ralph T. K. Cornwell (to Sylvania Industrial Corp.). U. S. 2,171,140, Aug. 29. A pellicle of nonfibrous cellulose hydrate, alkali-sol. cellulose ether or insolubilized gelatin is provided with a pressure-sensitive rubber adhesive coating and with an intermediate coating of gelatin, glue, dextrin or casein in the form of a hydrogel simultaneously formed *in situ* with the rubber coating. Such a material is suitable for use in the manuf. of various laminated products.

Adhesive compositions for sheets of paper, cloth, etc. Willard L. Morgan (to American Maize-Products Co.). U. S. 2,170,273, Aug. 22. Adhesives retaining their flexibility and not becoming hard or brittle comprise an aq. soln. of a water-sol. protein adhesive such as glue,

gelatin or casein and borax, together with a water-sol. aliphatic alkylolamine lactate such as triethanolamine lactate, monoethanolamine lactate or diethanolamine lactate.

Adhesive masking tape. John O. Doty and Paul C. Orcutt (to Minnesota Mining & Mfg. Co.). U. S. 2,171,544, Sept. 5. An adhesive tape is prepd. by providing a flexible backing material such as paper and mixing together a compn. contg. a rubber-base material insol. in the presence of water or the usual solvent vehicles employed in paints and varnishes, forming it into a layer, preforming one surface, as by polished rollers, and moistening the layer compn. on the opposite surface with a solvent such as benzene and then applying it as a thin film to the flexible backing by pressure.

Adhesive sheet material suitable for wrapping foods, tobacco, etc. Willard L. Morgan (to Sylvania Industrial Corp.). U. S. 2,170,949, Aug. 29. Rubber adhesives contg. a resin and used on wrapping tapes or sheets are rendered free from disagreeable odor by mixing with 1% or less of phthalic acid. Various formulas of adhesives are given.

Adhesive-coated paper suitable for gummed tape. Harold R. Dalton (to Postal Telegraph-Cable Co. (New York)). U. S. 2,170,654, Aug. 22. Roll paper is provided on one side with a layer of hygroscopic water-sol. adhesive and over the adhesive is superposed a slightly tacky protective layer of dextrin with which is mixed a relatively small proportion (suitably about 0.5-1.0%) of starch.

Salts of cellulose ether carboxylic acids. Georg Meyer. U. S. 2,171,222, Aug. 29. For the prepn. of salts of cellulose ether, carboxylic acids such as those for an adhesive size, which, with water, yield solns. of increased viscosity, the reaction product obtained by the action of a monohalogen fatty acid such as monochloroacetic acid on alkali cellulose is pptd. with an Al compd. such as alum and the ppt. is washed with water and converted into a water-sol. salt with an alkali such as soda lye.

Glue compositions Curt Schulein. Brit. 505,868, May 18, 1939. Finely ground straw is added as a diluent and improving agent to animal glue, particularly for veneer work. Finely powd. inorg. substances, e.g., dolomite, calcined dolomite, $CaCO_3$, kaolin, calcined gypsum, stone dust, slate dust, may also be added.

Sulfonic acids for use as textile assistants. Hermann Holstein (to I. G. Farbenind. A.-G.). U. S. 2,170,380, Aug. 22. Products suitable for use as assistants in processes such as textile treatments are produced by heating an alkali metal salt of sulfurous acid with the Na salt of octadecyl alc. sulfuric ester or other sulfuric ester of an aliphatic primary alc. contg. at least 8 C atoms, at a temp. of 100-250°. Several examples with details are given.

Sulfonic acids and their salts. Walther Schrauth and Eric Schüm (to "Unichem" Chemikalien Handels A.-G.). U. S. 2,171,117, Aug. 29. For producing a sulfonic acid for use in textile treatments, etc., a sulfuric acid ester of a higher-mol. alc. such as cetyl alc. is treated with NaOH to form a Na ester salt and then with a Na or K compd. to obtain the salt of the sulfonic acid, which may then be further treated to obtain the free sulfonic acid. Also a bromide such as cetyl bromide may be dissolved in 70-80% alc. contg. NH_4 sulfite in soln. (about 3 times as much alc. as bromide is used) and this mixt. may be heated to about 120-4° in an autoclave to convert the bromide to a salt of sulfonic acid.

Sulfocarboxylic acid esters suitable as assistants in the textile and related industries. Fritz Guenther and Karl Saftien (to I. G. Farbenind. A.-G.). U. S. 2,169,998, Aug. 22. Oleyl sulfoacetate and other esters are produced which are suitable for use as cleansing and emulsifying agents and which have the general formula RCOOR′ in which R represents an aliphatic radical contg. up to 7 C atoms and at least one sulfonic radical, and R′ represents a radical of an aliphatic alc. obtainable by reduction of the unsatd. fat acids of vegetable oils and fats.

Benzimidazoles. Charles Graenacher and Jules Meyer (to Soc. pour l'ind. chim. à Bâle). U. S. 2,170,474, Aug. 22. *Wetting, emulsifying, dispersing, purifying, washing, softening* and *foaming agents* are produced by reaction of benzaldehyde, cinnamaldehyde, formaldehyde, lauraldehyde or other aldehydes upon a cyclic amidine of which the μ-C atom carries a substituent consisting of a chain of at least 2 C atoms, wherein the α-C atom is present in the form of a methylene group (this chain being interrupted if desired by a S or a N atom), such as μ-heptadecylbenzimidazole or μ-ethylbenzimidazole. The products may be sulfonated or reduced or alkylated or aralkylated (the latter operation being carried out to the formation of tertiary bases or to the formation of quaternary NH_4 compds.) and these various treatments may be combined with each other, e. g., after condensation with the aldehyde (which may be effected by heating in the presence of boric acid) the product may be first alkylated and then sulfonated or reduced, or first reduced and then alkylated and finally sulfonated. Numerous examples with details are given. Cf. *C. A.* **33**, 1064⁴.

Stable emulsions for sizing and waterproofing. Otto Kress and Charles E. Johnson (to Institute of Paper Chemistry). U. S. 2,172,392, Sept. 12. A method of prepg. a stable emulsion involves adding a liquid waxy material such as paraffin accompanied by agitation to an aq. alk. soln. contg. milk casein and an emulsifying agent such as NH_4 oleate (the casein being present in such quantity relative to the waxy material that the particles thereof are surrounded by a protein film preventing agglomeration of the waxy particles when the emulsion is broken by addn. of acidic material; the ratio of casein to wax is at least about 1:4).

Condensation products suitable for use in tanning or for rayon treatment. Ernst Koch, Christoph Thomsen and Karl Dachlauer (to I. G. Farbenind. A.-G.). U. S. 2,171,963, Sept. 5. By condensing a natural resin such as colophony with a phenolic compd. such as phenol or cresol (suitably by heating in the presence of H_2SO_4 or H_3PO_4) a product is obtained contg. in its mol. the group $-CH_2-SO_3x$, where x stands for a H, an alkali metal or NH_4, and being further characterized by being a viscid to solid substance sol. in water.

Leatherlike surfaces on fabrics. Raymond C. McQuiston and Henry C. Hopewell. U. S. 2,172,028, Sept. 5. A bonding material such as a rubber compn. is applied to fabric, and dry ground leather is deposited continuously on the surface to adhere to it; and the leather is satd. and the interstitial spaces between the leather fibers are filled with a soln. contg. tannable protein materials such as a glue or gelatin compn. and these materials are tanned after satn (suitably by use of a CH_2O soln.).

Fabric-reinforced 'artificial leather" suitable for use in shoe manufacture, etc. Milton O. Schur and Benjamin G. Hoos (to Brown Co.). U. S. 2,171,419, Aug. 29. A felt layer impregnated with rubber latex, etc., is bonded to a cloth reinforcement also impregnated and whose threads have been flattened and compressed markedly and whose face coming into contact with the felt layer has been napped.

Lacquer coatings on materials such as textile fabrics or leather. Steven J. B. ten Cate. U. S. 2,171,389, Aug. 29. A process of providing flexible materials with a coating of lacquer comprises applying to the material at least one priming layer contg. a large quantity of fillers and rubber as the only binder and at least two intermediate layers consisting of a mixt. of a rubber dispersion, a polymerized acrylic acid ester and a cellulose ether emulsion, the first intermediate layer contg. a larger proportion of rubber than the succeeding intermediate layers so as to obtain a firm adherence of the first intermediate layer to the rubber base and of the last intermediate layer to the cellulose lacquer coating, and subsequently applying a coating of cellulose lacquer.

Polymerization products from materials such as polyamides derived from ethylenediamine and sebacic acid or the like. Paul J. Flory (to E. I. du Pont de Nemours & Co.). U. S. 2,172,374, Sept. 12. A process for producing a more highly condensed polymer from a lower-mol. wt. polyamide obtainable from approx. equimol. proportions of

diamine and dibasic acid comprises heating the polyamide at polymerizing temp. below its m. p. under conditions permitting escape of the by-product of the condensation reaction, and continuing such heating until the more highly condensed polymer is formed. Polymers thus prepd. are suitable for making films, filaments, fabrics, molded articles, etc.

Polymers of isobutylene. Michael Otto and Helmuth G. Schneider (to I. G. Farbenind. A.-G. and Standard Oil Development Co.). U. S. 2,172,403, Sept. 12. For producing viscous to plastic polymers of good stability, a highly purified isobutylene is subjected to catalytic polymerization, at a temp. below −40° in the presence of less than 1% of a S compd. such as H_2S.

Polymerizing methyl methacrylate. Otto Röhm and Ernst Trommsdorff (to Röhm & Haas Co.). U. S. 2,171,765, Sept. 5. A process of prepg. a polymeric ester of methacrylic acid in granular form involves forming by means of mech. agitation unaided by any emulsifying agent an aq. suspension of a finely divided polymeric methacrylic ester and an amt. of monomeric methacrylic ester at least ten times as great as that of the polymeric ester, subjecting the continuously agitated suspension to polymerizing influences until polymerization is complete, and discontinuing the agitation to permit settling of the polymeric material.

Distilling polymerizable materials such as vinyl or acrylic esters. Carl T. Kautter (to Röhm & Haas Co.). U. S. 2,171,795, Sept. 5. An arrangement of app. is described, and a process which comprises subjecting to fractional distn. a member of the group consisting of monomeric vinyl, acrylic and methacrylic esters, acrylic and methacrylic nitriles and styrene by feeding the monomeric material into the lower half of a fractionating column, feeding a phenol having a higher b. p. than the monomeric material into the column near the top thereof, the two liquids being fed at such rates that the phenol is about 5% to 12% of the total material in the column and heating the monomeric material, thus causing the vapors to pass upward through the column against a downward flowing stream of the phenol.

Polishes. Robert Easten and Noel Shaw. Brit. 506,771, June 5, 1939. Surfaces of porous structures or articles are polished by application thereto of a layer of a liquid that leaves a hydrated SiO_2 deposit, and subsequent rubbing of the layer into the surface in the manner of French polishing. A suitable liquid is formed by causing an ester, or mixt. of esters, of silicic acid to react with H_2O in the presence of a solvent for the ester that can carry H_2O in soln. or suspension, e.g., alc., Me_2CO, toluene.

Fluid polishing compositions. Boston Blacking Co., G. m. b. H. Brit. 506,425, May 26, 1939. These comprise an aq. liquid vehicle having suspended therein wax particles that have been comminuted, prior to embodiment in the compn., by spraying wax in a liquefied state into an atm. in which the spray particles solidify. The comminuted wax may be colored by means of an oil color, and the polish may include, in addn. to the comminuted wax particles, wax emulsified in the liquid vehicle. A thickening agent may be added. In an example, a polishing compn. comprises comminuted wax, H_2O, an aq. wax emulsion, shellac, dye, sea moss or mucin, and soap.

Bonding and coating compositions suitable for use in linings for acid-pickling tanks, etc. Joseph C. Patrick (to Thiokol Corp.). U. S. 2,169,814, Aug. 15. S and a sulfurized pitch are used with reaction products of an alk. polysulfide and additive compds. of olefins of the general formulas $C_nH_{2n}X_2$ and $OC_nH_{2n}X_2$ in which X is a neg. radical such as Cl (a sufficient amt. of elemental S being present in the compn. to cause the viscosity to increase at elevated temps. in the absence of the pitch).

Coating compositions containing gelatin, etc. Charles M. Boyce (to John R. Ditmars). U. S. reissue 21,195, Sept. 5. A reissue of original patent No. 1,978,406 (*C. A.* 29, 366[7]).

Oil coatings for preventing evaporation of water, as in desert regions. Franklin C. Nelson (to Stanco, Inc.). U. S. 2,170,644, Aug. 22. For inhibiting evapn. from a surface, the surface is coated with a stable soln. of an alkyl phenol such as cresol or heptyl phenol in a satd. mineral oil, which is stable against oxidation and loss on exposure to the atm. and does not contaminate the water.

Chemical heating composition. Nathaniel W. Holmes and Samuel Parness. Brit. 507,070, June 8, 1939. A dry absorbent material, e. g., ground paper, 10 parts is impregnated with 1 part of a 50% soln. of $CaCl_2$, which may contain glycerol. Twenty parts of the impregnated mass is mixed with 1 of MnO_2. Another mixt. is made of finely divided Fe 8 and NH_4Cl 1 part, which is sprinkled with a 5% AcOH soln., the reaction yielding a dry mass. This mass is disintegrated and mixed with the 1st mixt. in equal proportions and packed into metal tubes circumferentially arranged in layers alternating with layers of paper pulp impregnated with $CaCl_2$.

Noncorrosive antifreeze liquid suitable for use in automobile engine cooling systems. Fred R. Whaley (to Carbide and Carbon Chemicals Corp.). U. S. 2,172,075, Sept. 5. With an alc. such as ethylene glycol, there is used a corrosion-preventive aromatic nitro-carboxy compd. having a nitro group directly attached to the aromatic nucleus, such as *p*-nitrobenzoic acid (suitably with $NaNO_3$, $NaNO_2$ and Na_2CO_3).

Brake and pressure fluids. Rudolf Endres. U. S. 2,171,491, Aug. 29. Tetrahydrofurfuryl alc. is used in mixt. with cyclohexanone-glycerol or ricinoleyl alc. or oleic alc. or castor oil (suitably with the addn. also of a small proportion of a high-mol. alkyl amine).

Friction linings for brakes and clutches. Rudolf Oswald. Brit. 505,922, May 19, 1939. These comprise a compressed compn. of Al, steel or other metal wool and a binder of artificial or natural resin, rubber or the like, with or without the addn. of asbestos fibers and powd. fillers.

Air strainer suitable for use with brake systems. Ellis E. Hewitt (to Westinghouse Air Brake Co.). U. S. 2,170,074, Aug. 22. Various structural details.

Laminated gaskets of materials such as sheet metal, asbestos and graphite. Geo. T. Balfe (to Detroit Gasket & Mfg. Co.). U. S. 2,171,530, Sept. 5. Various mfg. details and app. used are described.

Seamless tubing or hose. Robert A. Ramsdell (to E. I. du Pont de Nemours & Co.). U. S. 2,171,761, Sept. 5. Glycerol is applied to the fabric covering of a hose core, and a wet seamless tubing of nonfibrous cellulosic material is shrunk onto the surface of the core by removal of moisture from the tubing, and a rubber covering is vulcanized onto the outer surface of the tubing.

Inlaid articles such as fountain-pen barrels. Charles Schurster (to Nixon Nitration Works). U. S. 2,169,930, Aug. 15. A process of producing a body of plastic material such as a cellulose deriv. compn. having a pattern formed by a plurality of elements such as metal devices on its surface involves forming perforations in a metal tube or the like corresponding to the design desired, inserting the body in the tube and applying a solvent to the areas exposed through the perforations, applying decorative elements through the perforations, removing the tube, and applying a transparent sheath such as one of celluloid compn. to the body.

Collapsible tubes. "Hafta" Handelsgesellschaft für technische Neuheiten m. b. H. Brit. 507,130, June 9, 1939. A container consists of a transparent tube of a cellulose deriv. and a dispensing terminal fixed thereto, the inner surface of the container being provided with a film comprising a nonhardening artificial resin, e. g., polymerized vinyl ester or styrene, and a wax, e. g., beeswax. The tube may be of cellulose acetate and the terminal of "Bakelite." The container is preferably rinsed out with a soln. of the resin and wax in a solvent incapable of dissolving the walls of the container, and dried by hot air.

Printing surfaces. Alfred Schlesinger. Brit. 505,999, May 19, 1939. Zn, Al or other metal printing plates are treated to form on the image a uniform film of a nonresinous drying-oil compn. that is insol. in H_2O or printing ink and substantially insol. in the usual washing liquids. The compn. preferably contains a small proportion of a nondrying oil, e. g., castor oil, and an oxidation catalyst,

e. g., MnO_2, and preferably consists, in addn., of industrial alc., linseed oil and turpentine or C_6H_6. The plate, to which the image has been applied by transfer or photographic methods, is coated with gum which is then removed from the image area, a layer of the compn. being subsequently applied and the gum and overlying compn. finally removed. More than 1 layer of compn. with intervening layers of varnish may be applied; when varnish is applied, the upper layers of compn. may contain a small amt. of solvent for the varnish to facilitate binding. If the image consists of hardened albumin, the 1st layer of compn. is omitted. Adherence between the metal and compn. can be increased by treatment of the image with a nonaq. soln. consisting of alc. and NH_3 or $FeCl_3$ and an acid, to which $CaCl_2$ or sugar may be added to remove any H_2O present.

Toothbrush bristles. Warren E. Hill and Clifford L. McArthur (to Pro-Phy-Lac-Tic Brush Co.). U. S. reissue 21,197, Sept. 5. A reissue of original patent No. 2,099,688 (*C. A.* **32**, 312[9]).

Brushes. I. G. Farbenindustrie A.-G. Brit. 506,358, May 26, 1939. See Ger. 672,431 (*C. A.* **33**, 3934[9]).

Fiberizing inorganic materials. Benjamin C. McClure. U. S. 2,172,153, Sept. 5. App. is described, and a process of producing inorg. fibrous blankets of high inherent resiliency and mass integrity, suitable for insulation, which consists in fiberizing a fused soln. of silica with a fluxing ingredient and a stabilizing ingredient, to produce feltable fibers, and forming a felted product.

Resilient articles such as cushions or tires. Rene Picard (to E. I. du Pont de Nemours & Co.). U. S. 2,171,805, Sept. 5. Within a covering such as cloth or rubber, there is placed a filling comprising continuous threads of material such as regenerated cellulose of at least 100 denier contg. discontinuous bubbles filled with gas, the side walls of the thread surrounding the bubbles being sufficiently thin to make them readily yieldable and resilient.

Conditioning and humectant compositions for treating textiles, leather, tobacco, paper, glue, etc. Kenneth R. Brown (to Atlas Powder Co.). U. S. 2,172,357, Sept. 12. Sorbitol, iditol or talitol is used in a proportion of not more than 70% of the total solids of the compn. together with not more than 70% of the total solids of the compn. together with not more than 50% (similarly based) of branched-chain desoxy hexitols or pentitols, to avoid crystallization or gelatinization of the compn.

Products made from oyster or clam shell material or the like suitable for making buttons, etc. David A. Eolis (50% to Benjamin K. Ury). U. S. 2,172,369, Sept. 12. A mild process for treating shell materials composed of platelets held together by an org. binder to produce a fine powder consisting of platelets free from org. binder, possessing substantially their natural formation, polish and luster, involves dissolving away the outer layer of said shell materials with acid, crushing said cleaned shell material to a convenient size, substantially eliminating, after said acid treatment and crushing, all agitation or harsh treatment by immersing the thus treated shell material without further treatment, in an aq. soln. of a mild alkali, gradually increasing the temp. of said solution to between 25° and 100°, said increase of temp. being gradual enough to eliminate any eddy currents apt to be set up in said soln. from said heating, leaving said shell material at said temp. and at atm. pressure in said soln. with no agitation for a period of at least 3 weeks until said platelets are freed from said binder, gently washing said platelets with a minimum of agitation in water to free said platelets from any remaining impurities.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Tube-well water supplies of Assam and North Bengal. Henry A. C. P. Hetherington. *J. Inst. Civil Engrs.* (London) **9**, No. 8, 373–6(1938).—Water is available in large quantities and at comparatively shallow depths. Ann Nicholson Hird

Mineral waters of the Argentine Republic. V. Province of Jujuy. Miguel Sussini, Enrique Herrero Ducloux, Ramón A. Brandán, Héctor Isnardi, Alfredo G. Galíndez, Manuel Castillo and Franco Pastore. *Ministerio interior, Comisión nacl. climatol. y aguas minerales.* (Argentina) **1939**, 230 pp.; cf. *C. A.* **33**, 4355[7]. E. J. C.

The hot springs of Corniglio (Parma). Giuseppe Illari and Lino Cattadori. *Ann. chim. applicata* **29**, 289–95 (1939).—These are saline springs having a temp. of about 40°. A. W. Contieri

Chemical investigations of hot springs in Japan. II. Hot springs Noboribetsu. 2. Hisateru Okuno. *J. Chem. Soc. Japan* **60**, 685–91(1939); cf. *C. A.* **32**, 7175[8].—Observations on the 5 hot springs in Noboribetsu. T. Katsurai

Report on the comparative study of the density of city water and well water in Japan. Kokiti Goto. *J. Chem. Soc. Japan* **60**, 705–6(1939).—The d. of water from 9 various parts of Japan was detd. by means of a quartz hydrometer. The density is the same within ±0.5 γ. T. Katsurai

Report on the comparative study of the density of city water and well water in the world. Kenzo Okabe and Kokiti Goto. *J. Chem. Soc. Japan* **60**, 707–9(1939); cf. preceding abstr.—The densities of waters from 19 different parts of the world were detd. The d. is the same within ±0.5γ. T. Katsurai

Chemical and physical-chemical analysis of the mineral waters of Villa Gandolfi (Torino). Francesco Biglietti. *Ann. chim. applicata* **29**, 316–32(1939).—These springs are medium mineral bicarbonate-alk. earth waters. A. W. Contieri

Analysis of the mineral waters of Pieve di Cusignano (Parma). Giuseppe Illari and Stefano Beati. *Ann. chim. applicata* **29**, 212–19(1939).—These waters contain I_2, Sr, Ba and Mg in large amts., as well as traces of Li, HBr and HI. A. W. Contieri

Spectrum analysis of the Fonte di Fiuggi waters. Roberto Intonti. *Ann. chim. applicata* **29**, 205–12 (1939).—Spectrum analysis of the Fiuggi waters showed the presence of Ca, Mg, Si, Sr, K, Na, Mn, Cu, P, Fe, Cr and Ba in decreasing amts. in this order; and also traces of Zn, V, Sn, B, Al, Rb, Ag, Pb and Pt. A. W. Contieri

Correlation of various characteristics in a sanitary analysis of well water. W. T. Kuo. *J. Oriental Med.* **30**, 927–37 (English abstr. 263)(1939).—Statistical studies on the correlation of Cl, hardness, solids, bacterial count, turbidity, color, free and saline NH_3, and albuminoid NH_3, nitrate and O_2 of the well water of Mukden. S. T.

The use of hypochlorite in water analysis. F. Dixon and D. C. Jenkins. *Analyst* **64**, 735–6(1939).—Buydens, *C. A.* **29**, 6536[9], suggested that animal and vegetable org. matters can be differentiated by their relative behavior toward $KMnO_4$ and NaOCl. Expts. made with tap water to which peat, leaf mold and tea leaves were added to represent contamination with vegetables and urine and effluent were added to represent impurities of animal origin showed that in the first case the ratio of NaOCl to $KMnO_4$ consumption was 1-2.2:1 and in the latter case it was 7.4-8.4:1. In a more stringent test a soln. was prepd. from water to which a little dil. NaCl soln. in which bran had been soaked was added. This mixt. gave a pos. biuret reaction and the $KMnO_4$ demand was equal to the NaOCl demand provided the soln. was boiled 10 min. after the $KMnO_4$ was added. If the $KMnO_4$ treatment was carried out at 80° for 4 hrs. only 20% as much $KMnO_4$ was required which would have indicated the possible presence of animal matter. W. T. H.

Determination of sulfate in water by the volumetric chromate method. Jean Courtois and Pierre Bonjean. *Ann. chim. anal. chim. appl.* **21**, 229–35(1939).—Wilden-

stein (*Z. anal. Chem.* **1**, 323(1862)) pointed out the possibility of detg. sulfate on the basis of the reaction $BaCrO_4 + SO_4^{--} = BaSO_4 + CrO_4^{--}$. Since both $BaSO_4$ and $BaCrO_4$ are practically insol. in water, the chromate in soln. is a measure of the sulfate originally present. The method has often been studied and it is generally agreed that the results are invariably low and inconsistent. By modifying the procedure slightly, it is possible to det. 37–150 mg. of sulfate with an av. error of −3.5%. The modifications consist in adding a HCl soln. of $BaCrO_4$ to the boiling soln. contg. sulfate. After 5 min. the boiling is stopped and continued again after an interval of 15 min. Now the soln. is neutralized with NH_4OH until the soln loses its orange tint of $Cr_2O_7^{--}$. After this second boiling period of 5 min., the soln. is cooled and an aliquot taken for further analysis. To 100 ml. of the neutralized soln., 5 ml. of 25% H_2SO_4 is added and 5 ml. of 30% KI soln. After 10 min. more, the liberated I_2 is titrated with $Na_2S_2O_3$ soln. W. T. H.

Simplified water testing for plant operators. D. R. Hiskey. *Am. Gas J.* **151**, No. 4, 51–2(1939). E. H.

Fluoride content of well water in Manchuria. F. S. Chang. *J. Oriental Med.* **30**, 649–50(English abstr. 180) (1939).—Fluoride content of 14 samples collected from different regions of Manchuria varied from 1 to 12.5 parts per million according to the Foster method. S. Tashiro

The removal of fluorine from Alberta waters. Osman J. Walker, Gordon R. Finlay and Walter E. Harris. *Can. J. Research* **17, B**, 308–17(1939).—Numerous materials were studied in respect to their capacity for removing fluorides from water sufficiently to prevent mottling of the teeth. Two, specially prepd. Al_2O_3 and freshly pptd. $AlPO_4$, are equally good for removing fluorides as activated Al_2O_3, $Ca_3(PO_4)_2$ and MgO, 3 commonly used adsorbing agents. Good results were obtained by both the filtration and the stirring and standing technique. J. W. Shipley

Chemical-technical advances in the preparation of feed water. E. Schumann. *Chem.-Ztg.* **63**, 638–40(1939). E. H.

Feed [water] heating economies. F. J. Matthews. *Brit. Clayworker* **48**, 191–3(1939).—Corrosion is a more serious problem than deposition since substantial damage may be done before existence of the attack is suspected. In boiler plant operation the major part of any corrosive attack is caused by dissolved gases. These are CO_2 and O. The CO_2 combines with the metal to form a substance which is readily broken down by H_2O and heat to form rust and CO_2. At the end of a series of corroding actions the corrosive gas is regenerated. CO_2 may be removed by the addn. of lime or by heating the feed H_2O to boiling. E. C. Petrie

New viewpoints on the aggressiveness of water with practical examples. H. Mohler and J. Hartnagel. *Schweiz. Ver. Gas- u. Wasserfach., Monats-Bull.* **19**, 121–7, 147–50 (1939).—Aggressiveness of water is partly lime aggressiveness, partly iron aggressiveness. The former is discussed in the light of Strohecker's work (*C. A.* **31**, 1920[6]); the latter is a complex electrolytic problem. The present theories were applied on samples of ground water, lake water, and well water (Zurich). All waters had alk. pH, no aggressive CO_2 and development of iron bacteria. Even in the absence of aggressiveness, bacteria attacked the piping. After changes in water-supply system the free O_2 disappeared and in the presence of nonaggressive CO_2 the water dissolved Fe with formation of $Fe(HCO_3)_2$ which appeared as a brown ppt. in the presence of air. Aeration of the water corrected this condition. B. J. C. v. d. H.

Silica deposits in steam turbines. F. Kaissling. *Arch. Wärmewirt.* **20**, 89–91(1939).—Silica is removed from cold boiler feed water by addn. of equal mols. of $NaAlO_2$ and $MgCl_2$ and settling. The sludge may be recycled. Ernest W. Thiele

Improved oil-engine cooling. F. J. Matthews. *Brit. Clayworker* **48**, 220–1(1939).—Scale deposits are due to ecompn. of the bicarbonates under the influence of heat. The decompn. results in the formation of $CaCO_3$ which is practically insol. The formation of such carbonate deposits can be prevented by the addn. of 1 or 2 lb. of Na metaphosphate per 100,000 gal. of H_2O. Higher amts. may be used at the beginning of the treatment to accelerate the removal of old deposits. In recirculating cooling systems the concn. of bicarbonate may be limited by periodical purge of a portion of the H_2O. In addn. to the advantage of scale prevention and removal of existing deposition, the metaphosphate is an alk. reagent and will protect the engine from any corrosive influences which may enter the H_2O. E. C. Petrie

Progress in water treatment (Trautschold) **25**. Agricultural and cannery waste utilization (Wiegand) **12**. Waste problems in the pulp and paper industry (Skinner) **23**. Incineration, Carbonization and Reduction of Garbage, Rubbish and Sewage Sludge. A Bibliography. United States Works Progress Administration. New York: New York University. 146 pp. Limited free distribution. Reviewed in *Eng. News-Record* **123**, 430(1939).

Purifying water. Walter Wilson. Brit. 507,553, June 16, 1939. A reagent contg. *Ulmus fulva* (I) is used for flocculating coal-slurry water. A suitable reagent is obtained by mixing I, borax, glycerol and potato starch with boiling H_2O.

Apparatus for deaerating water. The Permutit Co. Ltd. Brit. 506,616, June 1, 1939.

Softening water. Egon Zentner. Brit. 507,750, June 16, 1939. This corresponds to Fr. 826,672 (*C. A.* **32**, 8053[2]).

Apparatus for filtering and base-exchange softening of water. Eric Pick (to Permutit Co.). U. S. 2,170,975, Aug. 29. Various structural and operative details.

Base-exchange materials. Ellis-Foster Co. Brit. 506,807, June 5, 1939. See Fr. 830,787 (*C. A.* **33**, 1428[1]).

Carbonaceous zeolites. Ray Riley (to Permutit Co.). U. S. 2,170,065, Aug. 22. Lignites or soft coals are prepd. for ion-exchange purposes such as use in treating water by impregnating a granular mass of the material with H_2SO_4 at least equal to the wt. of the treated material and dild. to below 70% strength and heating to concentrate the acid and produce chem. action on org. compds. in the material so that its ion-exchange properties are improved, and then washing residual acid from the material.

Compositions for preventing or removing corrosion in boilers. Robert H. Turnbull. Brit. 507,072, June 8, 1939. These comprise a colloidal mixt. of sucrose 10–18, glucose 9–15 and tannin 9–15 in H_2O 20–50%, with or without a small quantity of essential oil, e. g., clove oil, vegetable oil, e. g., castor oil, colloidal graphite, Al_2O_3, Fe oxide, colloidal clay and (or) talc. The solid addns. above comprise up to 5%. One or more of the following may be added to the original colloidal mixt., with or without the solid addns.: Na_2CO_3 2–25, Na phosphates up to 10, Na aluminate 0.25–5 and Na_2SO_3 1–2%.

Apparatus and method for dosing feed water supplied to a storage container with small quantities of liquid reagent, e. g., anticorroding compounds. Robert H. Turnbull. Brit. 505,779, May 16, 1939.

Purifying organically polluted water. Oliver M. Urbain and Wm. R. Stemen (to Charles H. Lewis). U. S. 2,171,203, Aug. 29. App. is described, and a process for the purification of a polluted liquid such as sewage which involves passing the liquid through a bed of scrap iron

simultaneously with SO_2 and diffused air, forming Fe sulfates *in situ*, and thereafter treating the resultant liquid with $Ca(OH)_2$ and passing it to a settling zone.

Treating laundry waste. Oliver M. Urbain and Wm. R. Stemen (to Charles H. Lewis). U. S. 2,171,197, Aug. 29. In purifying laundry waste for discharge or reuse, suspended solids are initially removed, hydrolysis of the soap soln. is effected, as by use of HCl, and the soln. is passed through a filter charged with ZnO to remove, by chem. reaction, the fatty acids freed by the hydrolysis, and the fatty acid-free soln. is then passed through a chlorinated coal filter to effect removal of remaining org. matter. U. S. 2,171,198 relates to the recovery of fatty acids from their solns., such as laundry waste waters, by use of a filter charged with ZnO from which the fatty acids are subsequently recovered, as by use of superheated steam.

Purifying laundry waste. Oliver M. Urbain and Wm. R. Stemen (to Charles H. Lewis). U. S. 2,171,199, Aug. 29. Suspended solids are sepd. from laundry waste, the soap soln. is hydrolyzed, as by use of HCl, and is passed through a filter charged with an oxide such as hydrous ferric oxide at or below its isoelec. point, to remove fatty acids freed by the hydrolysis, and the fatty acid-free soln. is then passed through a chlorinated coal filter to remove remaining org. matter. U. S. 2,171,200 relates to a process which involves removing fatty acids from solns. such as laundry waste waters which involves passing the soln. through a filter charged with an oxide such as hydrous ferric or stannic oxide at or below its isoelec. point and recovering the fatty acids by treatment of the filter material, as by use of steam. U. S. 2,171,201 relates to removing suspended solids from laundry waste, effecting hydrolysis of the soap soln., passing the soln. through a filter charged with TiO_2 to remove freed fatty acids, and further filtering the soln. to remove remaining org. matter. U. S. 2,171,202 relates to a like use of a filter contg. TiO_2 and recovery of the fatty acids from the filter material, as by use of steam.

Fumigation of rooms, etc., to kill insects and micro-organisms. Ivar Rennerfelt. U. S. 2,171,315, Aug. 29. A method of killing insects and microörganisms in a substantially closed space comprises introducing hot non-poisonous gases substantially composed of a mixt. of CO_2, H_2O and air, creating a blast of the gases, initially and continually directing the gas downwardly while the gas is at its highest temp., and causing circulation thereof until the entire space is substantially uniformly filled with the gas at lethal temp.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

Soil survey of Wales. Progress report, 1935–8. South Caernarvonshire. D. O. Hughes and Evan Roberts *Welsh J. Agr.* **15**, 272–301 (1939); cf. *C. A.* **30**, 1483.—The soil types are described and chem. and mech. analyses are given. Deficiencies of Ca and P are widespread. K. D. Jacob

Soil profiles developed on limestone of the Great Oolite in the southern part of the Cotswold Hills (Gloucestershire and Wiltshire). A. James Low. *J. Southeastern Agr. Coll., Wye, Kent* No. **44**, 210–20 (1939); cf. *C. A.* **32**, 9360⁸. **Soil profiles developed on the forest marble of the Great Oolite (Middle Jurassic) in Somerset, Wiltshire and Gloucestershire.** *Ibid.* 221–33. **Soil profiles developed on the chalk (Upper Cretaceous) in southwest Wiltshire (Wiltshire Downs).** *Ibid.* 234–45.—The characteristics of the soils are outlined and pH values and $CaCO_3$ contents are given. K. D. Jacob

Comparison of the borers of Hey, Janert and Mitscherlich for taking soil samples of definite volume. B. Grosse. *Bodenkunde u. Pflanzenernähr.* **13**, 320–40 (1939). Sand and sandy loam soils were sampled with the app. of Hey (I) (*Bodenkundl. Forsch.* **6**, 54 (1938)), Janert (II) (*C. A.* **22**, 1644) and the 2 forms (III 1 and III 2) proposed by Mitscherlich (*C. A.* **30**, 8463⁶), and the vol. wts. of the samples were compared with those of cylindrical samples taken from the profile exposed in a pit by the procedure of Nitzsch (IV), the reproducibility of which was proved. III 1 and III 2 furnished rather variable indications, III 1 always low in the upper horizons, nearly correct lower down. III 2 was better near the surface of sandy soils, but tended to high values with deeper sampling. II was unsatisfactory with dry sandy soils, better in loams. I was unsatisfactory in a calcareous loam but good in damp sand and loamy soils, and in general the results therewith agreed best with IV. C. J. Schollenberger

Soil reaction and lime status of apple orchard. Rokuro Kawasima. *J. Agr. Chem. Soc. Japan* **15**, 744–50 (1939). —The reaction and lime-satn. status in the soils of the apple orchards deviated to a great extent. The soils having pH 5.5–6.0 and 50% lime satn. were most suitable for the growth of the apple tree. Y. Kihara

Change of oxidation-reduction potentials of water-logged soils. V. The application of the green manures in different stages of growth. Kisaburo Sibuya, Hideaki Saeki and Kenhan Ryu. *J. Agr. Chem. Soc. Japan* **15**, 133–8, *Bull. Agr. Chem. Soc. Japan* **15**, 17–18 (1939) (in English); cf. *C. A.* **32**, 7629⁹.—When *Pisum sativum* L. or *Sesbania sesban* L. Merrill. was applied as green manure to the water-logged soils at 30°, the younger or more nitrogenous plants reduced the soil potentials, while the matured plants or materials with a large C:N ratio lowered the potentials to a less extent and slightly raised them at a later period. Y. Kihara

Determination of the base-exchange capacity of soil. Alberto Malquori. *Ricerca sci.* **10**, 562–3 (1939).— A modification of the method of Parker (*C. A.* **24**, 452) is recommended for simplicity and accuracy. A table is given with a comparison of 6 methods and 2 types of acid soils, and in addn. 3 of the methods applied to a clay-lime soil pH 7.6. W. F. Bruce

Determination of the exchangeable bases in soil by the steaming method. Christ. Basileiados. *Bodenkunde u. Pflanzenernähr.* **13**, 243–9 (1939); cf. *C. A.* **31**, 7575⁷.— An improved procedure stated to be more rapid, better adapted to work on numerous samples and for calcareous soils is described: Exchangeable Ca and Mg are displaced from a 10-g. sample, previously washed with 200–250 ml. 80% EtOH to remove salts, by adding 150 ml. 2 *N* NaCl and leading in steam for 5–10 min. The mixt. is cooled and washed into a 250-ml. flask with 2 *N* NaCl to vol. Ca is detd. in a 50-ml. aliquot of the filtered soln., and the amt. found corrected for dissolved $CaCO_3$ by deducting the equiv. alky. of a similar aliquot titrated to the methyl orange end point with 0.01 *N* HCl. Mg is detd. in the filtrate from the CaC_2O_4 by pptg. as the oxine compd. (8-hydroxyquinoline) which is dried at 100–105° and weighed. K and Na are detd. in a second ext. made by a similar procedure except that $BaCl_2$ is substituted for NaCl as the displacing salt, and 200 ml. of the ext. is used for the detns. Ba is first pptd. by adding $(NH_4)_2CO_3$ and NH_4OH and the filtrate evapd. and ignited. The residue of salts is taken up in exactly 15 ml. water; one half of this soln. is used for pptg. Na as $NaMg(UO_2)_3(OAc)_9.6H_2O$, which is dried at 110–120° and weighed, and in the other half of the soln. K is pptd. as $K_2NaCo(NO_2)_6$ and titrated by Kramer and Tisdall's method. All the procedures are described in detail. C. J. Schollenberger

Potentialities of minor elements in the soil of canning crops. J. L. Newman. *Canning Age* **20**, 437–40, 456, 460 (1939).—The role of B, Mn, Cu, Fe, Zn and S in crop nutrition is reviewed. No new data. C. R. Fellers

The arsenic content of vineyard soils and the uptake of arsenic from arsenifercus soils by vines. R. Herrmann and H. Kretzdorn. *Bodenkunde u. Pflanzenernähr.* **13**, 169–76 (1939).—For the detn. of As in soil, 5 g. was digested in a 500-ml. Kjeldahl flask of As-free glass with

5 ml. concd. H_2SO_4 and 10 ml. 30% H_2O_2 for about 15 min. The mixt. was then washed into a 200-ml. flask and made to vol. An aliquot of the clear soln. contg. 5γ or less of As, usually 20 ml., was transferred to a 100-ml. Kjeldahl flask for the As detn. by Lockemann's method (*Z. Untersuch. Lebensm.* **72**, 224(1936)), which is described in detail. Although most of the soils tested showed only 1–2 p. p. m. As, exceptionally as much as 64 p. p. m. was found; in no case did the juice and skins of the grapes show a determinable As content, although up to 2.3 p. p. m. As was found in leaves. C. J. Schollenberger

Alteration in physical properties of soil from sewage irrigation. W. Hensel., *Bodenkunde u. Pflanzenernähr.* **13**, 257–304(1939).—Comparisons of soil taken with a cylindrical cutter designed to secure samples with min. disturbance of soil structure from fields receiving Berlin sewage since 1870 (I) and similar adjacent soils never treated with sewage (II) indicated no very distinct effect upon particle size; the fraction less than 0.1 mm. was generally higher in I, but indications for material less than 0.01 mm. varied. Loss on ignition was about 60% higher with I. Fine-pore space was relatively increased in all cases; one soil was definitely injured thereby, but a lighter soil was improved and corresponding changes in permeability to air were noted. Sewage-irrigated soils are wetter in spring and fall and the distribution of moisture in them tends to be less even than in other fields. Samples from I were invariably more easily wetted, an improvement, and show 3–5 fold higher heat of wetting. Samples from II had a single grain structure and sewage treatment rather decreased the tendency to crumb formation. Conclusion: The phys. effects of sewage irrigation are generally unfavorable, but on a light soil this is likely to be concealed by the fertility supplied, so that yields are increased. Forty-eight references. C. J. Schollenberger

A procedure for the serial comparison of physical soil properties of cylindrical samples taken under natural conditions. Wilhelm Schoel. *Bodenkunde u. Pflanzenernähr.* **13**, 305–25(1939).—Certain abnormalities in the growth of crops are assocd. with differences in the phys. properties of soils, demonstrable in a comparative way even when no abs. values can easily be obtained. Rapid procedures for comparing soil profiles sampled by the method of Hey (*Bodenkundl. Forsch.* **6**, 54–64(1938)), for sp. gr., percentage of dispersable, max., min. and capillary H_2O capacity, evapn. loss, rise and permeability to water, etc., are described. Forty references. C. J. Schollenberger

The influence of microörganic activity upon the dynamic behavior of the easily soluble phosphorus, potassium and nitrogen compounds of the soil. D. Feher, M. Frank and G. A. Manninger, Jr. *Bodenkunde u. Pflanzenernähr.* **13**, 341–52(1939); cf. *C. A.* **31**, 8781⁸.—Expts. with 2 soils, incubated at 25° and 25–90% satn. of H_2O capacity for periods of up to 12 months, indicate a connection between available P_2O_5, K_2O and N as detd. by the *Aspergillus* and chem. methods and bacterial and mold nos. developed. At 50–75% satn., bacterial nos. are at max., but molds increase at lower and decrease at higher H_2O contents. Available P_2O_5 and K_2O are highest at medium, nitrate at low medium and ammonia at higher moisture values. Bacterial nos. were more closely related to available P_2O_5 than to K_2O with one soil; with the other the relation was about the same. The data show that with the same soil, indications for available fertility may vary widely with exptl. conditions as these affect biol. growth. Seventeen references. C. J. Schollenberger

Soil microörganisms in North China and Inner Mongolia. I. Distribution of Azotobacter. Kinsi Suminoe and Minbu Tanaka. *J. Sci. Soil Manure, Japan* **13**, 461–2 (1939).—Of 11 soils examd., 8 contained *A. chroöcoccum* and 3 *A. beijerinckii* as well as *A. chroöcoccum*. *A. chroococcum* has more than 3 varieties and *A. beijerinckii* 2 varieties. Y. Kamoshita

Effects of certain minerals on the growth of root-nodule bacteria. I. Kametaro Konisi, Tosihisa Tuge and Akio Kawamura. *J. Agr. Chem. Soc. Japan* **15**, 139–46 (1939).—The quantities of mineral constituents in the bacterial body were estd. by means of the spectrographic method. When the bacteria in the root nodule of soybeans and lupine were cultured on the medium contg. yeast ext. and mannitol, the contents of P and Mg were higher but the content of Na was lower than those in the other microorganisms. Phosphoric acid was usually effective in stimulating the growth of the bacteria, while a large amt. of Ca was unfavorable for the development of the bacteria of soybeans and lupine. The antagonism between Ca and P was recognized as affecting the growth of bacteria. II. *Ibid.* 213–24.—Most of the minor elements in the root nodule had no effect on the growth of nodule bacteria. However, a small amt. of Mn and Cr stimulated the alfalfa bacteria on nitrate medium and a small amt. of Li the lupine bacteria on yeast water media. They also had a good effect on the respiration of nodule bacteria. The aq. ext. of some plants accelerated the growth of some nodule bacteria. The ext. of *Brassica juncea* was more effective than yeast water for alfalfa. The effect of the N content of the ext. of plants was negligible. In *Brassica juncea* the ash in the ext. was also effective. The increase of Na and Ca in the media was desirable. In *Bull. Agr. Chem. Soc. Japan* **15**, 18, 87–8(1939) (in English). Y. Kihara

Boron determination in soils and plants using the quinalizarin reaction. K. C. Berger and E. Truog. *Ind. Eng. Chem., Anal. Ed.* **11**, 540–5(1939).—Available B in soils is detd. by refluxing a 20-g. sample for 5 min., cooling, filtering under suction and evapg. 20 cc. of the clear ext. to dryness with 5 drops of K_2CO_3 soln. or 2 cc. of a satd. $Ca(OH)_2$ soln. The residue is ignited gently and then triturated in 5 cc. of approx. 0.36 *N* H_2SO_4. A 1-cc. aliquot is placed in a comparison vial and 9 cc. of 98.5% H_2SO_4 is added. After cooling, 0.5 cc. of quinalizarin reagent is added to the soln. This is allowed to stand for at least 15 min. and the B is then detd. by comparing with a set of standards. In the detn. of total B, a Na_2CO_3 fusion is made and the resulting melt is dissolved in H_2O and H_2SO_4 added to make the final pH of the soln. 5.5 to 6.0. The bulk of the sulfate is thrown out of soln. by the addn. of alc. The filtered soln. is made alk., evapd. to dryness and the residue ignited. After dissolving in dil. acid, the quinalizarin test is applied. In the detn. of the total B of plants, the plant tissue is ignited to a gray ash which is taken up with dil. acid. The quinalizarin test is then applied to some of the clarified soln. By means of this color reaction it is possible with proper control of the acidity to detect 0.0001 mg. of B. J. R. Adams

The importance of adsorbed magnesium with respect to the observed salinity of the soil. P. M. Breshkovskiĭ *Uchenye Zapiski Kazan Gosudartst. Univ.* **97**, No. 1, 151–76(1937); *Chem. Zentr.* **1938**, I, 972.—Irrigation expts. were carried out to det. the effects of Ca, Mg and Na salts on the structure of the soil. In cases of complete satn. of the soil with a single cation the relative values for Mg and Na, resp., compared with Ca ion = 100, were: dispersion 132, 1358; rate of swelling 226, 5384; reduction in velocity of filtration 223, 6778. Satn. of the soil with more than 1 cation caused fluctuations in values which were dependent on the structure and compn. of the soil, the amt. of org. matter present and the manner in which satn. occurred. With respect to the effect of these cations on the hygroscopicity of the soil, the series Mg > Na > Ca corresponds with the values for the effective radii of these ions. With regard to their influence on the max. hygroscopicity detd. according to Mitscherlich, the series becomes Na > Mg > Ca and corresponds with the hydration values of these ions and their mobility on the surface of the adsorbent. John O. Hardesty

Experiments on the action of calcium and magnesium compounds upon soil and plant. S. Gericke and E. P. v. Polheim. *Bodenkunde u. Pflanzenernähr.* **13**, 232–42 (1939).—Pot expts. with an acid loam, pH_{H_2O} 5.7, pH_{KCl} 5.0, completely fertilized and with sulfates or carbonates of Ca and Mg in addn., indicated that with uncropped soil the sulfates had no significant effect upon pH. Cropped to barley the sulfates proved physiologically acid and tended to reduce the assimilation of P_2O_5 and the proportion of grain in the crop. In general, German soils are amply

supplied with sulfates, and a special fertilization to furnish them is seldom desirable. When Mg is deficient, $MgCO_3$ is a better source than $MgSO_4$. Fifteen references. C. J. Schollenberger

The effect of raw phosphate upon the growth of trees on acid forest soils. W. Jessen. *Bodenkunde u. Pflanzenernähr.* **13**, 249–56(1939).—Expts. with larch seedlings in Neubauer dishes filled with 2 sandy soils at about pH_{KCl} 4 (cf. *C. A.* **33**, 5573[7]) indicated that without liming raw Algerian phosphate was practically as effective as superphosphate or basic slag When limed to pH 5, superphosphate was the best source of P_2O_5 and the raw phosphate almost inactive, especially on the soil contg. most silt. Both soils decreased considerably in exchange acidity and increased slightly in pH during the expt.; except with basic slag this unexplained effect was practically the same with or without a P_2O_5 fertilizer. Seventeen references. C. J. Schollenberger

The relative fertility of certain tomato-producing soils for the canning industry. Jackson B. Hester and F. A. Shelton. *Am. Fertilizer* **90**, No. 10, 5–6, 24, 26(1939); cf. *C. A.* **33**, 1431[5].—Tabulated data are given which show the percentage distribution of the pH value, the org. matter content, and the easily sol. Ca, Mg, P and K, as extd. with dil. $NaC_2H_3O_2$ soln., in tomato-producing soils in 18 states. W. H. Ross

The avoidance of high losses in growing stocks of fir, pine and beech. K. Weinkauff. *Forstwiss. Centr.* **61**, 515–17(1939).—A short discussion of the importance of the phys. and chem. condition of the soil. C. K. H.

The germination of freshly harvested and of stored seeds of sea pea [Lathyrus maritimus Big.]. E. R. Dinnis and S. Jordan. *J. Southeastern Agr. Coll., Wye, Kent* No **44**, 140–2(1939); cf. *C. A.* **32**, 9373[8].—Treatment of fresh seed with concd. H_2SO_4 for not more than 15 min. induced max. germination with min. damage; longer treatments (0.5–1.0 hr.) caused a proportionate increase in damage to the seed. Recently harvested seed, when acid treated, had a slower rate of germination than did seed which had been acid treated after storage for some months. Seed that had been stored for 8 months and then treated with acid showed no deterioration in germination capacity during an addnl. 8-month storage period. K. D. Jacob

Green manuring experiments. IV. F. Perkner, E. Wiese and B. Nowrzella. *Bodenkunde u. Pflanzenernahr.* **13**, 370–84(1939); cf. *C. A.* **33**, 2271[5].—Under present economic conditions in Germany, growing any crop only to be plowed under for green manure is not to be encouraged. A nonbitter variety of lupine is now available, which is relished by stock and equal to the old varieties in all other respects; when fed and the manure returned to the soil, its net value is greater than if plowed under. Crimson clover is even more valuable, as it is a good hay crop and the roots remaining in the soil contribute about 4 times as much org. matter and N as do lupine roots and stubble. Potatoes do especially well after crimson clover. C. J. Schollenberger

Pot experiments for evaluating the phosphoric acid in ammoniated superphosphate and Nitrophoska. W. Lehmann. *Bodenkunde u. Pflanzenernähr.* **13**, 225–31(1939).—In limed pots of slightly acid loam and a similar neutral soil mixed with sand, the P_2O_5 of ammoniated superphosphate (Kalkammonphosphat) with 19.2% N and 19.8% P_2O_5 was about as well utilized by oats as that of ordinary superphosphate, basic slag and the concd. complete fertilizer Nitrophoska. C. J. Schollenberger

Determination of available phosphoric acid in fertilizers. G. S. Blyakher. *Zavodskaya Lab.* **8**, 409–13(1939); cf. *C. A.* **33**, 8888[2].—A review of the literature is followed by a description of B.'s expts. with $(NH_4)_2C_2O_4$ and H_2SO_4 to det. their use as substitutes for tartaric acid in the detn. of the available phosphates and fertilizers. Under certain conditions, $(NH_4)_2C_2O_4$ and 0.1 *N* H_2SO_4 may be used as solvents for available phosphate in apatite concentrates and superphosphates. H_2SO_4 is preferred because it is less expensive and it is advantageous for the rapid detn. of the phosphate. Thirteen references. B. Z. Kamich

Studies on the fertilizing value of Mayon Volcano ash. I. Effects upon plants of liberal applications of the volcanic ash. Rafael B. Espino. *Philippine Agr.* **28**, 133–42(1939).—Mayon Volcano ash applied to Lipa clay loam (cf. *C. A.* **33**, 7020[2,4]) in relatively large amts. (0.8, 1.6, 3.2, 4.8 and 15.6 kg. of ash per 14 kg. of soil) was harmful to young corn, radish and rice plants. It is suggested that the harmful effects were due (1) to changes in the phys. character of the soil brought about by the very fine particles of the ash and the large amts. of Al, Na and K that it contained, (2) to physiol. unbalance of the soil soln., (3) to rendering the soil P insol. by reaction with the Al_2O_3, Fe_2O_3 and CaO of the ash and (4) to Al toxicity. The first 2 effects are the most probable causes. Colin W. Whittaker

A trial of organic fertilizers. N. L. Tinley and D. M. Bryant. *J. Southeastern Agr. Coll., Wye, Kent* No. **44**, 134–9(1939).—In a 3-yr. expt. on successive crops of mangels, potatoes and wheat shoddy, hoof and horn meal, castor meal and dried poultry manure gave results inferior to farmyard manure when applied on an equiv. N basis, but when these materials were supplemented with inorg. fertilizers to contain equiv. P and K the results were similar to those obtained with farmyard manure. All the fertilizers, as well as the farmyard manure (8 tons/acre), were applied only in the 1st yr. of the expt. A complete mixt. of inorg. fertilizers, adjusted to provide equiv. N, P and K to the org. materials, but applied in 3 dressings each equiv. to $^1/_3$ of the org. fertilizer dressings, gave the highest yields in the 2nd and 3rd yrs. of the expt. although it proved inadequate for the mangel crop in the 1st yr. K. D. Jacob

Control of the cochylis moth by the use of chemicals during the winter. O. Tanke and Roesler. *Nachrbl. deut. Pflanzenschutzdienst* **19**, No. 7, 58–61(1939).—Inconclusive results in the effectiveness were obtained on the addn. of nicotine, derris and pyrethrum to emulsions of coal-tar distillates and mineral oil as dormant sprays against the cochylis moth. V. L. Frampton

The control of leaf-cutting ants. K. Escherich. *Z. angew. Entomol.* **25**, 528–30(1938–9).—Review. C. H. R.

The control of hop red spider: some recent experiences. S. G. Jary. *J. Southeastern Agr. Coll., Wye, Kent* No. **44**, 37–8(1939).—The spider is effectively controlled by spraying the hop plants with 1–100 lime-S. With heavy infestations, 2 applications at intervals of 8–10 days are desirable. The spray must not be applied after the cones begin to form or they will be completely browned, otherwise the risk of damage is negligible. No appreciable injury results from the interaction of lime-S and Bordeaux mixt. when applied within a few days of each other. Application of a 5% tar-oil wash to the large cracks in hop poles gave effective *control of mites* hibernating therein. K. D. Jacob

Control of mites by means of adherent substances. P. Steiner *Z. angew. Entomol.* **26**, 180–3(1939).—A spray of 0.5% gelatin and 0.25% of a com. wetting agent gave excellent control of *Tetranychus telarius*. C. H. Richardson

The control of strawberry aphis [Capitophorus fragariae Theo.] and tarsonemid mite [Tarsonemus pallidus Banks]. R. M. Greenslade and A. M. Massee. *Ann. Rept., East Malling Research Sta., East Malling, Kent* **26**, 186–90(1938)(Pub. 1939).—In expts. with a no. of insecticidal materials, the best control of *C. fragariae* was obtained with a spray containing nicotine 8 oz. and soft soap 8 lb./100 gal. In lab. expts. complete kills of *T. pallidus*, without injury to the strawberry plants, were obtained only by dipping the leaves for 5 sec. in solns. of either lime-S 3% plus Lethalate 0.05%, NH_4 polysulfide 3% plus soap 1%, pyridine or nicotine 0.1% plus Lethalate 0.05% or lauryl thiocyanate 1% plus soap 1%. The sprays did not give satisfactory control of the insect under field conditions. K. D. Jacob

A new system of anthelmintic control for gastrointestinal parasites of ruminants. Donald W. Baker. *Cornell Vet.* **29**, 192–7(1939).—Excellent control of small tri-

chostrongyles in calves, sheep and goats was obtained by spraying 2–3 cc. of a 5% $CuSO_4$ soln. into the throat and immediately drenching the animal with a mixt. of equal parts of tetrachloroethylene and mineral oil at the rate of 0.2 cc. per lb. live wt. K. D. Jacob

Further trial of the preparation Naaki for grain weevil control in 1938. Arnold Claus. *Z. angew. Entomol.* **26**, 165–70(1939).—Results of tests with a proprietary insecticide are given. C. H. Richardson

Injury to broad leaf and coniferous trees by Novosil and related dusting materials, and their action on nun moth and Nematus larvae. Hellmuth Gabler. *Z. angew. Entomol.* **25**, 609–27(1938–9).—Results of expts. with a no. of new proprietary dusts contg. cresol derivs. are described. All but 2 of these dusts burned the foliage of the plants tested and all of them appeared to be about equally effective against larvae of the insects tested. C. H. R.

Skin spot (Oospora pustilans Owan and Wakef.) of the potato, and its control by tuber disinfection. T. N. Greeves and A. E. Muskett. *Ann. Applied Biol.* **26**, 481–96(1939). Instantaneous dipping with a com. organo-Hg compd. was the most satisfactory control measure, but steeping 90 min. in 0.1% $HgCl_2$ soln. gave promising results. HCHO was inefficient. A com. dust fungicide was ineffective under exptl. conditions. C. H. Richardson

Apple canker. II. Experiments on the incidence and control of shoot infections. R. W. Marsh. *Ann. Applied Biol.* **26**, 458–69(1939).—Apple shoots sprayed with a Bordeaux-casein-petroleum oil mixt. showed a much lower percentage infection by *Nectria galligena* than unsprayed shoots. As a wound-treating material to protect against entrance of *Nectria* spores, a mixt. of $CuSO_4$.-H_2O, $Ca(OH)_2$ and linseed oil was most promising. C. H. Richardson

Internal black spot of canning beets and its control. J. C. Walker, James P. Jolivette and John G. McLean. *Canning Age* **19**, 489–91, 508(1938).—This defect is caused by a lack of B in the soil and can be corrected by adding 20–60 lb. of borax per acre. The addn. of borax directly in the seed row may injure germination and the young seedlings. C. R. Fellers

Recent investigations on the cause of reclamation disease and the action of copper as a trace element. W. Hoffmann. *Bodenkunde u. Pflanzenernahr.* **13**, 139–55(1939); cf. Arnd and H., *C. A.* **32**, 3881⁹.—From expts. with oats grown in solns., purified glass sand with added humus and HCl- and heat-treated sandy heath soil on which crops are affected by reclamation disease, it is concluded that lack of available Cu is the cause of the characteristic symptoms. Sufficient Cu was absorbed from a soln. painted upon the leaves of the young plants to produce a normal crop without any treatment of the soil. Some soils show insufficient available Cu for a healthy crop under certain conditions, but after being dried out or moderately heated (110–130°) the soil Cu becomes more available; the drying also causes a decrease in pH of the soil in many cases. Cu is not to be considered merely as a plant stimulant or remedy for abnormal conditions, but as an essential plant nutrient although only a trace is required and an excess is very toxic. Fourteen references. C. J. Schollenberger

Experiments on combating the heather moor disease with copper slag. W. Nicolaisen, W. Seelbach and B. Leitzke. *Bodenkunde u. Pflanzenernahr.* **13**, 156–69(1939).—Pot and field expts. with oats on a humus sandy heath soil, pH_{H_2O} 4.2, on which the crop is affected by the so-called heather moor disease (cf. preceding abstr.), indicated that 91 lb. $CuSO_4.5H_2O$/acre applied to the soil is an effective remedy, but 273–819 lb. of a copper refinery slag, essentially $FeSiO_3$ with small percentages of CaO, MgO, Al_2O_3, MnO, ZnO, PbO, CuO (0.5%), S and traces of Ni and Co, is equal in effect. The slag is now a waste product which has found no use except as ballast, but the first-year expts. indicate that when ground to meal it is capable of increasing the productivity of large areas of Cu-deficient soils in northern Germany. C. J. S.

Responses of the blowflies, Cochliomyia americana C. and P. and Phormia regina Meigen, to stimulations of the tarsal chemoreceptors. C. C. Deonier. *Ann. Entomol. Soc. Am.* **32**, 526–32(1939).—Gustatory chemoreceptors are present on the tarsi and proboscis of *Cochliomyia* by which nonvolatile substances such as sugars and salts can be detected. $HgCl_2$ was more repellent to *Cochliomyia* in 0.5 *M* sucrose soln. than in 1.0 *M* sucrose; this compd. was less repellent to *Phormia* which were 48 hrs. old than those 24 hrs. old. The presence of $HgCl_2$ in concns. as low as 0.25% caused a slight lowering of the feeding response. No marked differences in response of the sexes were observed. With sucrose soln. contg. 2% $HgCl_2$ as the only source of food and water, the flies died of starvation. C. H. Richardson

Applied microbiological investigation in cane-sugar manufacture. XV. Rhizosphere of cane. Masasi Adati. *J. Soc. Trop. Agr., Taihoku Imp. Univ.* **10**, 441–5(1938).—When the cane was cultivated on sand with $(NH_4)_2SO_4$, more nitrate than NH_4 salt was found in the roots and the surrounding soil. There was also a large amt. of nitrification bacteria. Y. Kihara

Insect pests of brassica seed crops in Romney Marsh. S. G. Jary and M. D. Austin. *J. Southeastern Agr. Coll., Wye, Kent* No. 44, 73–83(1939).—Pb arsenate (6.4% As_2O_5), derris (0.55% rotenone), pyrethrum (1% of pyrethrum ext. in equal parts of colloidal clay and ground North African phosphate rock) or colloidal SiO_2 dust do not give consistently satisfactory control of *Meligethes aeneus* F. on kale and swede plants under either field or insectary conditions. Ground North African phosphate rock alone had little effect on the beetles. K. D. J.

A note on the germination of St. John's wort seed. A. B. Cashmore. *J. Council Sci. Ind. Research* **12**, 181–2(1939).—St. John's wort seed requires an after-ripening period of some 4–5 months before becoming fully viable. Dipping seed-carrying sheep in standard arsenical dips has no effect on the viability of the seed carried. There is no indication that spraying ripe seed heads with As or chlorate sprays in the field will have any adverse effect on the viability of the seed contained in them. J. R. Adams

Penetration of hydrocyanic acid into packing material for nursery plants. Hermann Fischer. *Nachrbl. deut. Pflanzenschutzdienst* **19**, No. 3, 19–20(1939).—The mortality of the second instar of *Eulecanium pulchrum* King, March, was greater if the insects were exposed directly to HCN gas at a concn. of 10 g./cu. m., at 13° than if they were protected by straw bundles. *Ibid.* No. 4, 32–3.—HCN only slowly penetrated bundles of vegetable materials that were fumigated for insects. V. L. Frampton

The action of coal-tar distillate emulsions with particular regard to the temperature of application. Ferdinand Beran. *Nachrbl. deut. Pflanzenschutzdienst* **19**, No. 4, 1–7(1939).—The effectiveness of dormant sprays made up of emulsions of coal-tar distillates against meal worms and San José scale increases with the b. p. of the distillate and the temp. at which the spray is applied. Vernon L. Frampton

Spray-residue investigations. III. The influence of petroleum oil and of lime-sulfur on the retention of lead arsenate on apples. H. Shaw and W. Steer. *Ann. Repl., East Malling Research Sta., East Malling, Kent* **26**, 199–203(1938)(Pub. 1939); cf. *C. A.* **32**, 7124⁷.—Oil appeared to increase the arsenical residue except where it was used with lime-S sprays. Lime-S by itself had no effect. Fruit growth was checked wherever lime-S, with or without oil, was used. The apparent loss of residue, in terms of As_2O_3 per kg. of fruit, was accounted for by attenuation due to fruit growth and there was no evidence of actual loss by weathering. K. D. Jacob

Use of sulfur in agriculture. III. Effect of sulfur on the physical properties of soil. R. Cultrera and A. Curini-Galletti. *Ann. chim. applicata* **29**, 198–205(1939); cf. **32**, 9368⁹.—Addn. of S to soils rich in org. substances does not give any advantages as the acidity causes coagulation of colloidal matter and otherwise counteracts the effects of the humic substances. Coagulation of the

colloids also affects the permeability and capillarity of the soils. A. W. Contieri

The influence of insecticides and fungicides on bees. III. The action of pyrethrum on the honey bee. Friedrich K. Böttcher. *Z. angew. Entomol.* **25**, 419–41 (1938–9); cf. *C. A.* **33**, 2429.—Pyrethrum is a strong stomach poison for *Apis mellifera;* its action is considerably influenced by temp. At 20°, the min. lethal dose of total pyrethins is 0.03 0.27 γ; at 34.5° it is 0.27 3.3 γ. The corresponding values for other compds. are: As as As_2O_3 0.25 γ; $CuSO_4.5H_2O$ 10 γ; $FeSO_4.7H_2O$ 51 γ nicotine about 60 γ. Pyrethrum is also a contact poison for bees; and its action likewise varies with the temp. Pyrethrum sprays and dusts at total pyrethrin concns. up to 0.009% are not dangerous to honey bees. IV. **The action of derris on the honey bee.** *Ibid.* 681–702.—Derris has a stomach poison and contact action, but not a fumigating action on the honey bee. In both actions there is little effect of temp. As a stomach poison, rotenone gave a min. lethal dose of 0.5 γ to more than 11 γ; the median lethal dose is about 3 γ rotenone. As a contact poison, derris gave variable results; but suspensions contg. 0.02 to 0.1% rotenone killed 25 to 33% of the bees tested. The use of derris dusts contg. 1.75% rotenone and derris sprays contg. 0.04% rotenone do not endanger honey bees. C. H. Richardson

A new contact insecticide for forest pests. Christoph Hofmann. *Z. angew. Entomol.* **25**, 38; 97 (1938 9).—Two proprietary materials, nos. 2152 and 2172 of the I. G. Farbenind. A.-G., were tested on various insects in comparison with dinitro-*o*-cresol. Their insecticidal efficiencies were greater and they were less injurious to plants. C. H. Richardson

Modern methods of seed disinfection. W. A. R. Dillon Weston. *Ann. Applied Biol* **26**, 636–40 (1939).—Review C. H. Richardson

Borax [use on B deficient soils] (Kitchen) **18**. Genesis of montmorillonite and kaolinite and conditions of their joint occurrence in the colloids of soils and clays (Sedletskii) **8**.

Schmitt, Ludwig: Arbeiten des Reichsnährstandes Bd. XXI. Die Kalkdüngung. Berlin: Reichsnährstand Verlags-G. m. b. H. 96 pp. M. 1.65.

Compositions for accelerating plant growth. The Dow Chemical Co. Brit. 506,910, June 1, 1939. These consist of an auxin and a colloidal earth, e. g., bentonite, fuller's earth, auxin and a paraffin emulsion or an emulsion of a wax mixed with a colloidal earth. The mixt. may also include an NH_4 salt of an unsatd. fatty acid having 2 or more double bonds.

Insecticidal sprays containing light mineral oils. Wm. B. Parker (to Calif. Spray-Chemical Corp.). U. S. 2,171,598, Sept. 5. For decreasing the tendency for a light oil spray to be absorbed by plant leaves, there is added to the oil about 1–5% of an oil-sol. Al soap such as Al stearate or the like. Cf. *C. A.* **33**, 3059.

Insecticidal and fungicidal sulfur compounds of glycerides. Frederick E. Dearborn (to the Public for free use). U. S. 2,169,793, Aug. 15. S is introduced into the double bonds of a glyceride of a long-chain unsatd. fatty acid such as triolein or trilinolein by heating the glyceride with S at 135–220° in the presence of I as a catalyst.

Coating particles such as those of insecticides and fungicides with an adhesive such as an oil mixture. Alexander G. Galloway (to the people of the U. S. A. for free use). U. S. 2,172,001, Sept. 5. Particles to be coated while entrained in an air stream are brought into contact with an intersecting air stream carrying the adhesive in finely divided form. App. is described.

Parasiticides suitable for use on plants, etc. James F. Adams and Alexander A. Nikitin (to trustees for the Crop Protection Institute). U. S. 2,172,314, Sept. 5. A Cu fungicidal compd. such as $CuSO_4$ is used with Na zeolite or other alkali or alk. earth metal zeolite, which prevents caking of dusting compns. or creaming or breaking of oleaginous compns. contg. the specified ingredients together with an oil.

16 THE FERMENTATION INDUSTRIES

Production of alcohol from potatoes by the amyloprocess. II. Sinzi Doi. *J. Agr. Chem. Soc. Japan* **15**, 661–8 (1939); cf. *C. A.* **33**, 9531.—The saccharification of dried potato by *Rhizopus javanicus* was most suitable when the potato was heated with city water contg. HCl under pressure of 40 lb. for 60 min. *Rhizopus javanicus* was most preferable for the saccharification. It was recommended that the yeast should be added 2 days after the inoculation of *Rhizopus*. When 3% of rice bran was added to the dried potato, the alc. fermentation was more favorable. Y. Kihara

Production of alcohol by dextrin-fermentable yeast Sinzi Doi. *J. Agr. Chem. Soc. Japan* **15**, 639–44 (1939).—The hydrolysis of the dried potato into achrodextrin was most preferable when it was boiled with 6 times of 0.43% HCl under pressure of 50 lb. for 30 min. The yield of dextrin was 37.5%. The dextrin soln. was neutralized with $CaCO_3$ and was fermented by *Schizosaccharomyces pombe* var. iotocusis II nov. var., *Saccharomyces logos* or *Schizosaccharomyces pombe*. The fermentation ratio was 77.0–80.2%. The fermentation by *Saccharomyces logos* was most suitable. Y. Kihara

Waste problems in the fermentation industry. C. S. Boruff. *Ind. Eng. Chem.* **31**, 1335–7 (1939).—Brewery wastes are disposed of by digestion and secondary aerobic stabilization; yeast wastes by digestion and trickling filters; still wastes from alc. fermentation of molasses by evapn. and incineration; still slop from acetone-butanol fermentation of molasses by anaerobic digestion followed by aerobic stabilization; distillers' slop from bourbon mashes by screening, centrifuging and multiple-effect evapn. at a profit; rye slops similarly with difficulty. Various minor amts. of solids recovered are sold for contents of vitamins. Foster Dee Snell

Decomposition and gas production of cornstalks under anaerobic conditions at 28° to 30°. G. H. Nelson, Robert P. Straka and Max Levine. *Iowa State Coll. J. Sci.* **13**, 161–80 (1939).—Chopped cornstalks and cornstalk flour were: (1) subjected to an active methane-producing seed and (2) sealed in tap water without inoculation. Sometimes daily but usually at the end of 3, of 5, of 10, of 20 and of 30 days analyses were made for: total solids, vol tile solids pentosans, cellulose and lignin. The data are reported in 11 tables and 7 series of graphs. The flour fermented 43% more rapidly (gas production). The gas was 34 5% CO_2 and 55–9% methane. At the 3-, 20- and 30-day periods for the flour, loss of cellulose and pentosans accounted for 95% of the gas: for the chopped stalks only 75%. For the 5- and 10-day periods more cellulose and pentosans were decompd. than could be accounted for by the gas produced. The loss of cellulose and pentosan was greater in the flour and the loss of lignin greater in the chopped stalks. Incubation of corn stalks gives little promise of usefulness in pulp prepn. but fermentation with an active seed does give some promise. F. E. Brown

Improved methods and equipment in the wine industry. V. deF. Henriques and M. W. Turbovsky *Canning Age* **16**, 181–4 (1937).—The modern Calif. wine industry is described. C. R. Fellers

Determination of germinating capacity of brewing barley by means of sodium acid selenite. H. Kipphan.

Allgem. Brauer- u. Hopfen-Ztg. **78**, 995(1938).—The regular (Aubry), dinitrobenzene (Enders, *C. A.* **33**, 9535[4]) and selenite (Eidmann, *C. A.* **32**, 5029[9]) methods for detn. of germinating capacity of barley are compared. Preference is given to the selenite procedure which was found to give results that are in good agreement with the regular method. A modification of the selenite procedure is described. S. Laufer

Varietal differences in barleys and malts. VII. Starch-liquefying activity, autolytic diastatic activity and their correlations with saccharifying and proteolytic activity. Henry R. Sallans and J. Ansel Anderson *Can. J. Research* **17**, C, 361-72(1939); cf. *C. A.* **33**, 8909[1].—Detns. made on 144 samples of malt, representing 12 varieties grown at 12 exptl. stations in Canada, show that varietal differences exist with respect to starch-liquefying activity (max. 768, min. 275 units) and autolytic diastatic activity (max. 958, min. 664 units). Varieties of poor malting quality tend to be low with respect to both properties. The effect of environment is also considerable (liquefying, max. 510, min. 288; autolytic, max. 806, min. 704). The correlation coeffs. (r) among liquefying, autolytic diastatic, saccharifying, and proteolytic activities of malt and total barley-saccharifying activity were studied. Significant intervarietal assocns. exist between each pair of properties, but partial correlation studies suggest that only those between saccharifying activities of barley and malt (r = 0.90), and between liquefying and autolytic activities of malt (r = 0.97) represent real and close relations. The other assocns. between pairs of enzymic activities seem to reflect mainly pos. correlations between each activity and total salt-sol. N in the barleys. Significant intravarietal assocns. also exist between each pair of enzymic activities, and between each activity and total barley N. It appears that environmental factors which tend to increase total N also tend to increase each enzymic activity, but these do not increase regularly with respect to each other and are not closely related. Partial correlations independent of total N suggest that only barley and malt-saccharifying activities (r = 0.67) and liquefying and autolytic activities of malt (r = 0.63) are related within varieties. The rate of autolysis in samples of different varieties from the same station appear to be controlled almost entirely by starch-liquefying activity, but the latter property is not the limiting factor controlling autolysis in samples of the same variety from different stations. Within varieties some other factor, presumably starch resistance, must play an important part. J. W. Shipley

Composition of 1939 malts from viewpoint of brewhouse procedure. Stephen Laufer and Robert Schwarz. *Am. Brewer* **72**, No. 6, 39-45, 52, 56, 62(1939).—A no. of 1939 malt samples received from 3 leading malthouses were subjected to regular analysis including diastatic and proteolytic power. In addn., the sol., permanently sol. and formol N were detd. on the cold-water exts. and lab. worts. On the basis of these analyses and also on that of exptl. brews which were made it was concluded that the 1939 malts are not entirely satisfactory with regard to protein modification. A proper protein rest procedure is recommended. S. Laufer

Determination of germinative, diastatic and proteolytic powers as factors for evaluation of malt. L. Heintz. *Schweiz.-Brau. Rundschau* **50**, 95-109(1939).—Opinions as to allowable limits for germinative power of malt differ widely (6–30%). Expts. conducted with malt samples of high (37.4%) and low (5.6%) germinative power indicated that a kilning temp. of 80° yields no germination, whereas temps. not exceeding 50° give malts with high germinating power. Diastatic power is reduced by temps. of 60–70°, while proteolysis as measured by formol titration needs a temp. of 80° for reduction. Values found for proteolysis showed no relationship to malt modification. S. Laufer

Froedtert experimental malting unit. T. L. Haberkorn. *Am. Brewer* **72**, No. 5, 32, 60(1939).—The unit was designed for the study of malting conditions and methods. It consists of 6 cabinets in which the barley samples are steeped, germinated and kilned. Conditioned air of [illegible] automatically corded. S. Laufer

Extraction of malt husk. L. Heintz. *Schweiz.-Brau. Rundschau* **49**, 111-13(1938).—Extn. of ground malt husks with alc. yielded 9.063%. The ext. was similar in properties to that obtained from hops and barley husks. Tannins were absent. S. Laufer

Errors in hop analysis. C. Enders, G. Nowak and F. Becker. *Z. ges. Brauw.* **61**, 21-2(1938).—Heating of the mill in the course of grinding of the hop sample caused changes in the nature of hop constituents. It is recommended that the 50 g. of hops required for analysis be ground in two 25-g. portions and mixed subsequently, at least 3 min. being allowed for the mill to cool between grindings. For testing excess of Pb acetate employed for pptn. of humulone a soln. of dithizone is suggested in place of K_2S. The great errors resulting from the use of an insufficient amt. of Pb acetate are pointed out. In distn. of volatile solvents rubber stoppers may also be the source of error; all-glass app. is recommended. S. Laufer

Which of the hop constituents is responsible for wort turbidity? L. Heintz. *Schweiz.-Brau. Rundschau* **49**, 47-55(1938).—In line with his earlier work on the constituents of barley husk (*C. A.* **28**, 3831[9]) H. carried out similar investigations on hops. A substance sol. in alc. was obtained, which is claimed to be responsible for the turbidity of wort. The substance is free from tannin. When dried for 4 hrs. at 105° it was found to contain 3.25% N and 4.03% mineral matter. S. Laufer

Cooling turbidity and cold turbidity [of wort]. L. Heintz. *Schweiz.-Brau. Rundschau* **49**, 61-4(1938).—The "cooling turbidity" represents the fine ppt. sepg. at about 55°, while the "cold turbidity" is formed at relatively low temps. Investigations carried out on the ppt. produced in the cold showed it to be free from tannin and to contain Fe, SiO_2 and protein matter. S. Laufer

Production of turbid worts under practical brewery conditions. G. W. A. Brischke. *Z. ges. Brauw.* **61**, 37-40(1938).—The effect of the various wort turbidities (hot, cold, coarse and fine) on yield and quality of the resulting beer is discussed. S. Laufer

Practical research in the brewery. Utilization of by-products. Geo. B. Sippel. *Am. Brewer* **72**, No. 7, 33-6(1939).—A brief discussion is presented of some of the problems confronting the brewing industry. Among the topics touched upon are: prepn. of adjuncts from corn and rice with a readily convertible starch, evaluation of American hops, the question of continuous processing, oxidation, pasteurization, shipping problems and utilization of by-products. S. Laufer

Alterations in the steam and power equipment of a brewery. Fritz Schiffner. *Arch. Warmewirt.* **20**, 131-4(1939).—The power and steam cycle is rather fully described. The alteration was mainly in the use of higher steam pressures. Ernest W. Thiele

New method for sterilization of (brewery) water. M. Hamburg. *Brau- u. Malzind.* **38**, 87-9(1938).—Brewery water was effectively sterilized by passing the water over a material contg. a compd. of the formula $2Ag.MnO_2$ (active O enhancing the oligodynamic action of Ag). Brewery organisms, such as mold spores, yeasts and bacteria, were added to water in large quantities. After passage through this material the water showed practically no growth when plated. A heavily infected filter pulp was rendered sterile when kept for 30 min. in water treated in such manner. It is not recommended to use this method for washing yeast. S. Laufer

Effect of mineral constituents of water [on beer]. M. W. Brenner and S. Laufer. *Am. Brewer* **72**, No. 5, 21-2, 71(1939).—A discussion of the most important mineral constituents of brewing water and their effect on properties of the resulting beer. The importance of correcting not only the mash-in water, but also the sparge water, is stressed. S. Laufer

Microchemical methods for the examination of beer.

Fh. Ghimicescu. *Mikrochemie* **27**, 197–210(1939).—A comprehensive review of recent microchem. work. W. T. H.

Foam stability of beer. Robert Schwarz and Stephen Laufer. *Am. Brewer* **70**, No. 12, 30–4(1937).—Factors affecting foam stability of beers are discussed; good barley quality, slow germination at low temps., restricted protein rest, use of fresh hops of good quality, short kettle boiling, cautious chillproofing and filtration, and proper carbonation influence favorably the head of foam on beer. The methods of Helm (*C. A.* **28**, 3175[3]; **30**, 3582[8]) and of Blom (*C. A.* **29**, 882[2]; **30**, 5720[7], 6505[3]; **31**, 5506[8]) wer modified (see following abstr.); the former was applied for detg. the foam stability of carbonated bottled and canned beer, while the latter served for measuring the foam capacity of uncarbonated beer at any stage of the brewing process. Expts. indicated that prolonged protein rest, sharp filtration, improper chillproofing and improper chillproofing materials, and low foam capacity affect the head of foam. Of various materials tested dextrin increased but slightly the foam capacity, gum arabic had a better and albumin the best effect, while peptones gave no improvement. S. Laufer

Determination of foam stability and capacity of beer. Stephen Laufer and Henry Ziliotto. *Am. Brewer* **72**, No. 8, 25–6; No. 9, 33–5(1939). Modifications of the methods by Helm and Blom are described (see preceding abstr.). For detg. foam stability, the attemperated beer is poured through a funnel into a jacketed foam cylinder (20°), and after 2 and 10 minutes the liquefied beer is withdrawn and weighed. The foam remaining in the cylinder is also ascertained by weighing. Wt. of foam after 2 minutes, in per cent of beer wt., represents foam formation, and wt. of foam after 10 minutes in per cent of beer wt., indicates foam retention. For measuring foam capacity 200 cc. of the decarbonated beer is placed in the jacketed cylinder (20°). The beer is converted into foam by means of CO_2 passing under definite pressure through a standardized filter candle. About 100 cc. of beer is withdrawn leaving only foam in the cylinder. After 5 and 10 minutes the liquefied beer is withdrawn and weighed; the remaining foam is also ascertained by weighing. The ratio of foam wt. after 5 and 10 min., resp., to the wt. of beer used is a measure of the foam capacity of beer. S. Laufer

Preliminary expts. on the use of root-initiating substances in hop propagation (Bailey) **11D**.

Recovering volatile substances from fermentation waste gases. Max Seidel. Brit. 505,940, May 19, 1939. In the culture of yeast and other microörganisms with the employment of aeration, the fermentation gases are washed in a scrubber or column app. to recover escaping products, e. g., EtOH, AcOH, by means of unfermented mash or wort in countercurrent flow to the gases, the enriched mash or wort being later used in yeast or microörganism culture or for fermentation purposes. Cf. *C. A.* **33**, 2649[2].

17—PHARMACEUTICALS, COSMETICS AND PERFUMES

W. O. EMERY

The search for more effective morphine-like alkaloids. Nathan B. Eddy. *Am. J. Med. Sci.* **197**, 464–79(1939).—New morphine-like alkaloids are discussed in this search for a nonaddicting analgesic. No methods of synthesis or chem. characteristics are given. Ruth E. Black

Revision of miscellaneous monographs of National Formulary VI. Anon. *Bull. Natl. Formulary Comm.* **7**, 352–415(1939). One hundred and sixty-five items are covered, of which 5 are deletions, 25 addns. and 137 have been revised. H. M. Burlage

Cosmetic manual. Cold creams. Joseph Kalish. *Drug Cosmetic Ind.* **45**, 430–2, 435(1939); cf. *C. A.* **33**, 8911[6].—These products consist mainly of an oil, H_2O, bees wax and preferably an alkali yielding a water-in-oil emulsion. The following groups of formulas are offered: water-in-oil emulsions without borax (29 formulas), and creams with borax which are superior (80). H. M. B.

Determination of nicotine in cigarets by denicotinization and by neutralization of nicotine. Nikos G. Manthos. *Chim. Chronika* (Greece) **4**, 163–7(1939)(in Greek).—Résumé of work published embracing the amts. of nicotine involved in the smoking of a cigaret (certain European makes), methods of analysis and procedures followed by several European countries. Lucien Y. Dyrenforth

Oxalate formation in ascorbic acid solutions. A. E. Jurist and W. G. Christiansen. *Am. J. Pharm.* **111**, 347–50(1939).—The data presented show that oxalic acid is present in the solns. in amts. from 0.19 to 11.14 mg. per cc. These quantities do not appear to be related to the concn. of the solns. because solns. of almost identical ascorbic acid concns., e. g., of monoethanolamine ascorbate, show widely varying amts. of oxalic acid Further, the nature of the base used, inorg. or org., seems to have little bearing on the formation of oxalic acid, as it was found that all solns. examd. contained oxalates. Finally, since all solns. examd. were stored in sealed, well-filled glass ampoules there is little likelihood that the oxidation of ascorbic acid to oxalic acid could be due to the effect of air but is, in all probability, due to an autoxidation such as referred to by Ghosh (*C. A.* **32**, 5042[9]) and others. It is significant that the amt. of oxalic acid formed appears to be disproportionate to the amt. of ascorbic acid lost by the solns on aging. The exptl. data on which these conclusions are based and the method by which oxalic acid can be demonstrated in solns. of ascorbic acid and its salts are presented. W. G. Gaessler

The biological assay of Philippine fish-liver oils for vitamin A. I. The vitamin A potency of "sanga" (Mobula eregoodoo-tenke) liver oil. M. Gutiérrez. *Acta Med. Philippina* **1**, No. 1, 1–10(1939); *Rev. filipina med. farm.* **30**, 346.—The oil contained 2400 U. S. P. units of vitamin A per g., detd. by the rat-growth method. L. E. Gilson

A new rapid electrical method of extraction of alkaloidal substances. J. F. Leyva. *Acta Med. Philippina* **1**, No. 1, 13–18(1939), *Rev. filipina med. farm.* **30**, 346.—The principle involved in the new method of extn. and the expts. undertaken are described. The automatic electron gage with the extn. cell and accessory app. are illustrated and explained. L. E. Gilson

Carbon monoxide in tobacco smoke. J. G. de Voogd and A. van der Linden. *Het Gas* **59**, 165–6(1939).—The smoke of tobacco has 2.6–3.2% CO for cigarets, 6.0–6.2% for cigars, up to 7.0% for pipe tobacco. The amt. of CO produced by 1 cigaret is around 300 cc. and 1 cigar 750 cc. These quantities are compared with what is produced by gas appliances and considered evidence to support the contention that small amts. of CO in the atm. are harmless. B. J. C. van der Hoeven

Sulfanilamide drugs. M. Nurmia. *Suomen Kemistil ehti* **12A**, 122–3(1939).—A review. S. A. Karjala

Aqueous extracts of crude drugs. M. M. Meyers. *Pharm. Weekblad* **76**, 1099–1128(1939).—The chem. and phys. properties were detd. for a no. of infusions and decoctions prepd. from crude drugs by the methods official in Netherland Pharm. IV and V, and by a variety of unofficial methods. Decoctions of carrageen had pH of 6.4 and showed definite viscosity values; changing the pH to 4.3, 2.3 or 11.1 increased the viscosity. *Althaea* root decoctions had pH about 6.0; changes to 5.5 or 8.0 decreased viscosity. Leaves of *Uva ursi* contained about 7.6% arbutin and 0.2% hydroquinone. Decoctions and infusions had pH values of about 4.9. Changes to pH values of 6.8 to 7.7 did not cause significant alterations. Data on ergot will be presented in a subsequent paper. Infusions of digitalis powder with water had lethal doses

of 20.97 cc. per kg. by the cat method; prepd. in the presence of 0.1% $CaCO_3$, 19.91 cc. (0.5% infusions). These corresponded to 102.2 mg. per kg. for the powder. By the Swiss Pharmacopoeial method, the infusion from this powder corresponded to 85.2 and to 94.9 mg. per kg. Infusions from a second powder by the Netherland Pharm. V method gave values of 88.7 and 77.6 mg. per kg. Studies were made on these same infusions by the heart-weight method and by the chem. methods, with similar results. In studies on senna leaves, the EtOH, MeOH and acetone fractions had cathartic effects on mice. The Netherland Pharm. V infusions had pH values of about 5.45–5.78, and decoctions 5.62. The infusions contained about 30 mouse units per g. and these values were not changed by increasing the pH to 7.8; more alk. solns. were weaker. The folliculi were less potent than the leaves. The infusions and decoctions of cortex chinae showed pH values between 3.0 and 5.4, according to the method of prepn. The total alkaloids varied from 28 to 81.5% of theory and were not assocd. with the pH values. Decoctions made with dil. HCl were most satisfactory. Infusions and decoctions of ipecacuanha contained 86 to 100% of the theoretical total alkaloids. The hemolytic index for a series of 10% decoctions of senega ranged from 1 1500 to 1 3000 and the pH approached 7.8. An infusion of condurango bark obtained by 24-hr. maceration contained 83% of the coldurangin. James C. Munch

The evaluation of germicides by the manometric method. J. O. Ely. *J. Bact.* **38**, 391–400(1939).—Manometric studies of the effects of several germicides on the O consumption of *Es. coli* in a synthetic medium were made and compared with the lethal effects as shown by subsequent cultures. A complete inhibition of respiration was found necessary to render the organisms incapable of growth when subcultured. Neg. cultures always resulted as soon as the respiration reached 0. When germicides were added to suspensions of *Es. coli* the percentage of inhibition of respiration increased during each successive observation until a max. was reached. In none of the cases did the effect recede from the max. The amt. of inhibition of respiration by sulfanilamide without a killing effect was greater than that for merthiolate. John T. Myers

Japanese peppermint oil. IX. Oil of Japanese Mentha viridis L. var crispa Benth. 2. Carvone. Tetu Nagasawa. *Repts. Osaka Imp. Ind. Research Inst.* **19**, No. 4(1938); cf. *C. A.* **32**, 8075⁵. *l*-Carvone, $C_{10}H_{14}O$ (I), obtained from Japanese *Mentha viridis* L. var crispa Benth, b_6 91–2°, d_4^{15} 0.9543, $[\alpha]_D^{15}$ −62.87°; semicarbazone, $C_{11}H_{17}ON_3$, m. 162.3°, $[\alpha]_D^{15}$ −84.28°; oxime, m. 72.8°, $[\alpha]_D^{15}$ −29.61°. Catalytic hydrogenation of I (I_2 + H_2) gave *l*-carvotanacetone (XII), $C_{10}H_{16}O$, b_6 88–8.5°, $[\alpha]_D^{15}$ −60.57°; semicarbazone, m. 173–4°, $[\alpha]_D^{15}$ −16.63°; oxime, m. 76–7°, $[\alpha]_D^{15}$ −10.44°. Reduction of I with Zn gave *d*-dihydrocarvone (II), b_6 87–7.5°, $[\alpha]_D^{15}$ 18.35°; semicarbazone, $C_{11}H_{19}ON_3$, one m. 145–50°, $[\alpha]_D^{15}$ −38.20° (85.7% yield), and another m. 190.1°, $[\alpha]_D^{15}$ 18.91° (11% yield); oxime, m. 88.9°, $[\alpha]_D^{15}$ 14.57° (in $CHCl_3$). Catalytic hydrogenation of I (I_2 + $2H_2$) gave *d*-carvomenthone (III), $C_{10}H_{18}O$, b_6 83–4° (87.2% yield), $[\alpha]_D^{15}$ 17.15°; semicarbazone, $C_{11}H_{21}ON_3$, one (IV) m. 192–3°, $[\alpha]_D^{15}$ 9.85° (in $CHCl_3$) (84.2% yield), and another (V) m. 160–4°, $[\alpha]_D^{15}$ 43.58° (11.6% yield); oxime, m. 98–9°, $[\alpha]_D^{15}$ 36.58° (in alc.) (80% yield). Hydrolysis of 10 g. IV and 4 g. V with oxalic acid gave *d*-β-carvomenthone, $C_{10}H_{18}O$, b_6 87–8°, $[\alpha]_D^{15}$ 11.80° (6.5 g. yield crude), and *d*-α-carvomenthone, b_6 88.9°, $[\alpha]_D^{15}$ 42.05° (yield 3 g. crude). Catalytic hydrogenation of II (II + H_2) gave *d*-carvomenthone (2), $C_{10}H_{18}O$, b_5 83–3.5°; $[\alpha]_D^{15}$ 19.79°. The properties of the semicarbazone and oxime are the same as above. Reduction of XII with Zn and alkali gave *d*-carvomenthone (3), $b_{3.5}$ 76–7°, $[\alpha]_D^{15}$ 16.34° (2 forms of semicarbazone and oxime were prepd.). Reduction of I with (iso-PrO)$_3$Al gave carveol (VI), $C_{10}H_{18}OH$, b_4 96–7°, $[\alpha]_D^{20}$ −109.0°; phenylurethan, one m. 71–2°, $[\alpha]_D^{15}$ −80.49° (90% yield) and another m. 60–3°, $[\alpha]_D^{15}$ −70.49° (10% yield); *p*-nitrobenzoate, m. 58–60 and 84–5°, on hydrolysis gave *l-trans*-carveol, b_4 96–7°, $[\alpha]_D^{15}$ −194.2°. Catalytic hydrogenation of VI gave *l*-carvotanacetol (1) (VII), $C_{10}H_{17}OH$, b_6 99–100°, $[\alpha]_D^{15}$ −75.27°, which gave 2 forms of *p*-nitrobenzoate and phenylurethan. Reduction of XII with (iso-PrO)$_3$Al gave VII. Reduction of I with Na and alc. gave *l*-dihydrocarveol (XI), $C_{10}H_{18}O$, b_4 89–90°, $[\alpha]_D^{15}$ −29.07, which gave 2 forms of phenylurethan and *p*-nitrobenzoate. Catalytic hydrogenation of I (I + $3H_2$) gave *d*-carvomenthol (1) (VIII), $b_{5.5}$ 92.5–3.5°, $[\alpha]_D^{15}$ 31.40°, and *p*-menthane as by-product. VIII gave 2 forms of phenylurethan and *p*-nitrobenzoate. Catalytic reduction of II (II + $3H_2$) gave *d*-carvomenthol (2) (IX), $C_{10}H_{19}OH$, b_6 88–9°, $[\alpha]_D^{15}$ 23.90°, which gave 2 forms of phenylurethan and *p*-nitrobenzoate. IX and anhyd. phthalic acid gave 2 forms of ester, one m. 121–2°, $[\alpha]_D^{20}$ 55.76° (80% yield) and the other m. 88–90°, $[\alpha]_D^{20}$ −57.27° (10% yield). Hydrolysis of the former with alc. KOH gave *l*-neocarvomenthol, $C_{10}H_{20}O$, b_4 95–7°, $[\alpha]_D^{15}$ 41.21°. Catalytic reduction of *d*-carvomenthone (3) gave *d*-carvomenthol (3) (X), $C_{10}H_{19}OH$, b_{3-5} 82–3°, $[\alpha]_D^{15}$ 31.52°. X gave 2 forms of phenylurethan and *p*-nitrobenzoate. Catalytic reduction of XI gave *l*-carvomenthol (4), $C_{10}H_{19}OH$, b_5 89–90°, $[\alpha]_D^{15}$ −15.16°, which gave 2 forms of phenylurethan and *p*-nitrobenzoate. Hydrolysis of the *p*-nitrobenzoate (m. 54–5°) gave *l*-neoisocarvomenthol, $C_{10}H_{20}O$, b_4 87–8°, $[\alpha]_D^{20}$ −32.42°. Catalytic reduction of VI gave *d*-carvomenthol (5), $C_{10}H_{19}OH$, b_{4-5} 87–8°, $[\alpha]_D^{15}$ 12.54°. Catalytic reduction of VII gave *d*-carvomenthol (6), b_4 86–7°, $[\alpha]_D^{15}$ 13.31. Reduction of XII with Na and alc. gave *l*-carvomenthol (7), b_5 88–8.5°, $[\alpha]_D^{15}$ −25.05. Reduction of III with Na and alc. gave *l*-carvomenthol (8), $b_{4.5}$ 85–6°, $[\alpha]_D^{15}$ −15.06°. Reduction of II with Na and alc. gave *l*-carvomenthol (9), $b_{5.5}$ 91.5–2, $[\alpha]_D^{15}$ −13.90°. Reduction of *d*-carvomenthone (3) with Na and alc. gave *l*-carvomenthol (10), b_6 89–9.5°, α_D^{15} −15.07°. Reduction of III with (iso-PrO)$_3$Al gave *l*-carvomenthol (11), b_{5-6} 94.5–9.5°; $[\alpha]_D^{15}$ −7.05°. Reduction of II with (iso-PrO)$_3$Al gave *l*-carvomenthol (12), b_6 95–6°, $[\alpha]_D^{15}$ −6.98°. All these carvomenthols gave 2 forms of phenylurethan and *p*-nitrobenzoate. The use of these compds. is also given. F. I. Nakamura

Methods of analysis of sulfanilamide. R. W. Towne and R. M. Hitchens. *J. Am. Pharm. Assoc.* **28**, 585–8 (1939).—Two simple, rapid and accurate dets. for the assay of sulfanilamide are described. Detn. of the crystg. point (technique described in detail) will detect as little as 0.1 mol. % of sol. impurities, including isomers and other amino compds. The following technique is recommended for the diazotization titration: place 3.4 g. of sample in a 250-cc. beaker, add 20 cc. of concd. HCl and 80 cc. H_2O, cool to 0–5°, add a few crystals of KBr (as catalyst) and about 20 cc. of chipped ice; place the beaker in an ice-bath, insert this mixt. under a mech. stirrer and the electrode system bright Pt-0.1 *N* KCl-AgCl-Ag; place the buret tip beneath the surface of the soln. and add about 38 cc. of 0.5 *N* $NaNO_2$ soln., taking approx. 2 min. for the addn.; from this point read the potential after each 0.05 cc. addn. of reagent; calc. the difference in potential for each addn.; the largest change in potential (at about 425–525 mv.) occurs at the end point. Percentage of sulfanilamide = (cc. 0.5 *N* $NaNO_2$ × 0.0860 × 100)/(wt. of sample). The titration is accurate to 0.1%; the potentiometer may be replaced by starch-iodide indicator with little, if any, loss in accuracy. These 2 dets. combined are a precise method for estg. the purity of sulfanilamide. A. Papineau-Couture

The volatile oil of Comptonia asplenifolia. Romulus De Nicolas and E. V. Lynn. *J. Am. Pharm. Assoc.* **28**, 588–9(1939).—Distn. of fresh leaves and stems of *Comptonia asplenifolia*, Aiton (Myricaceae) gave a total of 31.5 g. (0.054% on the fresh material, 0.14% on the dry basis) of a yellowish brown oil with a cinnamon-like odor, d_{20}^{20} 0.9154, n_{20} 1.4870, congealing point about 5°, acid value 14.04, ester value 13.30, sapon. value after acetylization 58.66. The oil contained about 20% of terpenes, a considerable amt. of cineole and small quantities of esters and alcs., but no aldehydes nor ketones. AcOH and small amts. of unidentified acids and lactones were present.

le chief constituents were high-boiling and may include caryophyllene. A. Papineau-Couture

A comparative study of the three recognized assays for oil of chenopodium. Wm. F. Reindollar. *J. Am. Pharm. Assoc.* 28, 589–91(1939).—A comparative study of the A. O. A. C., B. P. and U. S. P. assays for wormseed oil made upon authentic samples showed that the 2 former methods yield results concordant with each other, but at variance with those obtained by the U. S. P. procedure, which is sometimes higher and sometimes lower than of the 2 other methods. Although aging of wormseed oil results in an increase in d. and alc. soly. and a decrease in ascaridole, the general relationship existing among these factors remains unchanged. A. Papineau-Couture

The heavy-metal test of the U. S. P. M. W. Carey and R. E. Schoetzow. *J. Am. Pharm. Assoc* 28, 592–3 (1939).—The U. S. P. makes no distinction between the heavy-metal test as applied to inorg. and org. substances. It is shown that, in order to obtain reliable results when the test is applied in presence of org. matter, the latter should first be destroyed, and it is recommended that the most suitable method of effecting such destruction should be studied and incorporated in the U. S. P. test.
A. Papineau-Couture

Drug extraction. XXII. The extraction of podophyllum. Wm. J. Husa and D. W. Lee. *J. Am. Pharm. Assoc* 28, 593–7(1939); cf. *C. A.* 33, 3177.—Podophyllum was extd. by various methods. In maceration with an excess of alc., equil. was reached in 36 hrs. By percolation in cylindrical Pyrex glass tubes, the 1st 250 cc. of percolate from 250 g. of drug contained 85 90% of the total resin of the drug. In a method of forcing the menstruum through a long column of drug by means of air pressure, as much as 99% of the resin was obtained in the first 1000 cc. of percolate from 1000 g. of the drug.
A. Papineau-Couture

Hydrogenated castor oil as an ointment base. IV. Hydroxystearic acid. Geo. W. Fiero. *J. Am. Pharm. Assoc.* 28, 598–602(1939); cf. *C. A.* 33, 3072[5].—Salts of hydroxystearic acid obtained from completely hydrogenated castor oil were prepd. and their characteristics reported. Emulsions and cold creams compared with those prepd. with ricinoleic or stearic acids. Vanishing creams were prepd. with hydroxystearic acid and with mixts. of hydroxystearic and stearic acids. Alkylolamine salts of hydroxystearic acid were superior emulsifying agents compared with those of ricinoleic acid and practically equal to those of stearic acid. A. Papineau-Couture

The assay of digitalis. I. Criteria for evaluating various methods using frogs. Lloyd C. Miller, Chester I. Bliss and Herbert A. Braun. *J. Am. Pharm. Assoc.* 28, 644–57(1939).—Further improvements in the digitalis assay on frogs can be facilitated by objective criteria for testing the effectiveness of any proposed modification of procedure. Owing to the nature of the assay, such criteria are necessarily statistical in character and in a well-designed expt. can be computed from the data of a self-contained assay. By transformation of dosages to logs and of percentage effects to probits, the sigmoid dosage-response curves for the 2 materials or procedures involved in the test are fitted by parallel straight lines; then the horizontal distance between them measures with a calculable precision the log-ratio of their potencies, $M \pm S_M$. The computation of these and related parameters is illustrated with a numerical example. Methods are described for increasing the precision of M by an efficient design of the individual assay, by utilizing past experience relative to the slope of the standard curve where applicable and by combining the results of replicated assays to obtain a more precise weighted mean log-ratio of potencies. On the above statistical basis, 4 criteria are proposed for evaluating an assay procedure: (*a*) a value of χ^2 which indicates that the several groups of frogs used in the test were homogeneous and comparable, (*b*) a consistent and relatively steep slope of the parallel dosage-effect curves, (*c*) a consistently low value of the standard error of the log-ratio of potencies, S_M, and (*d*) agreement of replicate detns. of M within the sampling error. In conjunction with a knowledge of the practicability and exptl. objectivity of a procedure, these criteria should be conclusive in the development of an improved technique. These criteria were applied in a comparison of the effects produced by injection of the same sample of digitalis in test dilns. contg. 5 and 23% alc. The apparent potencies of the U. S. P. XI reference digitalis powder and of the International 1926 and 1936 standard digitalis powders were not influenced by this 4-fold change in the alc. content of the injected test dilns., the same digitalis powder when injected with 5% alc. exhibiting a potency of 103 ± 2.54% of that exhibited when injected with 23% alc. The relative effectiveness of digitalis injected intramuscularly was compared with that injected in the lymph sac. One hr. after injection the effective absorption of U. S. P. XI reference digitalis powder from the lymph sac was about one-half that from the thigh muscles and even overnight the potency of digitalis was slightly but significantly greater (106.5 ± 2.3%) by the intramuscular route than via the lymph sac. The difference was less pronounced with the 1936 International standard powder. The overnight assays showed a smaller standard error than the 1-hr. tests because of a consistently steeper dosage-effect curve. A. Papineau-Couture

A comparative study of tannic acid, U. S. P. Clifton E. Miller and L. W. Rising. *J. Am. Pharm. Assoc.* 28, 658–9(1939).—The U. S. P. XI tests for purity were applied to 11 com. samples of fluffy tannic acid, and the wide variation in the results showed that this product is of variable compn. Efforts to develop an assay of tannic acid using m. p., n, surface tension, α, titratable acidity, spectroscopic analysis and color reactions were unsuccessful. A. Papineau-Couture

The volatile oil of Poliomintha incana. A. F. Sievers and C. G. Marshall. *J. Am. Pharm. Assoc.* 28, 659–61 (1939).—Distn. of 53 lb. of dry herb yielded 187 g. (0.78%) of light-brown oil with minty, pennyroyal-like odor, d_{25} 0.9339, sol. in all proportions in 95% and in 80% alc., sol. in 1.5 vol. of 70% alc., α_{25} 17.2° (100-mm. tube), acid no. 2.11, sapon. no. 23.3, Ac no. 42.5. Fractional distn. at atm. pressure indicated that the principal constituent of the oil is pulegone. A. Papineau-Couture

Report on (the analysis of) drugs. L. E. Warren. *J. Assoc. Official Agr. Chem.* 22, 695–706(1939); cf. *C. A.* 33, 1097[1]. A discussion of the reports of the associate referees (cf. following abstracts) of revisions which might be advisable in the status of some of the present tentative and official A. O. A. C. methods for the detn. of drugs, and of new subjects which are recommended for investigation by the Assocn. A. Papineau-Couture

Report on microchemical tests for alkaloids. C. K. Glycart. *J. Assoc. Official Agr. Chem.* 22, 706–9(1939); cf. *C. A.* 33, 1097[2].—Collaborative study of microchem. tests for berberine-HCl (addn. of HCl to a 1:200 or 1:400 soln. of the alkaloid), cotarnine (H_2PtCl_6, $HgCl_2$, $K_4Fe(CN)_6$), narceine (H_2PtCl_6, Wagner's or other iodized reagents gives characteristic blue crystals) and narcotine (liberation of the free acid by alkali such as KOH or preferably NH_4OH) gave satisfactory results, and adoption of the tests as tentative is recommended. The technique of the tests and description of the crystals are given in detail in *J. Assoc. Official Agr. Chem.* 22, 88.
A. Papineau-Couture

Report on microchemical methods for (the identification of) synthetics. Irwin S. Shupe. *J. Assoc. Official Agr. Chem.* 22, 709–12(1939); cf. *C. A.* 33, 1097[3].—A collaborative study of microchem. tests for the identification of diallylbarbituric acid (addn. to the dry powder of $Pb(OAc)_2$ in soln. in triethanolamine, addn. of $Ba(OH)_2$ to the dry powder), mandelic acid (addn. of $Pb(OAc)_2$ or $HgNO_3$ soln. to a 1% aq. soln. of the drug), and sulfanilamide (addn. of benzaldehyde to the dry powder or of $NaNO_2$ soln. to a satd. soln. of the drug in 0.1 N HCl) gave satisfactory results, and adoption of the tests as tentative is recommended. A. Papineau-Couture

Report on (the determination of) hypophosphites (in pharmaceutical preparations). Henry R. Bond. *J. Assoc. Official Agr. Chem.* 22, 712–15(1939); cf. *C. A.*

33, 1097⁵.—A collaborative study of the Bruening Br oxidation method (*C. A.* 30, 2702⁶) adopted for the detn. of hypophosphites in Sirup NH_4 Hypophosphites, Sirup Hypophosphites and Sirup Hypophosphites Comp. gave results in good agreement with the calcd theoretical. Investigation of the reducing action of the nonhypophosphite ingredients of these sirups showed no reducing action by glycerol and Na citrate, and slight reducing action by sucrose and quinine and strychnine; the effect of these ingredients on the Br reagent is so small, however, that it falls within the limits of exptl. accuracy. Results of assays of sirups made 7 months after compounding were as close to the theoretical figure as those obtained from assays of the freshly prepd. sirups, indicating no oxidation of the hypophosphites had occurred. In the Bruening assay, standard bromide-bromate soln. (3 g. $KBrO_3$ and 12 g. KBr per l.) can be used instead of 0.1 *N* Br.

A. Papineau-Couture

1 **Report on daphnia methods.** Arno Viehoever. *J. Assoc. Official Agr. Chem.* 22, 715–18(1939); cf. *C. A.* 33, 1097⁷.—Suggested tentative techniques are described for approx. assays for cannabis (marihuana), approx. bioassay for vitamin E and tocopherols, bioassay for aphrodisiacs and irritants, and bioassay of toxic substances, with daphnia as a biol. reagent. A. Papineau-Couture

2 **Report on (the determination of) hexylresorcinol (in pharmaceutical preparations).** Morris L. Yakowitz. *J. Assoc. Official Agr. Chem.* 22, 719(1939); cf. *C. A.* 33, 1097⁸.—Assay by the previously described method of the same olive-oil soln. of hexylresorcinol after aging for about 1 yr. gave a 96.3% recovery. Investigation indicated that the use of hydrazine in the method may be unnecessary. A. Papineau-Couture

3 **Report on (the determination of) ergot alkaloids.** Lloyd C. Miller. *J. Assoc. Official Agr. Chem.* 22, 719 (1939); cf. *C. A.* 33, 1098¹.—In the previously described colorimetric method extn. of crude ergot in a Soxhlet extractor by the U. S. P. menstruum (Process C percolation with acidified 50% alc.) removes only 50–75% of the amt. of alkaloid that can be extd. with Et_2O.

A. Papineau-Couture

4 **Report on (the determination of) nitroglycerin in (medicinal) mixtures.** Omer C. Kenworthy. *J. Assoc. Official Agr. Chem.* 22, 719–20(1939); cf. *C. A.* 33, 1098³.—The previously described method appeared to be satisfactory, but when submitted to collaborators the results showed shortages of about 30%. Attempts to modify the method to obtain better recovery were unsuccessful.

A. Papineau-Couture

5 **Report on (the determination of) guaiacol.** Kenneth L. Milstead. *J. Assoc. Official Agr. Chem.* 22, 721–2 (1939); cf. *C. A.* 33, 1098⁵.—A collaborative study of the Viebock and Schwappach method, as modified by Clark (*C. A.* 26, 2395), for the detn. of alkoxy groups and for the estn. of guaiacol carbonate and guaiacol gave satisfactory results, and its adoption as tentative is recommended. A. Papineau-Couture

6 **Report on (the assay of) iodine ointment.** Wm. F. Reindollar. *J. Assoc. Official Agr. Chem.* 22, 722–3 (1939); cf. *C. A.* 33, 1098⁶.—A collaborative study was made of the present tentative method for I and the proposed method for organically combined I; a freshly prepd. ointment and one that was 4-yrs. old were used. Results for I by the tentative method were satisfactory, and adoption of the method as official is recommended. Good agreement was obtained for organically combined I in the freshly prepd. ointment, but not in the older sample.

A. Papineau-Couture

7 **Report on the separation of acetylsalicylic acid, acetphenetidin and caffeine.** Donald C. Grove. *J. Assoc. Official Agr. Chem.* 22, 723–6(1939).—A method has been worked out (technique described in detail in *Ibid.* 91) using sepn. of acetylsalicylic acid from acetphenetidin and caffeine by means of $NaHCO_3$; the acetphenetidin and caffeine are then treated with dil. H_2SO_4 which removes all the caffeine plus a small quantity (usually about 75 mg.) of acetphenetidin, leaving the main bulk of the latter behind; the caffeine is then sepd. from the remaining acetphenetidin by means of the acid hydrolysis method. Results of a collaborative study of the method showed agreement between collaborators which is believed to be as satisfactory as could be expected in a mixt. of this type, and adoption of the method as tentative is recommended.

A. Papineau-Couture

8 **Report on (the identification of) gums in drugs.** J. H. Cannon. *J. Assoc. Official Agr. Chem.* 22, 726–8(1939).—A collaborative study was made of the identification of Irish moss, tragacanth, agar, quince, karaya and galagum by means of chlorzinc iodide (to 100 cc. of a soln. of $ZnCl_2$, d. 1.8, add a soln. of 10 g. KI and 0.15 g. I in 10 cc. H_2O; keep a few crystals of I in the soln.), tincture of I (U. S. P.), ruthenium red (to a few cc. of a 10% soln. of $Pb(OAc)_2$ add enough ruthenium red to produce a wine-red color), methylene blue (0.1% soln. in alc., 0.1% soln. in H_2O). The technique of the test and reactions obtained with the several reagents are described in detail in *Ibid.* 92–4. The results were satisfactory and adoption of the method as tentative is recommended.

A. Papineau-Couture

9 **Report on (the determination of) theobromine in the bromine calcium tablets.** P. S. Jorgensen. *J. Assoc. Official Agr. Chem.* 22, 729–30(1939); cf. *C. A.* 33, 1099¹.—A collaborative comparison of the previously described proposed acidimetric method and of the present tentative A. O. A. C. iodometric method showed that the iodometric method gives varying results, while the acidimetric method gives consistent results in the hands of different analysts. It is therefore recommended that the latter method replace the present tentative method.

A. Papineau-Couture

10 **Report on (the determination of) chlorobutanol.** Frank C. Sinton. *J. Assoc. Official Agr. Chem.* 22, 730–2 (1939); cf. *C. A.* 33, 1099⁴.—A collaborative study was made of the previously described method for the assay of chlorobutanol and of its detn. in soln. with some modifications of the details of the distn. (technique described in detail in *J. Assoc. Official Agr. Chem.* 22, 95). For the chlorobutanol crystals the recovery averaged 99.5%; for the soln., 98%. The majority reported no difficulty with the method, which is recommended for adoption as tentative. A. Papineau-Couture

11 **Report on (the analysis of) phenolphthalein and acetylsalicylic acid (mixtures).** Geo. M. Johnson. *J. Assoc. Official Agr. Chem.* 22, 732–4(1939); cf. *C. A.* 33, 1099⁶.—The technique of the previously described method was improved (described in *J. Assoc. Official Agr. Chem.* 22, 95–6). Collaborative study of the improved method gave 96.4–100.6% (av. 98.7%) recoveries of acetylsalicylic acid and 96.2–103.2% (av. 101.0%) recoveries of phenolphthalein. Its adoption as tentative is recommended.

A. Papineau-Couture

12 **Report on (the determination of) aminopyrine and phenobarbital in mixtures.** E. C. Payne. *J. Assoc. Official Agr. Chem.* 22, 735–6(1939); cf. *C. A.* 33, 1100³.—A study on individually weighed samples of the phenobarbital and aminopyrine (without excipients) of the previously described method gave recoveries of 99.6–100.7% and 99.3–99.5%, resp. A method based on extn. of phenobarbital from acid soln. (1 + 9 H_2SO_4) with $CHCl_3$ or Et_2O and later removal of aminopyrine after making alk. with NH_4OH gave incomplete sepn. of the phenobarbital; but further extn. of the original acid soln. with solvent yielded no more ext., which might be explained by a slight interaction between aminopyrine and phenobarbital. A somewhat different technique in which the aminopyrine is extd. as above but the phenobarbital is extd. in a continuous extractor with $CHCl_3$ as solvent gave 100.1–100.3% recovery for aminopyrine and 100.4% for phenobarbital.

A. Papineau-Couture

13 **Report on (the analysis of) terpinol hydrate and codeine.** Jonas Card. *J. Assoc. Official Agr. Chem.* 22, 736–8 (1939); cf. *C. A.* 33, 1100⁹.—The previously described method was modified by providing spontaneous evapn. of the alc.-$CHCl_3$, instead of evapn. in a slow current of air. Collaborative study of the modified method gave better

results than the previous yr., and its adoption as tentative is recommended. A. Papineau-Couture

Report on (the analysis of) emulsions (of cod-liver oil). W. F. Kunke. *J. Assoc. Official Agr. Chem.* **22**, 739–42 (1939); cf. *C. A.* **33**, 1101[1].—A description is given of the development of a method (technique described in detail in *J. Assoc. Official Agr. Chem.* **22**, 96) of detg. cod-liver oil in emulsions, which consists essentially in mixing an amt. of sample contg. about 2 g. of oil with about 10 g. of finely powd. $CaCO_3$, extg. with successive portions of $CHCl_3$ till the last portion exts. not more than 1 mg., evapg. the ext. in a tared beaker on a steam bath and allowing to remain on the bath for about 10 min. after the odor of $CHCl_3$ has disappeared, and drying at 100 to const. wt. (weighing to be made at 5-min. intervals). Collaborative study of the method gave recoveries of 99.5–100.2%. Adoption of the method as tentative is recommended. A. Papineau-Couture

Report on (the assay of) ointment of mercuric nitrate (citrine ointment). H. O. Moraw. *J. Assoc. Official Agr. Chem.* **22**, 743–8(1939); cf. *C. A.* **33**, 1101[2].—Minor changes were made in the directions of the previously described method (modified technique described in detail in *J. Assoc. Official Agr. Chem.* **22**, 96–7) with a view to improving its accuracy. Collaborative study of the revised method showed an av. recovery of 99.7% of the Hg, and it is recommended the method be adopted as official. A. Papineau-Couture

Report on (the determination of) sulfanilamide. Edward M. Hoshall. *J. Assoc. Official Agr. Chem.* **22**, 748–57(1939).—Two methods were developed for the detn. of sulfanilamide. (*1*) *Bromination method:* Place a portion of the sample contg. 0.1–0.3 g. sulfanilamide in a 500-cc. glass-stoppered I-absorption flask, add about 25 cc. H_2O and sufficient 0.1 *N* or 0.5 *N* bromide-bromate soln. to ensure a 10–50% excess of Br; add rapidly 10 cc. of HCl and immediately stopper, swirl the flask, place in the dark for about 5 min., remove the stopper just sufficiently to introduce quickly 10 cc. of 10% KI soln. (avoid escape of Br vapors), stopper, shake thoroughly, remove the stopper, rinse it and the neck of the flask, add about 150 cc. H_2O and titrate with 0.1 *N* $Na_2S_2O_3$, using starch indicator; 1 cc. 0.1 *N* bromide-bromate soln. = 0.004305 g. sulfanilamide. (*2*) *Hydrolysis method:* Place on a 9-cm. folded filter paper in a funnel a portion of the sample contg. about 0.5 g. of sulfanilamide; wash the sol. portion with a fine stream of Me_2CO into a 250-cc. flask, using a total of about 25 cc. of Me_2CO (test for complete extn.), remove the Me_2CO by immersing the flask in water at about 70°, remove from the bath, add 10–12 cc. of 75% (by vol.) H_2SO_4, reflux for 30 min., dil. to about 100 cc., add excess of 50% alkali, distil, collect the NH_3 in excess of 0.1 *N* H_2SO_4 and titrate with 0.1 *N* NaOH, using methyl red indicator; 1 cc. 0.1 *N* acid = 0.01722 g. sulfanilamide. Attempts to develop a method based on reaction with HBrO and formation of a relatively stable sulfondibromamide were unsuccessful. In a collaborative study, the bromination method consistently gave somewhat high results, and investigation of several factors that might be conducive to the production of such excesses disclosed points whereby the method could be modified to give quant. yields. The results of a collaborative study of the hydrolysis method were more satisfactory; they were slightly high, but the av. appeared to be within the analytical error for a detn. of this nature. The method is recommended for adoption as tentative. A. Papineau-Couture

Report on (the determination of) mandelic acid. H. G. Underwood. *J. Assoc. Official Agr. Chem.* **22**, 757–61 (1939).—Two qual. tests for mandelic acid and a method for its detn. in tablets and liquid prepns. were developed and submitted to collaborative study. Addn. of a little 10% $FeCl_3$ soln. to a 2.5% soln. of mandelic acid produces a bright yellow color (general test for hydroxy acids, and not specific for mandelic acid). To 5 cc. of aq. 5% mandelic acid soln. add 5 cc. H_2SO_4, agitate, add 10 cc. H_2SO_4 so as to form 2 layers; a purple color slowly forms at the interface if the test tube is allowed to stand a few min., and a strong odor of benzaldehyde is noticed on shaking. The detn. is based on extg. from acid soln. with a 2 + 1 $CHCl_3$-Et_2O mixt. (7 × 20 cc. usually suffices), evapg. at not over 40° with the aid of a fan, dissolving in CO_2-free water and titrating with 0.1 *N* NaOH with phenolphthalein indicator. The collaborative study gave satisfactory results and adoption of the tests and method as tentative is recommended. A. Papineau-Couture

Report on (the determination of) chloroform in mixtures. John R. Matchett. *J. Assoc. Official Agr. Chem.* **22**, 761–4(1939).—A study of the present tentative A. O. A. C. method (cf. *C. A.* **25**, 5643) showed that: (1) use of the present alkali reagent is satisfactory; (2) the use of 0.1 g. (instead of 1 g.) $CaCO_3$ is satisfactory; (3) carborundum chips are very useful to prevent "bumping" during distn.; (4) the method may be relied upon to show at least 98% recovery of $CHCl_3$ present in the sample; (5) as much as 5% of the $CHCl_3$ present may be lost on pipeting a sample of heavy sirup; (6) by use of special app. recovery might be increased and more concordant results obtained. A. Papineau-Couture

Vitamin A in ling cod-liver oil. L. B. Pett, Marian Lipkind and G. A. LePage. *Nature* **144**, 634(1939).—Absorption curves are given for ling cod-liver oil, Pacific whale oil and for av. halibut- and cod-liver oils. Ling cod-liver oil has a typical absorption around 328 mμ (vitamin A), and is more potent than halibut-liver oil. E. D. Walter

Modern chemistry, modern medicine and modern food (Dodds) **2**. Polarographic method for detg. org. peroxides [in studying pharmaceutical prepns.] (Dobrinskaya, Neĭman) **7**. Characterization of acetylsalicylic acid prepns. (Kruger) **7**. Chem. microscopy of some toxicologically important alkaloids (Whitmore, Wood) **7**. Regulations on coal-tar colors [suitable for drugs and cosmetics] (Anon.) **12**. Soybean-oil foots manuf. of lactation-promoting medicine (Okano, *et al.*) **27**. Separatory flask for extg. alkaloids (U. S. pat. 2,170,411) **1**.

Extracting carotenoids. David D. Peebles. U. S. 2,170,872, Aug. 29. A material such as macerated fresh carrots is digested with alkali under superatm. pressure and at a temp. substantially above 100° and the pressure is then rapidly released and the digested material is subjected to solvent extn. (suitably with "mineral spirits") for removal of carotenoids.

Extraction of saponins from vegetable materials. Frederick H. Waltz (to Eastman Kodak Co.). U. S. 2,172,265, Sept. 5. Vegetable material contg. a saponin, such as soap bark, soapwort or soaproot, is extd. with a solvent such as MeOH which is substantially free from water, in the presence of an alk. compd. such as NH_3 (suitably with heating to the b. p. and filtration while hot).

Dissolving α-naphthol in water. Ferdinand Herb (to Arnold Joerns). U. S. 2,171,555, Sept. 5. For use with water to form antiseptic solns., a concd. soln. is prepd contg. K soap, some water, α-naphthol and an alc. such as iso-Pr alc., the proportion of soap to α-naphthol being at least about 3 to 1 and the soln contg. at least about 20% of the alc. Acetone or $CHCl_3$ also may be used.

Menthyl anthranilate. Marion S. Carpenter (to Givaudan-Delawanna, Inc.). U. S. 2,170,185, Aug. 22. Menthyl anthranilate, b$_3$ 177–9°, may be prepd. by treating a menthol soln. of an alkali metal mentholate with methyl anthranilate. It is suitable for use in cosmetics such as "suntan creams" or "sunburn lotions" as an absorbent of actinic rays.

Disabling liquid suitable for temporary blinding. Charles E. Howett (to Howett Laboratories, Inc.). U. S. 2,171,791, Sept. 5. NH_4 carbonate is used with aq. NH_3 soln., alc., essential oils such as those of lemon, lavender and myristica, and oil of trefle which serves to prevent burning or blistering of tissue in the eye socket.

Molded spheres or ovoids, etc., containing vitaminic liquids. James A. Raynolds, Jr. (to Atlantic Coast Fisheries Co.). U. S. 2,170,520, Aug. 22. App. is de-

scribed, and a mode of operation for prepg. spherical, spheroidal, ovoidal and similarly shaped articles for pharmaceutical and other purposes, and comprising a colloidal matrix having dispersed therein a vitamin-bearing liquid completely enveloped and imprisoned by the colloidal matrix so that there is no free vitamin-bearing liquid on the surface of the product. Gelatin compns. mixed with vitamin C may be used.

Vaccines, etc. Chemische Fabrik vorm. Sandoz. Brit. 506,095, May 23, 1939. Material for inoculation purposes is prepd. by freeing cultures of bacteria, etc., from H_2O by exposure to a high vacuum at below 0° and killing the bacteria, etc., in the moisture-free state by treatment with anhyd. cell poisons or radiations of short wave lengths. Among examples, *Staphylococci* are, after being frozen and dried, killed by a soln. of HCN in C_6H_6.

Antitoxins against bacterial toxins, from the liver and spleen. Carl L. Lautenschlager and Willy Ludwig (to Winthrop Chemical Co.). U. S. 2,171,320, Aug. 29. Slightly acid autolyzed spleen or autolyzed liver is extd. with water or a water-sol. org. solvent of low mol. wt. such as MeOH or with an aq. mixt. of such an org. solvent, and the soln. thus formed is treated with a "ballast-eliminating" heavy-metal compd. such as Fe dialysate and the resulting product is further purified by use of a water-sol. org. solvent such as MeOH (all steps of the process being carried out at a temp. below about 40°).

Antipoliomyelitis serum. John A. Toomey (to Western Reserve University). Brit. 507,376, June 14, 1939. The serum is obtained by immunizing an animal by successive injections of poliomyelitis virus fortified with products of metabolism of intestinal bacteria and obtaining a serum from the blood of the animal. A soln. of the virus in normal saline with which the fortifying material is to be admixed may be obtained by adsorbing the virus on $Al(OH)_3$ gel and eluting the adsorbed virus.

Disinfectant and cleansing compositions. Günther Parizot. Brit. 506,451, May 30, 1939. Tablets for use in cleansing and disinfecting artificial dentures placed in H_2O are made by compressing a mixt. of Na_2O_2 about 2 and NaCl about 3 parts. A substance, e. g., Na phosphate, for pptg. hardening agents from hard H_2O may be added to the mixt. Other agents that do not decomp. Na_2O_2, e. g., Na_2CO_3, calcined soda, may be present.

Absorbent wadding suitable for surgical purposes. Hans Freudenberg (to Carl Freudenberg G. m. b. H.). U. S. 2,169,947, Aug. 15. Wadding consisting of absorbent collagenous fibers substantially free from water is formed of fibers produced by converting animal hide material into a swollen condition in which the fibers may be mechanically isolated, shredding and treating the resulting coarse fibrous material with water-miscible org. liquids such as alc. or acetone, and further finely shredding.

Perfumes containing ketals, etc. Albert Weissenborn (to Winthrop Chemical Co.). U. S. 2,169,984, Aug. 15. Various perfume mixts. are described, which have an odor similar to geranium oil, rose, jasmine or honey, and which contain ketals having 6 to 9 C atoms in the ketone residue, such as diisopropylpyrocatechol ketal, methylamylpyrocatechol ketal or diisobutylpyrocatechol ketal, in mixt. with various other compds.

Water-soluble capsules for cosmetic purposes. Karl W. Schmidt. U. S. 2,170,253, Aug. 22. Capsules for holding volatile products such as perfumes for use in bath water are made by forming urea into the shape of a capsule and then subjecting it to a pressure of at least 1000 kg. per sq. cm. to render the urea impervious to passage of the volatile products without destroying the soly. of the capsule in water.

Massage creams. Ida G. Blish. U. S. 2,172,118, Sept. 5. A high mol. wt. fatty acid such as stearic or palmitic acid is used with a soap such as the Na soap of a high-mol. fatty acid, together with a wax such as beeswax and ceresin, and sufficient readily volatile alc., etc., to produce a cream which is substantially fluent at body temps., and with a small proportion of a low-mol. fruit acid such as citric acid or HOAc to produce a surface film during use which rolls off the surface in the form of filaments.

Detergents in cake form for toilet purposes. Wm. G. Beckers. U. S. 2,169,829, Aug. 15. A mildly acid detergent of good lathering and cleansing properties is formed of boric acid (which serves as a binder) and the Na salt of the acid sulfuric acid ester of tech. lauryl alc. or other suitable water-sol. salt contg. an alkyl radical of at least 8 C atoms and radicals of sulfuric or phosphoric acid.

Bleaching tobacco. Hermann Baier (to Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler). U. S. 2,170,107, Aug. 22. Tobacco is first moistened with a soln. of H_2O_2 and is subsequently subjected to the action of a reducing agent such as glucose and tobacco sauce which reduces and destroys residual H_2O_2. Cf. *C. A.* **33**, 3974[4].

Cigaret paper. Paul Poetschke. U. S. 2,171,986, Sept. 5. The paper carries sufficient NH_4NO_3, urea nitrate, hexamethylenetetramine or a water-sol. amino acid that the burning paper yields an alk. smoke.

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

E. M. SYMMES

Borax—its manufacture and uses. E. M. Kitchen. *Am. Fertilizer* **91**, No. 7, 7–9, 24, 26(1939).—A review of the processes used in the manuf. of borax in the U. S., of the uses to which it is put in many industrial processes, of its value in promoting the healthy growth of crops on B-deficient soils and of methods of applying it to the soil.

W. H. Ross

Bores for brine in Sarjapur nala, Raichur district. L. S. Krishnamurthy and H. S. Krishnamurthy. *J. Hyderabad Geol. Survey* **3**, Pt. 2, 1–23(1938). Cf. *C. A.* **32**, 2468[4]. Details of 22 bores averaging 20–30 ft., along the bed of the Sarjapur nala, are given, with analyses of the brine obtained therefrom. The av. content, in lb./1000 gal., was NaCl 13, Na_2SO_4 3.76, $MgCl_2$ 0.52, $MgSO_4$ 6.67, $CaCO_3$ 1.02 and $CaSO_4$ 3.53. The economic possibilities are discussed.

C. A. Silberrad

The industrial extraction of krypton and xenon from the air, and a historical review of the industry engaged in the production of liquid air. Georges Claude. *Ice and Cold Storage* **42**, No. 497, 118(1939). The extn. of Kr from air by washing the cooled air with liquid air is discussed.

A. H. Johnson

Recovery of heat from the gases from roasting pyrite and burning sulfur. Rudolf Pitz. *Arch. Wärmewirt.* **20**, 107–9(1939). Heat-balance calcns. are presented to show the possibilities of heat recovery for these processes.

Ernest W. Thiele

Concentration of sulfuric acid. Willi Büsching. U. S. 2,172,058, Sept. 5. App. is described, and a process involving concg. the acid to about 94%, passing this acid through a wide introduction pipe into a closed vessel and introducing the acid at the bottom of the vessel, maintaining a substantial body of acid in the vessel surrounding the pipe and in heat-exchange relation with the acid in the pipe, heating the acid in the vessel, concg. the acid mainly in said pipe by regulating the heating and rate of introduction of the acid so that the acid leaving the introduction pipe is concd. to about 98%, withdrawing acid from the vessel and withdrawing vapors from the heated acid through the introduction pipe.

Concentrated nitric acid. Rudolf Wendlandt (to Bayerische Stickstoff-Werke A.-G.). U. S. 2,169,826, Aug. 15. Production of HNO_3 of 70% or higher strength is effected in a single continuous operation by oxidizing NH_3 catalytically, scpg. from the combustion gases water which is in excess of that required for the process, producing water-contg. HNO_3 and liquid NO_2 from the resulting

gases, continuously pumping such liquids, in proper proportion for producing the concd. acid, into a reaction zone maintained at a pressure above atm. pressure and sufficient for the reaction, lubricating the pump used with inorg. colloids such as silicic acid and supplying O to the reaction zone and continuously removing the highly concd. HNO_3 from the reaction zone. An arrangement of app. is described.

Apparatus for the working up of nitrous gases from ammonia combustion to nitric acid by absorption with aqueous liquid under pressure. Hydro Nitro Soc. anon. and Mieczyslaw J. Kalous. Brit. 505,620, May 10, 1939. The app. comprises a series of superposed externally cooled absorption chambers in the form of horizontally disposed tubes, the diam. of which is detd. by a ratio of cooled wall surface to enclosed chamber vol. of at least 5 sq. m. to a cu. m., and means for bubbling the gas through the liquid, which is maintained at a required depth in each tube.

Alkali metal hyposulfites. Heinrich Dehnert (to I. G. Farbenind. A.-G.). U. S. 2,172,275, Sept. 5. See Ger. 605,850 (*C. A.* **33**, 1109[3]).

Stabilized hypochlorite solution. Larry J. Barton (to Clorax Chemical Co.). U. S. 2,170,108, Aug. 22. A soln. is prepd. having a concn. of available Cl greater than that corresponding to an aq. soln. of NaOCl having a strength of 3% by wt. and which is substantially free of basic hydroxide.

Phosphate products. John W. Turrentine. U. S. 2,170,843, Aug. 29. A gas contg. NOCl is caused to react with phosphate rock in the presence of water to produce a water-sol. reaction product, which may be converted into $Ca(NO_3)_2$ by the oxidized N oxides formed. An arrangement of app. is described.

Aluminum compounds. Zwittelstocks-A.-G., Paul A. F. Baumert and Ernst Schiebold. Brit. 506,734, May 26, 1939. Products suitable for the production of other Al compds. are obtained by melting and then cooling a mixt. of materials comprising Al_2O_3, SiO_2, alk. earth compds. and, if desired, F compds., the product having a compn. $1CaO.xSiO_2.yAl_2O_3.zAlF_3$, wherein x is 1 or above, y is preferably 0.2 and z is preferably 0.2, provided that y and z are not both equal to zero. The F may be replaced in part by OH, and the Ca wholly or partly by Ba or Mg. The melt may be cooled by being quenched in H_2O or mineral acid, e. g., H_2SO_4, in which it dissolves. Waste industrial H_2SO_4, HNO_3 or HCl contg. a small quantity of the corresponding salts may be used. Charge materials naturally contg. F, e. g., topaz, topaz gangs, may be used, or F-contg. material, e. g., CaF_2, AlF_3, may be added, whereby the fusion temp. is substantially reduced, e. g., to 1300° or less. Suitable alk. earth charge materials are CaO, limestone, gypsum or anhydrite. When the latter are used, the SO_3 evolved is collected in H_2O, the acid formed being used for soln. of the product.

Soluble silicate compositions. Dolové a Prumyslové Závody Dříve Jan Dav. Starck. Brit. 507,396, June 14, 1939. In compns. contg. a sol. silicate and a powd. inorg. substance, e. g., PbO, Al_2O_3, Al silicate, feldspar, SiC, quartz, alk. earth metal compds. such as sulfates, the inorg. substance is treated, to etch the surfaces, with HF with or without other acids, e. g., H_2SO_4, H_3BO_3, prior to being mixed with the silicate soln.

Calcining calcium carbonate for lime production. Ray C. Newhouse (to Allis-Chalmers Mfg. Co.). U. S. 2,171,507, Aug. 29. The raw material is introduced into the feed end of a rotating kiln provided with an enlarged calcining zone adjacent its discharge end where the material is exposed to a flame, and is transferred from the calcining zone to a zone of lower temp.

Chlorine dioxide. Geo. L. Cunningham (to Mathieson Alkali Works). U. S. 2,172,434, Sept. 12. An aq. soln. contg. manganous chlorate is heated to 50–90° while the formed ClO_2 is continuously removed by passing a stream of inert gas through the reaction soln.

Dissolving ferric sulfate. John F. White (to Monsanto Chemical Co.). U. S. 2,172,312, Sept. 5. For prepg. a diff. sol. of $Fe_2(SO_4)_3$, pellets of anhyd. $Fe_2(SO_4)_3$ formed by calcining hydrated ferric sulfate are mixed with water of ordinary atm. temp. in an amount 1–3 times that of the sulfate and the mixt. is agitated to form a concd. soln., which is then added to water to effect the desired diln.

Mixture containing dried magnesium hydroxide, etc. Bruce Walton (to Chas. H. Phillips Chemical Co.). U. S. 2,169,983, Aug. 15. A dried mixt. capable of forming a stable suspension on being mixed with water contains finely divided $Mg(OH)_2$, sugar, Mg citrate and Na citrate.

Oxygen-generating compositions. Moses L. Heim and Karl Fiedler (Fiedler to Moses L. Heim). U. S. 2,170,052, Aug. 22. A compn. for producing O baths comprises an alkali metal percompd., such as Na perborate or percarbonate readily giving up O on contact with water, and Na lignin sulfonate in sufficient amt. (which may be about 20%) to stabilize the percompd. in dry storage and to accelerate evolution of O from it in water.

Beryllium. Helmut von Zeppelin (to I. G. Farbenind. A.-G.). U. S. 2,171,439, Aug. 29. An intimate solid mixt. of $BeCl_2$ and Mg is heated to a reacting temp. by heat transmitted from a medium which is inert to Be, and the Be is sepd. from the saline residue. Cf. *C. A.* **33**, 5797[6].

Separation of magnesium from beryllium. Helmut von Zeppelin (to I. G. Farbenind. A.-G.). U. S. 2,170,394, Aug. 22. For removing Mg from a mixt. of Be and Mg, the mixt. is treated with an aq. soln. contg. at least about twice the theoretical amt. of one or more of the compds. NH_4Cl, $(NH_4)_2SO_4$, NH_4NO_3 or NH_4OAc (suitably in a 10% soln.).

Calcining gypsum. John G. Brush (to American Cyanamid & Chemical Corp.). U. S. 2,170,745, Aug. 22. App. is described, and a method which involves continuously feeding the material in a stream through a flame at greater than a calcining temp.

Reducing kieserite. Hans Zirngibl and Robert Griessbach (to I. G. Farbenind. A.-G.). U. S. 2,171,966, Sept. 5. A process for reducing kieserite, with formation of MgO and a single reduction product of the SO_3 radical in one stage, comprises bringing the kieserite, in the presence of a catalyst of the group consisting of oxides and sulfides of Fe, Cu, Mo and W, into contact with H or H_2S, heated to about 700° and kept in circulation, at least 10 times the theoretically necessary quantity of reacting gas being brought into contact with each quantity of kieserite.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

The significance of radiation chemistry and its procedures for the science and technology of glass. H. Freytag. *Glastech. Ber.* **17**, 240–7(1939). J. F. H.

Method of making visible the temperature distribution in glass furnaces. F. Drexler and W. Schutz. *Glastech. Ber.* **17**, 205–7(1939).—A series of colored powders called "Thermo-color" was developed by I. G. Farbenind. A. G., which has the property of changing color at definite temps. By applying to a heated refractory surface the various temp. zones become visible. They should be useful in studying temp. distribution in molds and as warnings against overheating. J. F. Hyde

Use of the electric metal spray gun in glass technology. M. U. Schoop. *Glastech. Ber.* **17**, 217–18(1939).—A small arc fuses the metal which is then atomized by compressed air. Glass wool was also made by use of a Schoop gun. Enamels, glass and quartz coatings have also been made successfully with an acetylene flame. J. F. Hyde

Molecular refraction in glasses. W. Geffcken. *Glastech. Ber.* **17**, 237–40(1939).—The additivity of const.

scribed, and a mode of operation for prepg. spherical, spheroidal, ovoidal and similarly shaped articles for pharmaceutical and other purposes, and comprising a colloidal matrix having dispersed therein a vitamin-bearing liquid completely enveloped and imprisoned by the colloidal matrix so that there is no free vitamin-bearing liquid on the surface of the product. Gelatin compns. mixed with vitamin C may be used.

Vaccines, etc. Chemische Fabrik vorm. Sandoz. Brit. 506,095, May 23, 1939. Material for inoculation purposes is prepd. by freeing cultures of bacteria, etc., from H_2O by exposure to a high vacuum at below 0° and killing the bacteria, etc., in the moisture-free state by treatment with anhyd. cell poisons or radiations of short wave lengths. Among examples, *Staphylococci* are, after being frozen and dried, killed by a soln. of HCN in C_6H_6.

Antitoxins against bacterial toxins, from the liver and spleen. Carl L. Lautenschläger and Willy Ludwig (to Winthrop Chemical Co.). U. S. 2,171,320, Aug. 29. Slightly acid autolyzed spleen or autolyzed liver is extd. with water or a water-sol. org. solvent of low mol. wt. such as MeOH or with an aq. mixt. of such an org. solvent, and the soln. thus formed is treated with a "ballast-eliminating" heavy-metal compd. such as Fe dialysate and the resulting product is further purified by use of a water-sol. org. solvent such as MeOH (all steps of the process being carried out at a temp. below about 40°).

Antipoliomyelitis serum. John A. Toomey (to Western Reserve University). Brit. 507,376, June 14, 1939. The serum is obtained by immunizing an animal by successive injections of poliomyelitis virus fortified with products of metabolism of intestinal bacteria and obtaining a serum from the blood of the animal. A soln. of the virus in normal saline with which the fortifying material is to be admixed may be obtained by adsorbing the virus on $Al(OH)_3$ gel and eluting the adsorbed virus.

Disinfectant and cleansing compositions. Günther Parizot. Brit. 506,451, May 30, 1939. Tablets for use in cleansing and disinfecting artificial dentures placed in H_2O are made by compressing a mixt. of Na_2O_2 about 2 and NaCl about 3 parts. A substance, e. g., Na phosphate, for pptg. hardening agents from hard H_2O may be added to the mixt. Other agents that do not decomp. Na_2O_2, e. g., Na_2CO_3, calcined soda, may be present.

Absorbent wadding suitable for surgical purposes. Hans Freudenberg (to Carl Freudenberg G. m. b. H.). U. S. 2,169,947, Aug. 15. Wadding consisting of absorbent collagenous fibers substantially free from water is formed of fibers produced by converting animal hide material into a swollen condition in which the fibers may be mechanically isolated, shredding and treating the resulting coarse fibrous material with water-miscible org. liquids such as alc. or acetone, and further finely shredding.

Perfumes containing ketals, etc. Albert Weissenborn (to Winthrop Chemical Co.). U. S. 2,169,984, Aug. 15. Various perfume mixts. are described, which have an odor similar to geranium oil, rose, jasmine or honey, and which contain ketals having 6 to 9 C atoms in the ketone residue, such as diisopropylpyrocatechol ketal, methylamylpyrocatechol ketal or diisobutylpyrocatechol ketal, in mixt. with various other compds.

Water-soluble capsules for cosmetic purposes. Karl W. Schmidt. U. S. 2,170,253, Aug. 22. Capsules for holding volatile products such as perfumes for use in bath water are made by forming urea into the shape of a capsule and then subjecting it to a pressure of at least 1000 kg. per sq. cm. to render the urea impervious to passage of the volatile products without destroying the soly. of the capsule in water.

Massage creams. Ida G. Blish. U. S. 2,172,118, Sept. 5. A high mol. wt. fatty acid such as stearic or palmitic acid is used with a soap such as the Na soap of a high-mol. fatty acid, together with a wax such as beeswax and ceresin, and sufficient readily volatile alc., etc., to produce a cream which is substantially fluent at body temps., and with a small proportion of a low-mol. fruit acid such as citric acid or HOAc to produce a surface film during use which rolls off the surface in the form of filaments.

Detergents in cake form for toilet purposes. Wm. G. Beckers. U. S. 2,169,829, Aug. 15. A mildly acid detergent of good lathering and cleansing properties is formed of boric acid (which serves as a binder) and the Na salt of the acid sulfuric acid ester of tech. lauryl alc. or other suitable water-sol. salt contg. an alkyl radical of at least 8 C atoms and radicals of sulfuric or phosphoric acid.

Bleaching tobacco. Hermann Baier (to Deutsche Gold- und Silber-Scheideanstalt vorm. Roessler). U. S. 2,170,107, Aug. 22. Tobacco is first moistened with a soln. of H_2O_2 and is subsequently subjected to the action of a reducing agent such as glucose and tobacco sauce which reduces and destroys residual H_2O_2. Cf. *C. A.* **33**, 3974[4].

Cigaret paper. Paul Poetschke. U. S. 2,171,986, Sept. 5. The paper carries sufficient NH_4NO_3, urea nitrate, hexamethylenetetramine or a water-sol. amino acid that the burning paper yields an alk. smoke.

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

E. M. SYMMES

Borax—its manufacture and uses. E. M. Kitchen. *Am. Fertilizer* **91**, No. 7, 7–9, 24, 26(1939).—A review of the processes used in the manuf. of borax in the U. S., of the uses to which it is put in many industrial processes, of its value in promoting the healthy growth of crops on B-deficient soils and of methods of applying it to the soil.

W. H. Ross

Bores for brine in Sarjapur nala, Raichur district. L. S. Krishnamurthy and H. S. Krishnamurthy. *J. Hyderabad Geol. Survey* **3**, Pt. 2, 1–23(1938).; cf. *C. A.* **32**, 2468[4].—Details of 22 bores averaging 20–30 ft., along the bed of the Sarjapur nala, are given, with analyses of the brine obtained therefrom. The av. content in lb./1000 gal., was NaCl 13, Na_2SO_4 3.76, $MgCl_2$ 0.52, $MgSO_4$ 6.67, $CaCO_3$ 1.02 and $CaSO_4$ 3.53. The economic possibilities are discussed.

C. A. Silberrad

The industrial extraction of krypton and xenon from the air, and a historical review of the industry engaged in the production of liquid air. George Claude. *Ice and Cold Storage* **42**, No. 497, 118(1939).—The extn. of Kr from air by washing the cooled air with liquid air is discussed.

A. H. Johnson

Recovery of heat from the gases from roasting pyrite and burning sulfur. Rudolf Pitz. *Arch. Wärmewirt.* **20**, 107–9(1939). Heat-balance calcns. are presented to show the possibilities of heat recovery for these processes.

Ernest W. Thiele

Concentration of sulfuric acid. Willi Büsching. U. S. 2,172,058, Sept. 5. App. is described, and a process involving concg. the acid to about 94%, passing this acid through a wide introduction pipe into a closed vessel and introducing the acid at the bottom of the vessel, maintaining a substantial body of acid in the vessel surrounding the pipe and in heat-exchange relation with the acid in the pipe, heating the acid in the vessel, concg. the acid mainly in said pipe by regulating the heating and rate of introduction of the acid so that the acid leaving the introduction pipe is concd. to about 98%, withdrawing acid from the vessel and withdrawing vapors from the heated acid through the introduction pipe.

Concentrated nitric acid. Rudolf Wendlandt (to Bayerische Stickstoff-Werke A.-G.). U. S. 2,169,826, Aug. 15. Production of HNO_3 of 70% or higher strength is effected in a single continuous operation by oxidizing NH_3 catalytically, sepg. from the combustion gases water which is in excess of that required for the process, producing water-contg. HNO_3 and liquid NO_2 from the resulting

gases, continuously pumping such liquids, in proper proportion for producing the concd. acid, into a reaction zone maintained at a pressure above atm. pressure and sufficient for the reaction, lubricating the pump used with inorg. colloids such as silicic acid and supplying O to the reaction zone and continuously removing the highly concd. HNO_3 from the reaction zone. An arrangement of app. is described.

Apparatus for the working up of nitrous gases from ammonia combustion to nitric acid by absorption with aqueous liquid under pressure. Hydro Nitro Soc. anon. and Mieczyslaw J. Kalous. Brit. 505,620, May 10, 1939. The app. comprises a series of superposed externally cooled absorption chambers in the form of horizontally disposed tubes, the diam. of which is detd. by a ratio of cooled wall surface to enclosed chamber vol. of at least 5 sq. m. to a cu. m., and means for bubbling the gas through the liquid, which is maintained at a required depth in each tube.

Alkali metal hyposulfites. Heinrich Dehnert (to I. G. Farbenind. A.-G.). U. S. 2,172,275, Sept. 5. See Ger. 665,850 (*C. A.* **33**, 1109[3]).

Stabilized hypochlorite solution. Larry J. Barton (to Clorax Chemical Co.). U. S. 2,170,108, Aug. 22. A soln. is prepd. having a concn. of available Cl greater than that corresponding to an aq. soln. of NaOCl having a strength of 3% by wt. and which is substantially free of basic hydroxide.

Phosphate products. John W. Turrentine. U. S. 2,170,843, Aug. 29. A gas contg. NOCl is caused to react with phosphate rock in the presence of water to produce a water-sol. reaction product, which may be converted into $Ca(NO_3)_2$ by the oxidized N oxides formed. An arrangement of app. is described.

Aluminum compounds. Zwittelstocks-A.-G., Paul A. F. Baumert and Ernst Schiebold. Brit. 506,734, May 26, 1939. Products suitable for the production of other Al compds. are obtained by melting and then cooling a mixt. of materials comprising Al_2O_3, SiO_2, alk. earth compds. and, if desired, F compds., the product having a compn. $1CaO.xSiO_2.yAl_2O_3.zAlF_3$, wherein x is 1 or above, y is preferably 0.2 and z is preferably 0.2, provided that y and z are not both equal to zero. The F may be replaced in part by OH, and the Ca wholly or partly by Ba or Mg. The melt may be cooled by being quenched in H_2O or mineral acid, e. g., H_2SO_4, in which it dissolves. Waste industrial H_2SO_4, HNO_3 or HCl contg. a small quantity of the corresponding salts may be used. Charge materials naturally contg. F, e. g., topaz, topaz gangs, may be used, or F-contg. material, e. g., CaF_2, AlF_3, may be added, whereby the fusion temp. is substantially reduced, e. g., to 1300° or less. Suitable alk. earth charge materials are CaO, limestone, gypsum or anhydrite. When the latter are used, the SO_3 evolved is collected in H_2O, the acid formed being used for soln. of the product.

Soluble silicate compositions. Dolové a Prumyslové Závody Dříve Jan Dav. Starck. Brit. 507,396, June 14, 1939. In compns. contg. a sol. silicate and a powd. inorg. substance, e. g., PbO, Al_2O_3, Al silicate, feldspar, SiC, quartz, alk. earth metal compds. such as sulfates, the inorg. substance is treated, to etch the surfaces, with HF with or without other acids, e. g., H_2SO_4, H_3BO_3, prior to being mixed with the silicate soln.

Calcining calcium carbonate for lime production. Ray C. Newhouse (to Allis-Chalmers Mfg. Co.). U. S. 2,171,507, Aug. 29. The raw material is introduced into the feed end of a rotating kiln provided with an enlarged calcining zone adjacent its discharge end where the material is exposed to a flame, and is transferred from the calcining zone to a zone of lower temp.

Chlorine dioxide. Geo. L. Cunningham (to Mathieson Alkali Works). U. S. 2,172,434, Sept. 12. An aq. soln. contg. manganous chlorate is heated to 50–90° while the formed ClO_2 is continuously removed by passing a stream of inert gas through the reaction soln.

Dissolving ferric sulfate. John F. White (to Monsanto Chemical Co.). U. S. 2,172,312, Sept. 5. For prepg. a dil. soln. of $Fe_2(SO_4)_3$, pellets of anhyd. $Fe_2(SO_4)_3$ formed by calcining hydrated ferric sulfate are mixed with water of ordinary atm. temp. in an amount 1–3 times that of the sulfate and the mixt. is agitated to form a concd. soln., which is then added to water to effect the desired diln.

Mixture containing dried magnesium hydroxide, etc. Bruce Walton (to Chas. H. Phillips Chemical Co.). U. S. 2,169,983, Aug. 15. A dried mixt. capable of forming a stable suspension on being mixed with water contains finely divided $Mg(OH)_2$, sugar, Mg citrate and Na citrate.

Oxygen-generating compositions. Moses L. Heim and Karl Fiedler (Fiedler to Moses L. Heim). U. S. 2,170,052, Aug. 22. A compn. for producing O baths comprises an alkali metal percompd., such as Na perborate or percarbonate readily giving up O on contact with water, and Na lignin sulfonate in sufficient amt. (which may be about 20%) to stabilize the percompd. in dry storage and to accelerate evolution of O from it in water.

Beryllium. Helmut von Zeppelin (to I. G. Farbenind. A.-G.). U. S. 2,171,439, Aug. 29. An intimate solid mixt. of $BeCl_2$ and Mg is heated to a reacting temp. by heat transmitted from a medium which is inert to Be, and the Be is sepd. from the saline residue. Cf. *C. A.* **33**, 5797[6].

Separation of magnesium from beryllium. Helmut von Zeppelin (to I. G. Farbenind. A.-G.). U. S. 2,170,394, Aug. 22. For removing Mg from a mixt. of Be and Mg, the mixt. is treated with an aq. soln. contg. at least about twice the theoretical amt. of one or more of the compds. NH_4Cl, $(NH_4)_2SO_4$, NH_4NO_3 or NH_4OAc (suitably in a 10% soln.).

Calcining gypsum. John G. Brush (to American Cyanamid & Chemical Corp.). U. S. 2,170,745, Aug. 22. App. is described, and a method which involves continuously feeding the material in a stream through a flame at greater than a calcining temp.

Reducing kieserite. Hans Zirngibl and Robert Griessbach (to I. G. Farbenind. A.-G.). U. S. 2,171,966, Sept. 5. A process for reducing kieserite, with formation of MgO and a single reduction product of the SO_3 radical in one stage, comprises bringing the kieserite, in the presence of a catalyst of the group consisting of oxides and sulfides of Fe, Cu, Mo and W, into contact with H or H_2S, heated to about 700° and kept in circulation, at least 10 times the theoretically necessary quantity of reacting gas being brought into contact with each quantity of kieserite.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

The significance of radiation chemistry and its procedures for the science and technology of glass. H. Freytag. *Glastech. Ber.* **17**, 240–7(1939). J. F. H.

Method of making visible the temperature distribution in glass furnaces. F. Drexler and W. Schutz. *Glastech. Ber.* **17**, 205–7(1939).—A series of colored powders called "Thermo-color" was developed by I. G. Farbenind. A. G., which has the property of changing color at definite temps. By applying to a heated refractory surface the various temp. zones become visible. They should be useful in studying temp. distribution in molds and as warnings against overheating. J. F. Hyde

Use of the electric metal spray gun in glass technology. M. U. Schoop. *Glastech. Ber.* **17**, 217–18(1939).—A small arc fuses the metal which is then atomized by compressed air. Glass wool was also made by use of a Schoop gun. Enamels, glass and quartz coatings have also been made successfully with an acetylene flame. J. F. Hyde

Molecular refraction in glasses. W. Geffcken. *Glastech. Ber.* **17**, 237–40(1939).—The additivity of const.

refraction increments as developed by Biltz and coworkers (cf. *C. A.* **33**, 5140[3]) is of practical use in the field of technically important glasses, but the dependence of the increments on concentration as emphasized by Kordes must be considered in presenting total refraction curves. Biltz and coworkers failed properly to consider the work of Wulff and Majumdar (*C. A.* **30**, 3695[3]) on B_2O_3-N_2O glasses where definite departure from additivity was shown. The similarity in behavior of aq. solns. and glasses is strongly emphasized. G. prefers the use of partial molal quantities in presenting such data compared to the methods of Biltz or Kordes. An example of the use of partial molal quantities is given in detail; the data of Wulff and Majumdar are used for the system B_2O_3 Na_2O.

J. F. Hyde

Quantitative spectral analysis of boric oxide in glass. I. Kenzo Harai. *J. Chem. Soc. Japan* **60**, 668–74(1939). The powd. sample of glass is placed in a Cu electrode. A direct arc is made and the arc is studied spectrographically. It is found that log ($[B_2O_3]/[SiO_2]$) and log ($[B_2O_3/[SiO_2]$) lie roughly in a straight line, where $[B_2O_3]$ is the quantity of B_2O_3 in the glass, and IB_2O_3 is the intensity of spectral line. T. Katsurai

Notes on the chemical analysis of clays. W. Keyser and E. Pahlavouni. *Verre silicates ind.* **10**, 277–80, 293–7 (1939). The method adopted by the A. S. T. M. in 1936 was investigated and the following changes were made: the sample is fused with NaOH in a Ni crucible at about 450°; the nonvolatile residue after attack of the SiO_2 by HF is united with the filtrate from the SiO_2 before pptg. R_2O_3; the double pptn. by NH_3 is used in the presence of a large excess of NH_4Cl; the SiO_2 found in the R_2O_3 is disregarded; the TiO_2 is dctd. colorimetrically and the Fe by permanganic oxidation of the Fe previously reduced by nascent H. Herbert S. Willson

Improvement of clays through pH control. Geo. J. Barker and Emil Truog. *Brit. Clayworker* **48**, 233–6 (1939); cf. *C. A.* **33**, 8372[2].—Many clays can be greatly improved by the adjustment of their pH. Clays which are naturally acid should be adjusted to the range of 6–8.5 pH and nonacid clays fall within the range of 7.3–10.5. Na_2CO_3 is recommended for pH adjustment. The optimum pH may be dctd. as follows: To a series of 20-g samples add 50 cc. of distd. H_2O and varying amts. of Na_2CO_3. The range varies from 0.1 to 1.0% of the dry clay. After stirring occasionally dct. the pH and plot the resulting values. At a certain stage this curve usually flattens out rapidly. The pH at this point is the best. When the base-exchange material is largely satd. with Ca and Mg it tends to flocculate. Satn. partially or wholly with Na greatly facilitates deflocculation. In acid clays, the base-exchange material is usually satd. with varying proportions of H, Ca and Mg and the pH is always below 7. When Na_2CO_3 is added, H is first displaced and the pH rises. When it reaches the range 6–8.5, a sufficient amt. of Na has entered the exchange material to bring about the desired deflocculation. With nonacid clays the base-exchange material is almost completely satd. with Ca and Mg and the pH value is above 7. To displace a sufficient amt. of these cations with Na to promote the desired deflocculation it is necessary to raise the pH still higher through the addn. of Na_2CO_3. In the reaction that follows, the displaced Ca and Mg are pptd. as insol. and therefore inactive carbonates. E. V. P.

Occurrence of sillimanite in Travancore, its importance and uses. S. Dogar Singh. *Govt. Cegam. Ceneerns, Kundara, Travancore, India, Bull.* **1938**, 6 pp.—Sillimanite occurs in grain form along with ilmenite, garnet, monazite and zircon in the beach sands and can be easily sepd. by mech. means. It is also obtainable as a by-product in the washing of china clay. S. develops a theory that when "quartzitic porcelain" is subjected to sudden and repeated temp. changes the amorphous matrix caused by the fusion of silicate does not allow the quartz crystals to expand or contract uniformly in all directions; hence the crystal tends to develop cracks along cleavage planes. This is one cause of breakage of lab. porcelain. Sillimanite crystals resist the attack of feldspar much better than do the crystals of quartz in the early stages of firing. As the temp. rises, they are dissolved. But unlike quartz crystals no allotropic modifications come into existence followed by partial crystn. for sillimanite becomes monotropic after firing. Sillimanitic porcelain is less translucent than quartzitic porcelain because sillimanite crystals are not porous and cell-like. Finely ground sillimanite particles behave exactly like clay particles in their behavior toward electrolytes. Uniform and thinner wares can be produced by using sillimanite. A. P. Som

Progress in the field of refractories in 1938. C. R. Platzmann. *Tonind.-Ztg.* **63**, 256–7, 266–8, 310–11, 348–50, 395–6(1939).—A review. A. E. Beitlich

The evaluation of chrome ores for the manufacture of refractories. Th. Schauer. *Tonind.-Ztg.* **63**, 701–2, 724–5 (1939). Studies of the chem. and mineralogical compn. of various types led to the conclusion that values of [% MgO − (% Al_2O_3 ÷ 2.67)] ÷ % SiO_2 between 1.38 and 5 indicates an ore of good quality for the manuf. of refractories. For chrome-magnesite brick, the ore may contain more SiO_2 (up to 18%) without resulting in the formation of $2FeO.SiO_2$ or free SiO_2. A. E. Beitlich

Refractories in induction furnaces. Bertil Stalhane and Valter Anderson. *Jernkontorets Ann.* **123**, 386–412 (1939). The refractory should have chem. properties approaching those of MgO, which is not affected by the melt and is resistant to CaO-FeO slag. Shrinkage should be minimized by pre-stamping or hydraulic ramming, by a careful choice of grain sizes and by use of homogenizing agents. The thermal expansion around 1300° should be low to avoid formation of cracks. For temps. up to 1900° it is desirable to introduce a slight plasticity; ZrO_2 appears to be a desirable modifying agent. A new refractory, called the *BM mass*, has been developed. H. C. Duus

Refractories for open hearths. Everett C. Hite and Gilbert Soler. *Brick & Clay Record* **95**, No. 2, 54–7; No. 3, 59–60; No. 4, 54–5(1939).—A review and general discussion. Bibliography. E. C. Petrie

Brick linings for rotary furnaces. C. C. Downie. *Mining Mag.* **61**, 137–9(1939).—The adoption of the rotary furnace in England for the smelting of ores and residues has been slow, but its advantages are now being recognized. There is no slag-line as in a reverberatory hearth and the refractories wear away uniformly but slowly. A. W. Furbank

Preparation of crucibles from special refractories by slip-casting. John G. Thompson and Manley W. Mallett. *J. Research Natl. Bur. Standards* **23**, 319–27(1939) (Research Paper No. 1236).—Thin-walled (3 mm.) crucibles of Al_2O_3, BeO, zircon or ZrO_2 and electrically fused ThO_2 were successfully made from aq. slips. Enough plasticity for casting was developed by fine-grinding and treatment with dil. HCl. Most MgO crucibles cast from aq. slips cracked badly during drying and firing. When the MgO was suspended in abs. alc. good crucibles were obtained. Slips with 95% alc. did not produce good results. A. W. King

Refractory and acid-resistant mortars. Reinhart *Tonind.-Ztg.* **63**, 617–19(1939).—A patent review and description of various types: SiO_2 mortars, high-Al_2O_3 cement, magnesite, olivine mortar, chromite and others. A. E. Beithch

Salt glazing in production. Eugene C. Clemens. *Brit. Clayworker* **48**, 226–9(1939).—The NaCl in the presence of heat and H_2O vapor decomps. to form Na_2O and HCl which exerts a fluxing action to form Na-Al silicate glass. The chief requirement of a clay body for glazing is a wide range of chem. compn. to permit a glaze to be formed from the hottest to the coolest portions of the kiln. SiO_2 should be about 65%. Minerals such as gypsum, limestone, dolomite and marl, contg. Ca or Mg, may cause trouble in glazing; finer grinding will distribute them and reduce their chem. activity. Temp. control is essential as sudden increases may cause surface overfiring and sudden decreases may cause "off" color areas in the kiln. Rapid cooling has a tendency to produce brilliant glazes while slow cooling will produce darker and nearly matt glazes. Finely ground bodies take a glaze more rapidly

and with more uniformity of color than coarsely ground clay. Fuels used for firing the kilns should be low in S. The chlorides of Zn and Mn may be mixed with NaCl to produce a darker shade of red. E. C. Petrie

Electromagnetic method of determining enamel thickness. K. Azarov and N. Kharchenkova. *Zavodskaya Lab.* **8**, 508-12(1939).—The method is based on changes in magnetic resistance of a closed circuit contg. an electromagnet and the enameled specimen. The thickness of the layer is estd. by current changes in the coil of the electromagnet. The measurements are made regardless of the thickness of the Fe sheet. The disadvantage of the method (a Cu oxide rectifier is used) is the effect of the outside temp. The app. may be used for lab. control work but corrections should be made for the surrounding temp. Diagram of the set-up and results of tests are given. B. Z. Kanich

Use of Na-Mg glass for glass electrodes (Pasynskii) 4. Firing furnaces for melting glass with natural gas (U. S. pat. 2,171,597) 21.

Glass-melting furnaces. The British Thomson-Houston Co. Ltd. Brit. 506,366, May 26, 1939.

Electric furnaces for heating glass. Soc. anon. des manufactures des glaces et produits chimiques de St.-Gobain, Chauny et Cirey. Brit. 506,696, June 2, 1939. In heating liquid glass by current between electrodes, 1 or more bodies of high cond. are arranged in the glass between the electrodes to produce zones of heat concn.

Apparatus for feeding mold charges of molten glass. Thomas F. Pearson (to Crown Cork & Seal Co.). U. S. 2,171,096, Aug. 29. Various structural, mech. and operative details.

Machines of the suction-gathering type for making hollow glassware. Kent-Owens Machine Co. Brit. 505,965, May 15, 1939. Divided on 503,921 (*C. A.* **33**, 7510[2]).

Automatic machines for making glass bottles. Henry C. Daubenspeck and Thomas B. Kitson. Brit. 506,499, May 30, 1939.

Method of making hollow glass articles, e. g., building blocks. Raymond W. Kell (to Corning Glass Works). Brit. 507,387, June 14, 1939. In making articles from preformed parts by heating the edges of the parts and fusing them together, the heating of the engaging parts is effected by substantially endless gas flames, and the direction and flow of the flames over the engaging parts are controlled by removing the burnt gases from the neighborhood of the flames.

Glass building blocks. John E. Bauer (to Owens-Ill. Glass Co.). U. S. 2,170,602, Aug. 22. App. is described, and a method which consists in producing a hollow glass building block having mortar-bearing surfaces and prior to any great loss of heat from the block applying to such surfaces in a molten state a substantially uniform film of metal such as Al or an Al alloy having an affinity for glass, dispersing a gritty material such as sand over the film of metal while the latter is still plastic and capable of adhesion, and annealing the block.

Glass container. Joseph Szanto. Brit. 505,744, May 16, 1939. In the manuf. of containers by the drawing of tubes, means are provided to insure relative movement between the burner and the tube.

Glass fibers. Vetrocoke (formerly Vetrocoke, Società riunite italiane (vetri e cristalli e italiana coke) anon.). Brit. 505,934, May 19, 1939. In the manuf. of the fibers, the molten material flows through electrically heated orifices, 1 or more of which can be plugged at will, past a cooling device and burners onto a rotary member adjustably mounted on a movable carriage. Cf. *C. A.* **33**, 2667[5].

Coating glass surfaces. The British Thomson-Houston Co. Ltd. Brit. 507,187, June 12, 1939. In an app. for coating a vitreous tube with enamel, the tube with a layer of enameling mixt. applied to its inner surface is mounted around an elec. heating element. The tube is rotated during the heating by rollers and means are provided for introducing gases into the tube. The inner surface may first be etched and a soln. of Na borate or a mixt. of B_2O_3 3, SeO_2 2 and $NaNO_3$ 0.125 mol. parts applied to the surface by the heating process.

Optical glass. Geo. W. Morey (to Eastman Kodak Co.). U. S. reissue 21,175, Aug. 15. A reissue of original patent No. 2,150,694 (*C. A.* **33**, 4754[5]).

Tempering glass. Corning Glass Works. Brit. 505,626, May 11, 1939. A chilling-medium, for use in tempering glass, consists of a molten liquid composed substantially of $Ca(NO_3)_2$, $Ba(NO_3)_2$, $Sr(NO_3)_2$ or (and) $Pb(NO_3)_2$, together with the nitrate of 1 or more alkali metals.

Tempering glass. Corning Glass Works. Brit. 505,627, May 11, 1939. In a method wherein the glass is heated or chilled by immersion in a bath of molten inorg. salt, the heating bath contains a substantial proportion of K_2CrO_4 or (and) Na_2CrO_4 and the chilling bath consists mainly of $K_2Cr_2O_7$ or (and) $Na_2Cr_2O_7$.

Tempering glass. Gilt Edge Safety Glass Ltd., August W. Grotefeld and Jesse J. Shaw. Brit. 506,724, May 26, 1939. The glass is supported while being heated by a device that engages and supports it without deformation, the temp. or condition of each piece of glass being observed and the heating being controlled accordingly.

Tempering glass. Corning Glass Works. Brit. 507,170, June 12, 1939. A chilling bath consists of 1,2,4-trichlorobenzene, diphenyl oxide or lightly chlorinated resin, e. g., a Ph_2 resin known as "Aroclor," or a mixt. of 2 or more of these or of any liquid for which at 20° log (H × 10^6) is 2.56-4.0, where H is K^3P^2BC/U, K being the thermal cond., P the sp. gr., B the coeff. of cubic expansion, C the sp. heat and U the viscosity.

Tempering glass sheets. Pilkington Brothers Ltd. Brit. 505,849, May 17, 1939. To indicate the attainment of the necessary temp. of the sheets, a pair of points are pressed against the sheet and when they have sufficiently penetrated it as a result of its plasticity elec. contact is established to give an alarm.

Tempered glass sheets. Edoardo Ferlito. Brit. 505,857, May 18, 1939. A tempered glass sheet that can be sepd. into 2 or more sections without fracture is produced by forming on 1 or both sides of the sheet, before or during the heating, 1 or more grooves along which the sheet can be divided after the tempering. Cf. *C. A.* **33**, 7510[8].

Devices for supporting glass sheets during tempering. Gilt Edge Safety Glass Ltd., Augustus W. Grotefeld and Jesse J. Shaw. Brit. 506,723, May 26, 1939, and 506,787, May 26, 1939, divided on 506,723.

Electrically heated apparatus for cutting glass sheets. Ival G. Fowler and John L. Drake (to Libbey-Owens-Ford Glass Co.). U. S. 2,169,687, Aug. 15. A device for use in cutting glass sheets includes a supporting surface for the sheet, a template above the supporting surface and an elec. resistance heater carried by the template and which may comprise a plarality of sep. heating elements arranged in end to end relation and cooperating to heat the glass sheet to a relatively high temp. along a substantially closed continuous line of cleavage.

Multi-stage furnace for heating vertical glass plates for tempering. Lewis J. Forbes (to American Securit Co.). U. S. 2,170,749, Aug. 22. Various structural, mech. and operative details.

Increasing the resistance of glass, glazes or enamels to chemical attack. Deutsche Tafelglas A.-G. (Detag). Brit. 506,124, May 23, 1939. Addn. to 454,189 (*C. A.* **31**, 1571[4]). See Ger. 678,340 (*C. A.* **33**, 7980[4]).

Machine for bending vitreous tubes or rods to a predetermined curvature. The British Thomson-Houston Co. Ltd. Brit. 507,734, June 20, 1939.

Bricks, tiles, etc. Frank Humphris. Brit. 505,652, May 16, 1939. Bricks or other materials molded from clay, etc., are produced and dried by feeding the raw material into a slightly inclined drying drum that has a tubular shell with a central conduit, chambers and baffles or shelves therein and is intermittently rotated on rollers by continuously oscillating pawls that are moved by bell-crank levers, connecting rods and a variable stroke crank-pin on a rotary driving shaft, said pawls engaging teeth

on an annular ring on the shell. The granular material is fed from a hopper to rotating angle blades on 1 end of the drum and passes by gravity to the other end, where hot gases enter, the material then passing to a grinding mill and while hot to a molding machine.

Downdraft brick, tile and other kilns. Harold Randle Holding. Brit. 506,586, May 30, 1939. In kilns wherein the bag wall is extended upward to follow more or less the contour of the roof, the extended portion is formed to provide a passage that tapers in the direction of flow of the heating-gases or, alternatively, is flared in the opposite direction.

Ceramic compositions. The British Thomson-Houston Co. Ltd. Brit. 505,830, May 17, 1939. A ceramic mix comprises TiO_2 and a preformed substantially alkali-free glass adapted to bond the TiO_2 particles into a dense mass when the mix is fired to vitrification. The material is suitable for elec. insulation purposes, e. g., in condensers. Part of the preformed glass may be replaced by nonclayey bonding components, e. g., MgO, BeO, Ca Ti silicate.

Ceramic and refractory compositions. Albert P. de Sanno, Jr. Brit. 506,879, June 6, 1939. Ceramic or refractory materials are mixed with an aq. soln. of a protective colloid, e. g., glue, casein, gelatin, soap or a sulfonated C_6H_6 or $C_{10}H_8$ deriv., then incorporated with sufficient rubber latex to serve as a temporary binder, formed into articles and fired to burn out the latex. The ceramic material may be, e. g., a mixt. of clay, flint or feldspar, and the refractory material may be sillimanite, carborundum, fused SiO_2, graphite or "Alundum" together with sufficient clay to form by fusion a permanent binder for the article. Cf. *C. A.* **33**, 7982[5].

Refractory substances. Staatliche Porzellan Manufaktur Berlin. Brit. 506,698, June 2, 1939. Materials of great hardness and elec. resistance are prepd. by mixing 85–50 parts of a pure, alkali-free, nonfused Al_2O_3 with 17–57 of pure hydrated kaolin and, if desired, a little $Al(OH)_3$ and burning the mixt. at 1700–1800° after it has been shaped to form articles such as insulators, ball mills, grinding balls, mortars, nozzles, heating-tubes, crucibles and pyrometer tubes.

Ceramic tubing. John D. Morgan and Russell E. Lowe (to Power Patents Co.). U. S. 2,171,006, Aug. 29. App. is described, and a process for the manuf. of heat-conductant electrically nonconductant tubing, involving immersing a suitably dimensioned textile cord in a bath comprising a fluid suspension of refractory material, removing the textile cord and adhering refractory coating from the bath at a controlled rate, hardening the coating by maintaining the textile cord in a heated stream of gas as it emerges from the bath, building up the coating to a suitable wall thickness and baking the textile cord and coating in an oxidizing atm. to burn out the textile cord and set the refractory forming the walls of the tubing.

Furnace linings. Giovanni Bt. Crespi. Brit. 507,715, June 20, 1939. These are made by ramming pure calcined dolomite ground to the fineness of flour and rice grains, without any addns., and heating to the working temp. of the furnace. Fe wire or rods may be incorporated as a reinforcement. For the formation of steps, gas inlets, etc., Fe molds may be used and the 1st layer to be rammed may be mixed with tar or like adhesive.

Abrasive wheels. Roland J. Goodnow and Donald B. Wilson (to Bay State Abrasive Products Co.). U. S. 2,172,243, Sept. 5. Various mfg. details.

Abrasive articles such as wheels and disks. Norman P. Robie and Walter D. Rossow (to Carborundum Co.). U. S. 2,171,635, Sept. 5. Granular abrasive material is wetted with water and the wetted material is mixed with a dry powd. condensation resin to coat the granules, and the latter are dried and heated to form them into a desired unitary structure.

Apparatus for balancing abrasive wheels during manufacture. Orello S. Buckner and Donald B. Wilson (to Bay State Abrasive Products Co.). U. S. 2,172,006, Sept. 5. Various structural, mech. and operative details.

High-temperature resistant glaze suitable for use on zircon-ferrosilicon refractories, etc. John D. Morgan (to Power Patents Co.). U. S. 2,170,387, Aug. 22. A glaze is formed by the mixing and reaction of finely ground zircon about 90–50 and H_3PO_4 about 10–50 parts, and a small proportion of finely ground ferro-Si.

Enamel composition suitable for use on metal surfaces. Robert T. Hucks (to E. I. du Pont de Nemours & Co.). U. S. 2,170,658, Aug. 22. A protective and decorative coating compn. comprises a polyhydric alc.-polybasic acid resin contg. the acid radical of an oil having drying properties such as perilla oil together with a natural resin such as dammar resin, a plasticizer such as dibutyl phthalate, a pigment and H_3PO_4 about 1% or less, which serves to give good adhesion.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Progress in cement research. C. R. Platzmann. *Zement* **28**, 537–40, 553–7, 581–3, 594–6(1939).—A review. A. E. Beitlich

New developments in the burning of cement. H. Jordan. *Zement* **28**, 524–8, 540–2(1939).—A patent review. A. E. Beitlich

Affecting the initial hardening of high-alumina cements. F. Keil and F. Gille. *Zement* **28**, 195–9(1939).—Prolonging the mixing process from 2.5 to 10 min. causes marked increases in strength. The addn. of LiCl acts similarly, but the effect depends very much on the type of cement and the amt. present. A. E. Beitlich

Influence of the water-cement ratio on the strength of mortars. A. Ceresero. *Ind. ital. cemento* **1939**, No. 2, 51.—With the same qualities of cements different results in strength are obtained depending either on the sand used or the amt. of water. Tests made by C. prove that to affect comparative tests the same sand must be used, otherwise the amt. of water must be varied. A. Giannone

Industrial floors of concrete. A. J. Boase. *Ind. Eng. Chem.* **31**, 1435–6(1939).—Reply to Stratton and Hough (*C. A.* **33**, 3103[1]). Reply. R. C. Stratton and W. A. Hough. *Ibid.* 1436. C. G.

Bitumen in protecting iron and concrete. H. Boesenberg. *IIme Congr. mondial pétrole* **3**, Sect. 4, 432–34 (1937)(in German).—Bitumen can be used effectively in combating corrosion caused by aq. media. Difficulties encountered in the application of bitumen for such purposes are reviewed. A mixt. composed of 40% crushed stone of 3–5 mm. size and 60% of a mixt. composed of 70–75% natural asphalt, 10–15% bitumen and about 15% stone meal is used as a top coating to protect the iron and concrete used in the formation of road beds. E. J. Mahler

Corrosion of concrete. G. Malquori. *Ind. ital. cemento* **1939**, No. 3, 136.—Different types of corrosion of concretes, chiefly by sea water, are summarized. The chem. reactions that occur are described and studied. All the tests now used to evaluate the strength of a cement against corrosion tend to hasten the corrosion phenomenon, that is to shorten the time of the tests; therefore these tests are made in conditions quite different from those of practice. M. advises testing the strength of a cement against corrosion, in conditions as similar to those of employment as possible. A. Giannone

Use of bitumen for waterproofing foundations in construction work. A. Braeutigam. *IIme Congr. mondial pétrole* **3**, Sect. 4, 426–31(1937)(in German).—The use of bitumen as a waterproofing agent in construction work dating back to bible days is reviewed. Results obtained in railroad tunnels, subways, etc., in American and

European cities are cited. Specifications for standard German bitumen for waterproofing are mentioned. 10 references. E. J. Mahler

The German standard specifications DIN 1060 for building limes. Karl Goslich. *Tonind.-Ztg.* **63**, 561–3 (1939).—New specifications for hydraulic limes. A. E. Beitlich

---

Refractory and acid-resistant mortars (Reinhart) 19. Rubber powder [for road purposes] (Brit. pat. 506,960) 30.

Apparatus for removing rings from cement kilns. Robert E. Boehler. U. S. 2,172,119, Sept. 5. Various structural, mech. and elec. details of an app. provided with an elec. motor.

Handling powdered materials, as in treating cement with air in a silo. Niels S. Borch (to F. L. Smidth & Co.). U. S. 2,170,258, Aug. 22. Various details of app. and operation

Cement and mortar mixtures. Edward W. Scripture, Jr. (to Master Builders Co.). U. S. 2,169,980, Aug. 15 Waste sulfite liquor is added to a hydraulic cement in a proportion of about 0.5–1.5 pints of liquor per sack of cement, and serves as a plasticizing agent.

Automatic apparatus suitable for weighing water for use in concrete batches. Geo. W. Misner (to Westinghouse Air Brake Co.). U. S. 2,170,249, Aug. 22. Various structural, mech., elec. and operative details.

Sealing or solidifying water-bearing strata. N. V. de Bataafsche Petroleum Maatschappij. Brit. 506,904, June 6, 1939. A soln. of asphalt bitumen in an org. solvent or a mixt. of org. solvents completely miscible with H_2O at the temps. existing is caused to penetrate the H_2O-bearing strata. Suitable solvents are pyridine, diammes, picoline, cinnoline, quinazoline, quinoxaline, ammopyridine or a mixt. such as pyridine and ales. The H_2O-retentive capacity of the strata may be increased as by bringing it in contact with a wetting agent. Fillers, e. g., clay, lime or ground basic slag, or soaps of heavy metals, e. g., Ca oleate or sulfonate or Fe naphthenate, may be added to the bitumen to vary its consistency or its penetration may be assisted by addns. of alkali soaps, sulfonates, naphthenates, etc.

Pavement. John B. Warden (to Barber Asphalt Corp.). U. S. 2,171,153, Aug. 29. A cold compacted stabilized mixt. of earthy materials has dispersed in it without substantial coalescence a solid bituminous compn. in finely divided form and including a water-insol. substance such as clay, which is capable of taking up moisture.

Forming expansion joints in concrete pavements Georg Wieland. U. S. 2,172,042, Sept. 5. Inserts are used formed of heat-conducting material having their side walls covered with fusible material such as bitumen or paraffin, and after embedding these bodies flush with the pavement they are heated for a short time to a temp. above the m. p. of the fusible covering material (after the concrete has become hard) and the insert body is withdrawn when its covering has become fused.

Expansion joints for paving and other constructions. International Latex Processes Ltd. Brit. 506,890, June 6, 1939. The joints are formed in a space between 2 spaced members, e. g., paving slabs, by filling the space, at least partially, with an uncoagulated latex foam and allowing the foam to form a rubber sponge *in situ*. The latex may be a natural latex or a coagulable aq. dispersion of elastic material, including artificial dispersions of rubber. The foam is preferably compounded with a material, e. g., NH_4 fluosilicate, an aq. emulsion of pine tar or a multivalent metal salt, to produce delayed coagulation whereby the foam after being poured into the joint space will gell on standing. The latex compn. also contains a low-temp. accelerator so that the sponge will vulcanize under atm. conditions. Among examples, a compn. consisting of centrifuged latex, KOH soln., S paste, di-Am NH_4 di-Am dithiocarbamate emulsion, ZnO paste and NH_4 linoleate is whipped to a foam in a whipping-machine, an 8% soln. of NH_4 fluosilicate is added and the compd. poured into the joint space.

Bituminous compositions. Baugesellschaft Malchow G. m. b. H. Brit. 506,577, May 31, 1939. Homogeneous mixts. of coal tar and petroleum bitumen are formed by selecting as the bitumen component an oxidized petroleum bitumen or one distd. under a high vacuum. The tar may be a viscous tar, very rich in pitch, of a dropping point above 25° or a tar of a dropping point below 25° and a low content, i. e., less than 40%, of anthracene oil. With a tar of dropping point less than 25° the bitumen employed has a softening point, Kraemer Sarnow, of at least 54°. A proportion of bitumen distd. under normal conditions may also be incorporated. Among examples, (1) a road-dressing comprises 50% of coal tar of dropping point about 30° and 50% of an oxidized petroleum bitumen of softening point 50–60°, and (2) a binder for a bituminous concrete comprises 50% of coal tar of dropping point 40°, 20% of normally distd. petroleum bitumen of softening point 54–58° and 30% of oxidized bitumen of softening point 75–85°. The binders may be used in making mastic-like masses in conjunction with natural asphalt powder or powd. limestone, sand and other aggregates.

Bituminous compositions. Albert E. H. Dussek. Brit. 507,850, June 21, 1939. A road dressing or grouting compn. consists of rock or mastic asphalt or Trinidad or petroleum bitumen to which a mineral filler, e. g., limestone, cement, slate dust, fine sand, has been added, with which ground or broken waste rubber has been incorporated at a temp. insufficiently high for it to dissolve. Particles of rubber may be scattered over the compn. after application.

Artificial stone. Richard Barker and Harold S. Wilson. Brit. 506,897, June 6, 1939. A portland cement-aggregate mixt. is gaged with H_2O contg. an aq. emulsion of whale oil, lime or magnesia and Na salicylate, which may also contain slate dust. The aggregate may be powd. shale, slate dust, residue sand, which may be from glass sand blasting, or granite chippings and the concrete or mortar may be molded into hard nonporous, waterproof blocks, slabs, etc.

Coloring stone. Colas Products Ltd. Brit. 506,934, June 7, 1939. Mineral materials, e. g., stone chippings, large stones, are coated with a thin layer of pigment, if desired with the aid of a liquid, e. g., H_2O, oil, that is fixed on the material by an aq. dispersion of a bituminous substance, e. g., bitumen, tar, that gels or dries to an insol. film. The colored material may be used for covering roads, floors, etc., for roof and wall coverings, for covering roof paper and as an aggregate for colored concrete.

Waterproof paint. Claude V. Smith. U. S. 2,170,163, Aug. 22. A paint suitable for use on surfaces such as cement, stucco, stone or brick is formed of $CaCl_2$, "lye," portland cement and water.

Porous building materials. Pietro Miglavacca. Brit. 506,949, June 7 1939. These are made by agitating or mixing hydraulic cement and H_2O in the presence of an alc. soln. of colophony and a soln. of strong glue while air or gas is injected through holes in the bottom of the mixing vessel. Alternatively, air or gas may be injected into a mixt. of strong glue and alc. soln. of colophony while it is agitated by means of beaters or mixers and the hydraulic binder subsequently added. Sand, powd. pumice, slate or cork, $Ca(OH)_2$ and solns. of bitumen may also be added. The frothed mixt. may be cast in molds which may be lined with bricks that combine with the porous mass to produce composite bricks.

Porous building materials suitable for insulation, etc. Hans Wolf and Hans Saenger (to I. G. Farbenind. A.-G.). U. S. 2,172,076, Sept. 5. A hydraulic binding material such as portland cement is used with about 1% or less of a sulfonic acid of an aromatic compd. contg. an alkyl radical such as a butylnaphthalene sulfonic acid.

Cellular building blocks and heat-insulating walls. Carl B. Robbins (to Calveras Cement Co.). U. S. 2,172,051–2–3, Sept. 5. Various mfg. and structural details.

Roofing granules. Clarence L. Colbert (to Empire Trust Co. as trustee). U. S. 2,170,445, Aug. 22. App. is described, and a method of making roofing granules which involves reducing a raw clay or shale to finely divided condition, mixing with water to form a plastic mass, forming into thin sheets, breaking to granular form, and subjecting to a firing temp. for hardening. 1

Asbestos-cement shingles. Wm. R. Wright, Jr. (to Patent and Licensing Corp.). U. S. 2,171,155, Aug. 29. A method of making shingles or the like from a wet mixt. of hydraulic cement and asbestos fiber comprises accumulating a plurality of superposed thin plies of the cement and fiber mixt. upon a substantially cylindrical but irregular surface to form a layer wherein the ply adjacent said surface has an irregular contour complemental in form to that of the surface and the successive superposed plies exhibit said contour to an increasingly lesser extent with the outermost of said plies substantially smooth, accumulating a plurality of superposed additional plies over the outermost of said first-named plies until a sheet of the desired thickness is built up on said surface, sepg. the sheet from the surface, subdividing said sheet into elements of suitable size and compacting the elements while still wet between surfaces of compressible deformable material to prevent substantial deformation of said irregular contour during compacting. App. is described. 2 3

Apparatus for feeding and distributing sludgy material or to surfaces, e. g., for applying hydraulic cement to shingle tiles. Bakelite Ltd. Brit. 507,012, June 7, 1939.

Preserving wood. John Bryan and Norman A. Richardson. Brit. 507,785, June 21, 1939. The wood is treated with H_2O-sol. Hg and Cr compds., if desired with the aid of vacuum and (or) pressure. Other substances, especially reducing agents, e. g., nitrites, sulfites, may be present. Suitable compns. are (1) $HgCl_2$ and K_2CrO_4, (2) $HgCl_2$, $K_2Cr_2O_7$, $NaNO_2$ and NaOH, etc.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE STERN

The combustion of motor fuels. Pekka Heinanen. *Suomen Kemistilehti* **12A**, 118-21 (in German, 121) (1939). A review. S. A. Karjala 4

Divinyl sulfide in commercial acetylene—isolation, identification and removal. D. J. Kennedy and A. C. Holm. *Can. Chem. Process Inds.* **23**, 490-5 (1939).—An org. I compd. was the cause of serious difficulties in certain synthetic processes using C_2H_2 derived from CaC_2. A method for detg. org. S consisted of combustion of the gas with air in a confined space, drawing the products of combustion through a scrubber contg. Na_2O_2 soln., and detg. the S as $BaSO_4$. The apparatus is illustrated and the operation outlined. Over 80% of the org. S was condensable from C_2H_2 gas at −80°. The liquid condensate contg., besides the S-bearing component, a large amt. of water, AcH, some AcOH and probably liquid phosphine. Fractionation of this liquid at reduced temps. and pressures in an apparatus consisting essentially of a boiler fitted with an electromagnetic stirring device, 4 condensers, cooled by dry ice, which could be isolated one from the other by means of Hg valves and a no. of receivers to which the contents of the condensers could be distd. About 95% of the S material was found to be divinyl sulfide. It is probable that the S unaccounted for was divinyl sulfide and some polymerization or decompn. product thereof. The actual divinyl sulfide or other org. S compd. content depends on the temp. of the reacting carbide during the slaking process, the higher temps. giving rise to higher org. S content. The presence of divinyl sulfide appears to have no effect on the stability of C_2H_2 and is of no practical importance in illumination or welding applications. Divinyl sulfide may be removed from C_2H_2 by scrubbing with Chloramine T or H_2SO_4, or by simply passing the gas through a suitable tower filled with activated C. 6

W. H. Boynton

Oxidation of carbonaceous materials to organic acids by oxygen at elevated pressures. R. C. Smith, R. C. Tomarelli and H. C. Howard. *J. Am. Chem. Soc.* **61**, 2398-2402 (1939).—Illinois bituminous coal, graphite and other carbonaceous materials have been oxidized to simple org. acids by O under pressure in aq. alkali at 200-250°. With lower-rank materials simple org. acids were recovered. With materials of higher rank than low-temp. coke, decreasing yields of org. acids were obtained. With graphite the chief product was CO_2. The effects of temp., time, partial pressure of O, catalysts, surface and nature of the alkali on the course of the oxidation of Pittsburgh seam coal were studied. Oxalic, trimellitic, pyromellitic, prehnitic and terephthalic acids were identified. A significant fraction forms nondistillable Me esters, indicating the presence of compds. more complex than the benzenecarboxylic acids. H. W. Leafy 8

Dangerous swelling pressures in carbonization practice. G. B. Foxwell. *Gas World* **111**, No. 2879 Coking Sect., 118-23; No. 2883 Coking Sect., 129-31 (1939).—A review. P. J. Wilson, Jr.

Methods and devices designed for the study of combustion in internal-combustion engines. R. Vichnievsky. *IIme Congr. mondial pétrole* **3**, Sect. 4, 400-5 (1937) (in French).—Review. Edward J. Mahler

Tests on four-cycle Sulzer Diesel with mechanical injection using heavy unrefined oil. Sulzer Co. *IIme Congr. mondial pétrole* **3**, Sect. 4, 390-5 (1937) (in French). Tests were carried out to compare the running periods of several hundred hrs. of a 4-cycle Sulzer Diesel engine equipped with mech. injection when operating on heavy unrefined oil, light fuel oil and unrefined fuel oil. A special arrangement for heating the heavy unrefined oil under pressure has been used successfully on the engine to permit the fuel pumps and injection nozzle to operate normally. While operating on the heavy crude oil the fuel pumps, upper piston rings and cylinder jackets showed evidence of appreciable wear owing to large amts. of clay and impurities in the fuel. Exhaust valves were clean and dry; injection nozzles exhibited no traces of appreciable wear, and no coke formed on the pistons, etc. The tests prove that Diesel engines with airless injection can be operated on crude oil if precautions are taken properly to preheat the oil under pressure. An instance is cited of such operation at a pumping station using Irak crude oil. Edward J. Mahler 5

Inflammability of the atmosphere in the crankcase of Diesel engines. H. Bara. *IIme Congr. mondial pétrole* **3**, Sect. 4, 494-9 (1937) (in French).—Tests were carried out to ascertain whether or not the atm. in the crankcase of Diesel engines was inflammable under normal running conditions. It was concluded that combustion is possible in the crankcase owing to the presence of finely divided droplets of oil projected into the crankcase and mixed therein with air. Hot spots may develop in the crankcase and thereby promote combustion of the oil droplets present. E. g., a substance heated to red heat and plunged into the crankcase will cause combustion if oil vapors are present. Introduction of inert gas into the crankcase is recommended as a remedy for possible explosions in Diesel crankcases. Edward J. Mahler 7

Production of hydrocarbons by synthesis. Werner Held. *Petroleum Z.* **35**, 493-5 (1939).—H. briefly surveys the coal-hydrogenation process and the Fischer-Tropsch hydrogenation of CO. The effect of catalyst, temp. and pressure and in the case of coal, the initial state of the material are discussed. Variations in the nature of the products formed in the hydrogenation of CO under different temp. effects, pressure changes and catalysts are shown in a table. Edward J. Mahler 9

Liquefaction of coal. III. Catalytic liquefaction of coal. Sintake Kurokawa, Kazuiti Hirota, Mituzo Huziwara and N. Asaoka. *Repts. Imp. Fuel Research Inst.*,

Japan No. 39, 79 pp.(1939); cf. Bergius, *C. A.* 20, 1313.—Oxides, chlorides, iodides, bromides and sulfides of various metals were used as catalyst either singly or in combination. In general halides are better catalysts, but they damage the inside of the autoclave. The phys. and chem. properties of the products depend upon the catalyst used. F. I. Nakamura

Experiments on coking properties of coal. H. W. Jackman. *Gas J.* 228, 84–5(1939).—See *C. A.* 33, 8387[7]. P. J. Wilson, Jr.

Influence of drying and grinding of coal on the flame combustion in powdered-fuel furnaces. Karl Cleve. *Arch. Warmewirt.* 20, 181–3(1939).—Fuels high in moisture, such as brown coal, require the addn. of more preheated air to the mill. Finer powdering shortens the flame. Ernest W. Thiele

Laboratory method of determining ash in coals. E. A. Galileeva. *Zavodskaya Lab.* 8, 668–71(1939).—For coals having an ash similar in compn. to clays contg. Fe the temp. at which ash detns. are made can be varied between 800° and 1400° without affecting the result. For brown coals and shales the ash content decreases with rising temp. owing to the decompn. of sulfates but const. results are obtained at 1100–1200°. In making an ash balance in such cases it is necessary to introduce corrections by detg. sulfates in coal and in lab. ash obtained at 800°. Differences between ash detns. in oxidizing and semi-reducing media were insignificant. B. Z. Kamich

Moistening of brown coal fines with steam. Fritz Schiffner. *Arch. Warmewirt.* 20, 92(1939).—The brown coal was heated to improve ignition, and material falling through the grate was reduced, by low-pressure steam admitted over the grate. Ernest W. Thiele

Grass peat and its utilization. Kuhei Kobayasi and S. Murai. *J. Fuel Soc. Japan* 18, 739–51(in English, a69–71)(1939).—Carbonization of grass peat gave the following constituents in percentage: gas 22, coke 40, gas water 30 and tar 8, the latter gave on distn.: distillate 6 and coke 1.6. Gas analysis gave in percentage: H 36.2, CH_4 18.9, CO 13.8, C_mH_n (...), CO_2 11.2, O 0.8, N 17.2 and calorific value of 5154 cal. Hydrogenation of grass-peat tar was carried out with Fe_2O_3 as catalyst; temp. 430°, reaction time 2 hrs., initial and final pressure 50 and 45 atm., resp., and max. pressure 240 atm. The properties of oil produced are: d. 0.820, fraction below 230° 60% and the degree of liquefaction 88%. F. I. Nakamura

Better flame combustion in the furnace by means of flame turbulence. Karl Cleve. *Arch. Wärmewirt.* 20, 149–53(1939).—Greater furnace capacity can be obtained by the use of a turbine-type burner, by the constriction of the furnace cross section above the grate, and by the use of high-pressure secondary air, properly directed. These all depend on good mixing of the flame parts. A diagram is given showing air velocities in front of a three-part turbine-type burner, when the parts are used separately and together. Ernest W. Thiele

Control of the operation of producers. Paul Fuchs. *Arch. Wärmewirt.* 20, 163–5(1939).—An elementary review. Analysis of cold producer gas is not sufficient to characterize the fuel for producers; a carbonization test is recommended. Ernest W. Thiele

Increase in capacity of grate furnaces for raw brown coal. Wilhelm Otte. *Arch. Wärmewirt.* 20, 65–7(1939).—A trough-type grate is provided with a ceramic radiation surface set over the center of the grate, to provide better drying of the feed. Ernest W. Thiele

The maintenance costs of steam-boiler furnaces. E. Uhthoff. *Arch. Warmewirt.* 20, 119–23(1939).—A review of 9 plants using brown coal, divided according to firing method. Apparently these costs are highest for powd. coal. Ernest W. Thiele

Three years at Perth. A. C. Rea. *Gas World* 111, 252–6(1939); *Gas J.* 228, 127–8, 133–4, 136, 138–9.—A bed consisting of 8 Glover-West *vertical retort*, each 50 in. × 10 in. × 25 ft. long, has been erected as the first of 5 proposed new beds. The new setting is heated by a step-grate producer equipped for pressure burning. During a week's working of the bed with combustion chamber temps. of 1200–1250° and a throughput of 4.1 tons of coal per retort per day, the proportion of fuel used (run-of-retort coke) was 8.89%. *Benzene* recovered amounted to 2.36 gal. per ton of coal, an efficiency of over 70%. Along with recovery of the benzene the S in the gas is reduced from 12 down to 7 grains per 100 cu. ft. Two to three months after *gas dehydration* was started the consumers' meters began to gum up. The trouble was relieved in 75% of the cases by application of a special meter oil to the meters *in situ*.

P. J. Wilson, Jr.

Utilization of waste heat in gas-engine cooling. D. W. Reeves. *Gas* 15, No. 11, 31–2(Nov., 1939).—It is more remunerative as regards waste-heat recovery to operate gas-engine cooling jackets at 220–250°F. than at about 160°F. as usual. The uses for steam are more numerous than for hot water and it is easier to maintain a const. jacket temp. at the higher point. A typical layout is described. Addnl. heat may be recovered from the exhaust gases. It is stated that from 4 to 5 lb. of steam at 230°F. can be recovered per brake h. p. R. W. R.

The gas industry in Switzerland. W. Tobler. *Gas World* 111, 280–3(1939).—See *C. A.* 33, 6560[8].

P. J. Wilson, Jr.

Experiments on gas manufacture. Robert Fife. *Gas J.* 228, 78–9, 83–4(1939); *Gas World* 111, 267–9.—Tests were carried out on 2 generators designed to gasify coal either completely or partially. A generator consisted of a vertical retort built on top of the water-gas generator so that the fuel which was charged into the top of the retort would travel down to the generator and on to the coke extractor. When extg. more than 400 lb. of coke per ton of coal charged to a generator with a capacity of 700,000 cu. ft. of gas per day it was frequently found that coal, almost uncarbonized, would appear among the extd. coke. The extractor seemed to be pulling down the central core of coke in the generator. There were indications that an air blast was short-circuiting through the less dense coke in the outer ring adjacent to the generator wall. When the plant was operated with complete gasification the heating value of the gas varied from 290 to 330 B. t. u., but a consistent quality could not be maintained. A generator with a capacity of 150,000 cu. ft. per day responded excellently in respect to gas output and quality. The best results were obtained in a 12-day test during which 500 to 600 lb. of coke was extd. per ton of coal charged. A cycle of 1½ min. blow and 5½ min. up-run, using 5 to 6 lb. of steam per min., was used. Production of a 383 B. t. u. gas amounted to 31,700 cu. ft. per ton.

P. J. Wilson, Jr.

New water-gas plant at Portland, Maine, effects economies. Alfred I. Phillips. *Am. Gas J.* 151, No 4, 21–6(1939). E. H.

Potentialities of future gas-production costs. Leon J Willier. *Gas* 15, No. 11, 15–17(1939).—As a result of a comprehensive study of gas-manufg. processes, the following conclusions were drawn: (1) That the thermal efficiency of present methods used for manufg. gas—coal gas and carbureted water gas—is so high that there is little possibility of materially reducing gas-production costs. (2) That fundamentally the 2 major processes used today in the manuf. of gas are the same as they were when originally developed—with changes and improvements only in design. (3) That a material reduction in gas-production costs is only possible in the production of valuable by-products. (4) That cracking Bunker C oil into gasoline, oil gas and coke; in a regular cracking plant, using the coke for generator fuel, reforming the oil gas and selling the gasoline seems to offer possibilities of a 35 to 40% reduction in the production cost of carbureted water gas. (5) That the max. amt. of gasoline that could be produced by the gas industry by such operation would be a small percentage of the total consumption and would have no effect on the gasoline market. (6) That cracking Bunker C oil as proposed would provide a total market for approx. 50 million barrels of fuel oil per year. R. W. Ryan

A vacuum-cooling system for gas dehydration. W. D.

Shively. *Gas* 15, No. 11, 37–8(1939).—Water cooled by a vacuum produced by steam jets was circulated through an indirect gas cooler of the finned tube type. In this way carbureted water gas compressed to 50 lb. gage was cooled at the holder inlet to 5 to 10°F. below the low temp. of the distribution system, thus partially dehydrating the gas and removing oil condensates. R. W. Ryan

The degree of accuracy of determinations of caloric value of gas by calorimeter. J. A. van Dijk. *Het Gas* 59, 246–50(1939).—A discussion of different types of calorimeters with their possible errors: unequal temp. of the combustion gases and the gas-air mixt. gives an error of ±2 kg.-cal. per cu. m.; difference in the amt. of water vapor entrained with the combustion gases and the amt. taken along by gas-air may produce an error of up to 40 kg.-cal. Radiation losses will occur unless the colorimeter water temp. is 2° lower than room temp. and may amount to 6 kg.-cal. per cu. m., lack of correction for emergent stem on thermometer 15–20 kg.-cal. per cu. m., faulty estn. of thermometer reading ±8 kg.-cal. per cu. m., error in meter 0.5% or ±20 kg.-cal. per cu. m. B. J. C. van der Hoeven

Incomplete combustion and excess air. Niccolò Cesareo. *Arch. Wärmewirt.* 20, 161–2(1939).—Diagrams are given for computing CO in flue gas and excess air ratio when fuel compn. and CO_2 and O_2 in the flue gas are known. Ernest W. Thiele

Total sulfur below 10 grains/100 cu. ft. Practice and results on a 140 million works with the oil-washing process. Norman Hudson. *Gas World* 111, 293–6, 308 11 (1939); *Gas J.* 228, 186, 191, 192–3, 245–8.—The gas, after removal of H_2S, is passed through a rotary brush washer, in which the wash oil is circulated at the rate of 25 gal. per 1000 cu. ft. of gas scrubbed. The enriched oil is treated as in an ordinary benzene plant. The S in the gas is reduced from 22–25 grains down to 7–9 grains per 100 cu. ft. Light oil recovery amounts to 2.5 gal. per ton of coal. P. J. Wilson, Jr.

Origin of lenticular nuclear softening by carbon monoxide. Leopold Breitenecker. *Deut. Z. ges. gerichtl. Med.* 30, 299–305(1939).—Careful observations of coal-gas poisoning showed that contrary to reports of Kalisko and Meixners, softening of the lenticular nucleus appeared in many cases from various Vienna hospitals particularly, if the poisoning had followed a slow course owing to external circumstances. Similar effects due to CO are independent of the toxic period. The Keber formula, poisoning effect equals concn. multiplied by time, is not entirely applicable for CO because the effect produced on the central nervous system by prolonged exposure of a low concn. is greater than that produced during a short interval by high concn. The constancy of localization of softening of the lenticular nucleus is important in medicolegal action. F. K.

The commercial dustproofing of coke. II. Survey of American and European practice. C. H. Noton. *Gas World* 111, 242–3(1939); cf. *C. A.* 33, 7526[5]. P. J. Wilson, Jr.

The influence of the return of fly coke on furnace operation and smoke production of chain grates. P. Noss. *Arch. Wärmewirt.* 20, 233–6(1939).—With coking coals fine combustible recovered from the flue gases can be successfully mixed with fresh fuel. With noncoking coals it is best blown into the furnace from the rear of the grate with secondary air; it then helps to ignite the front of the grate. Examples of this are described. Ernest W. Thiele

The use of coke breeze in producers. S. Qvarfort. *Schweiz. Ver. Gas- u. Wasserfach., Monats-Bull.* 19, 157–62(1939).—In reviewing the literature (e. g., Linsdale and Curtis, *C. A.* 30, 6924[4]) it is pointed out that usually breeze is taken to be coke between 12 and 3 mm. sizes; it has been the author's practice (Stockholm) to use −7-mm. breeze. This material is fired in 10 producers, one Koller, 5 Koppers, 4 AVG type, all of 2.6 m. internal width, conical grate, automatic ash removal, rating varying from 13 to 30 tons of coke per day. With a mixt. of 15–25 mm. coke (11% H_2O, 10% ash) with 33.4% breeze (all through 7 mm., 52% through 3 mm.) (8% H_2O, 14% ash) the daily throughput in a Koller machine was 17.8 tons (gross), lower heating value of gas 1100 kg.-cal. per cu. m., cold efficiency 73.2%, 7.9% carbon in ash. With 32.4% breeze in the same 15–25-mm. coke, breeze with 63% through 3 mm., all through 10 mm., the throughput was 16.8 tons per day in an AVG machine, gas of 1069 kg.-cal., 70.4% efficiency, 12.4% C in ash. With 6–15-mm. coke (9% H_2O, 16% ash) contg. 42.8% breeze (all through 10 mm., 63% through 3 mm., 12% H_2O, 13% ash) a throughput of 13.1 tons per day, 1028 kg.-cal. gas, 69.8% efficiency, 12.4% C in ash was obtained. Expts. with large-size coke contg. breeze showed that a tendency to blowholes appeared (AVG producer) for breeze contents above about 15% and screening out of −12-mm. breeze was necessary. Successful results were obtained with coke of 2.6% on 60 mm., 16.7% 40–60 mm., 32.3% 25–40 mm., 28.8% 15–25 mm., 9.6% 7–15 mm., 10.0% 0–7 mm., gas 1080 kg.-cal. per cu. m., 74.6% efficiency, 22.0 tons per day. In the producers used for the above work the fuel charging was all done with one central bell; only the Koppers producers had a fuel-distribution device. It has been the practice for the last 5 yrs. to add breeze of less than 7-mm. size regularly in amts. of up to 25% of coke of av. size 11 to 20 mm. For an av. throughput of 15 tons per day the allowable amt. of breeze varies with the size of the larger coke and its own breeze content; the max. amt. of material through 7 mm. allowable for this operation is around 30%. The amt. of breeze varies some with the type of producer. During 1938 the amt. of −7-mm. breeze varied between 17.7 and 28.0%, rating 11.5 to 16.5 tons per day, av. C in ash 13.3%, ash in coke (dry) 11.9%, dust loss 0.6%. It is concluded that screening out of −3-mm. breeze dust is not necessary for satisfactory operation. Increased dust content will primarily cause a decrease in rating, secondarily loss in efficiency. Hs. Deringer. *Ibid.* 289.—The above results are confirmed from experience in the Winterthur gas works. In a 2.1-m. producer with a rating of 85 kg. per sq. m. hr. coke of 40% unscreened dust, through 10 mm., was fired. When the 0–1-mm. portion is screened out more dust can be added without difficulties, fractionation of the dust and sandwich charging was found beneficial. At the 85 kg. per sq. m. hr. rating 60% breeze through 12 mm. was used over long periods, the coke analysis being 12% of 1–3 mm., 30% 3–8 mm., 18% 8–12 mm., 40% 12–20 mm., efficiency 75–80%, 4–5.5% CO_2. Small changes in grate construction made it possible to increase the no. of revolutions 50% with improved fire condition (model expts.). B. J. C. van der Hoeven

Regulations on coal-tar colors (Anon.) 12. Heat transfer in the radiant section of [steam heaters] (Lobo, Evans) 1. Waste problems of the Fe and steel industries [production of coke] (Hodge) 9. Brown-coal district in northwestern Bohemia (Pohl) 8. Acidizing gas wells in limestone formations (U. S. pat. 2,171,011) 22. Handling cement slurry in gas wells (U. S. pat. 2,171,840) 22. NH_4NO_3 explosive [for mining coal] (U. S. pat. 2,171,379) 24.

Fuel. Gewerkschaft Mathias Stinnes. Brit. 505,729, May 16, 1939. See Fr. 838,558 (*C. A.* 33, 6567[2]).

Motor fuels. Ivan Lovens. Brit. 506,230, May 24, 1939. The fuels, e. g., gasoline or a mixt. of gasoline, alc., C_6H_6 or heavy oils, are improved by addn. thereto of a product obtained by treating a nondrying oil, e. g., castor, olive, dissolved in a solvent, e. g., C_6H_6, toluene, white spirit, gasoline and MeOH, with O and H brought into contact therewith, e. g., by injection into the soln. Preferably, H and O are used alternately with excess of H. Absorption of the gases is improved by addn. of oleic or caprylic acid, $(AcO)_2Mn$ or C_2H_2 to the oil soln. Antidetonants may be added.

Olefin polymerization for motor-fuel production. Francis M. Archibald (to Standard Alcohol Co.). U. S. 2,171,250, Aug. 29. App. is described, and a process involving passing a mixt. of light hydrocarbons including iso-olefins through a bath of aq. H_2SO_4 of 55 to 85% concn.

at a temp. of from about 60 to 130° whereby polymers are produced, removing the reacted mixt. to a sepn. zone maintained under substantially the same reaction conditions and withdrawing the hydrocarbons from the acid phase.

Use of krypton, etc., for improving combustion in internal-combustion engines. Thomas Marshall, Jr. U. S. 2,169,844, Aug. 15. Combustion of hydrocarbons with air in internal-combustion engines is improved by adding to the fuel-air mixt. a readily ionizable gas such as KA, A, Ne, Xe, or He.

Apparatus for detecting leakage of internal-combustion engine gases, etc. Howe H. Hopkins (to National Carbon Co.). U. S. 2,171,113, Aug. 29. Various structural and operative details.

Apparatus for heating air for the combustion of fuel in suspension. Lambert Kooistra (to Babcock & Wilcox Co.). U. S. 2,170,145, Aug. 22. Various structural details.

Agglomerating fuel. N. V. Persbraadstofsyndicaat Persyn and Leender J. J. Hazelzet. Brit. 506,283, May 24, 1939. Finely divided material, e. g., anthracite, coke dust, brown coal, is mixed with an amylaceous binder and H_2O, kneaded and heated to cook the binder and convert it into a gelatinous paste, the mass being then transferred to another chamber and suddenly subjected to a higher temp. after which it is briquetted. App. is described.

Compressed fuel blocks. Olga Headland. U. S. 2,170,326, Aug. 22. Compressed blocks are formed with lignite and straw and a substantial quantity of alc. and are sealed with paraffin to prevent evapn. of the alc. and to serve as a binder.

Fuel pulverizer suitable for treating fuel fed to furnaces. Paul S. Dickey (to Bailey Meter Co.). U. S. 2,172,317, Sept. 5. Various structural, mech. and operative details.

Treatment of solid carbonaceous material. Hugh Quennell and Frederic Lloyd. Brit. 506,391, May 25, 1939. Noncoking coal is carbonized at 400–500° in an externally heated rotary retort of the kind described in Brit. 454,268 (*C. A.* 31, 1589[7]) and the coke, while still hot, is supplied to the grate of a combustion app. where it is burnt. The gas produced, after extn. of condensible products, is used either in the combustion app. to which the coke is fed, or for heating the retort which may, however, be heated by the waste gases of the combustion app.

Coking or heat-treatment of solid materials. Thomas M. Davidson. Brit. 507,236, June 7, 1939. Addn. to 475,727 (*C. A.* 32, 3590[4]). In a rotary retort of the kind described in 475,727, wherein the charge is heated while compressed into annular channels on the periphery of a cylindrical drum, the drum casing is formed from metal plates jointed to leave gaps between their adjacent edges. The annular members forming the lateral walls of the channels have a clearance from the periphery of the casing and have inwardly extending projections that engage in the gaps.

Carbonizing processes. Humphreys & Glasgow Ltd. and Eric C. Mengel. Brit. 506,994, June 5, 1939. In processes for carbonizing material, e. g., coal briquets, by circulating heated gas therethrough as described in Brit. 469,175 (*C. A.* 32, 753[2]), the material is charged in batches into a carbonizing chamber and rapidly discharged therefrom in batches into a rest chamber closed to the atm., the material being slowly discharged from the rest chamber, e. g., by a slow-running conveyor.

Firing soaking pit of other furnaces with a gas such as natural gas. Geo. M. Parker. U. S. 2,172,105, Sept. 5. A furnace structure is described and a method of firing a furnace with hydrocarbon gas of high calorific value consisting in, preliminarily heating a furnace reaction zone adapted to store and transfer heat to 925–1200°, then conducting hydrocarbon gas of high calorific value and preheated air into the zone, the ratio of gas to air being such as to effect the burning of part of the gas by the air and the reforming of the balance of the gas, with the formation of final products of a comparatively low calorific value and contg. a substantial amt. of free C, adding preheated air to the final products, burning the resultant mixt. in the furnace laboratory and controlling the character of the resultant flame by hydrocarbon gas of high calorific value fed into the laboratory under comparatively high pressure.

Firing furnaces, such as those used for melting glass, etc., with natural gas. Geo. M. Parker. U. S. 2,171,597, Sept. 5. Furnace details are described, and a method of firing a regenerative furnace with natural gas, which consists in introducing to a regenerative chamber, a mixt. of gas with an amount of air distinctly less than the theoretical proportion for complete burning of the gas, maintaining a zone in such chamber at a temp. of an order of 925–1200° to effect partial decompn. and reformation of the gas, exposing the gas-air mixt. to such temp. for a time effective to dissociate it into products including H and CO, with the H substantially preponderating in volume, and also including substantial amounts of free carbon, so that the reformed gas approximates the characteristics of producer gas, maintaining the reformation zone sufficiently free of O and CO_2 throughout the process, to avoid appreciable oxidation of the free carbon resulting from dissociation of the hydrocarbon content of the natural gas, adding air at the burner in a quantity sufficient to provide for complete combustion of the reformed gas and free carbon, in passing a portion of the hot gases resulting from complete combustion through an alternate regenerative chamber, and alternately utilizing a portion of the last said chamber as a high-temp. zone and therein effecting a continuation of said partial decompn. and reformation of the gas for further fuel supply to the furnace.

Continuous process of reforming natural gas. Geo. M. Parker. U. S. 2,171,596, Sept. 5. An arrangement of app. is described, and a continuous process of gas-making consisting in, preliminary heating a heat-transfer medium in a vessel to about 870–1200°, then internally heating said medium and simultaneously conducting natural gas and air into the vessel and into contact with the heat-transfer medium, the ratio of gas to air being such as to effect the burning of part of the natural gas by the air and the reforming of the balance of the natural gas into gas of lower B. t. u. heating value than natural gas, and with the formation of final products of a B. t. u. heating value corresponding to that of producer gas, the internal heating being to such an extent as is necessary to maintain the said temp. conditions and to effect the mentioned results.

Continuous process of gas making. Geo. M. Parker. U. S. 2,172,106, Sept. 5. App. is described, and a continuous process of gas-making consisting in, preliminarily heating a heat-transfer medium in a vessel to 870–1200°, and then applying heat to the medium internally of the vessel and conducting hydrocarbon gas of high B. t. u. heating value and air into the vessel and into contact with the heat-transfer medium, the ratio of gas to air being such as to effect the burning of part of the gas by the air and the reforming of the balance of the gas into gas of comparatively low B. t. u. heating value, with the formation of some carbon, and concurrently admitting steam to the vessel for reaction with said carbon to form blue water gas, with the formation of final products of a B. t. u. heating value of approx. from 120 to 160, the mentioned internal heating being to such an extent as is necessary to maintain the said temp. conditions and to effect the mentioned results.

Water-gas generation. Arthur R. Griggs. Brit. 505,724, May 16, 1939. In the back-running of a carbureted water-gas set by steam admitted to the superheater, the whole of the carburetor, or the upper part thereof, is bypassed by admission of steam to the generator through a pipe that connects the superheater directly or the lower part of the carburetor to the top of the generator. In Brit. 505,789, May 17, 1939, app. for the production of gases, e. g., water gas, by cyclic operation has the outlet side of a valve controlling the flow of air or other combustion-supporting gas subjected, when closed, to a cushion of steam pressure to prevent leakage therefrom or leakage of combustible gas therethrough in the reverse direction.

Oil-gas generators. Foreign Patent Rights, Inc. Brit. 506,776, June 5, 1939. These comprise a chamber housing a moving absorbent means to carry the oil into a combustion space for partial combustion with a controlled mixt. of air and steam, together with a chamber contg. metallic or nonmetallic disks having a catalyzing action to which the gases and vapors from the combustion space are admitted and issue therefrom as a fixed gas. The temp. of the gases in the combustion space is 1800–2800°F. and this temp. is reduced to less than one-third after passage through the catalyzing chamber.

Gas generator utilizing air and a liquid fuel such as gasoline. Wm. R. Robinson. U. S. 2,171,893, Sept. 5. Various structural and operative details.

Apparatus for generation and distribution of gas from materials such as liquefied butane and propane. John T. Dockery (40% to James P. McKey and 60% to Ernest L. Shelton). U. S. 2,172,021, Sept. 5. Various structural and operative details.

Power plant comprising a gas producer and gas engine. James Macdonald. U. S. 2,171,184, Aug. 29. Means are provided for causing a disproportionate variation in the ratio of water to air supplied to the engine while it is adjusting itself to a change in power demand and for thereafter maintaining the ratio of water to air at a valut appropriate to the new demand.

Converting hydrocarbon gas to carbon monoxide and hydrogen. Ernst Karwat (to Linde Air Products Co.). U. S. 2,170,265, Aug. 22. Various details of app. and operation suitable for effecting reaction of a C_nH_4-bearing gas with steam and O in heated coke.

Removing carbon monoxide from gases. Richard Brandt. Brit. 507,120, June 9, 1939. Addn. to 490,920 (*C. A.* **33**, 1478[8]). The method of 490,920 is modified by adding to the initial gas part of the main gas after its subjection to the steam catalysis, so as to allow for the variation of combustible gas produced, e. g., in the coke ovens. The addn. is particularly necessary during charging and discharging of the ovens. The added gas may be freed from CO_2 before admixt. and may be added to the initial gas before the latter is purified from H_2S. An addnl. catalyst that differs from the 2 catalysts of the process of 490,920 may be interposed between them or arranged between the 2 layers of the main catalyst, in order to obtain a refining of C_6H_6 hydrocarbons in combustible gases contg. them in addn. to CO.

Tar acids or phenol from tar oil, etc. Hubert L. Stewart (to Koppers Co.). U. S. 2,172,415, Sept. 12. A cyclic process for producing tar acids or phenol from tar oil or phenol-bearing material involves electrolyzing a Na_2CO_3 soln. in a cell having anolyte and catholyte compartments to produce NaOH in the catholyte compartment and $NaHCO_3$ in the anolyte compartment, continuously withdrawing the NaOH produced and with it producing tar acid salts or phenolates by reaction with tar oil or phenol-bearing material, similarly withdrawing and using the $NaHCO_3$ produced with production of Na_2CO_3 and returning the latter for further regeneration of the anolyte and catholyte solns. App. is described.

Coke ovens. Woodall-Duckham (1920) Ltd. and Francis B. Richards. Brit. 507,574, June 16, 1939. In a concrete supporting-plate for a coke-oven battery comprising a no. of sections supported at their transverse edges on pillars or arches in a manner that leaves expansion gaps, the plates are located relative to the pillars by projections on the latter that engage recesses on the plate edges, projections on intermediate rows of pillars engaging central recesses, and both projections being continuous with raised ribs on the plates built into the battery along its center line and preventing lateral movement of the plates.

Coke ovens. Woodall-Duckham (1920) Ltd. and Francis B. Richards. Brit. 507,576, June 16, 1939. In a coke-oven battery wherein the masonry is free to expand on a supporting pad, the pad is keyed to the masonry by a raised rib extending lengthwise of the battery.

Coke ovens. Woodall-Duckham (1920) Ltd. and Arthur T. Kent. Brit. 507,577, June 16, 1939. In a coke-oven battery supporting pad provided with transverse expansion gaps above alternate rows of edge-supporting pillars, the pad sections are formed integrally with intermediate rows of pillars, outer pillars of which are free if desired.

Regenerative coke ovens. Dr. C. Otto & Co. G. m. b. H. (to Carl Otto). Brit. 507,530, June 16, 1939. In an oven for producing gas and coke and provided with vertical heating-flues, the partition walls sepg. the regenerator chambers are provided with metal inserts to oppose the flow of gas between the chambers.

Coke-oven bracings. Woodall-Duckham (1920) Ltd. and Francis B. Richards. Brit. 507,575, June 16, 1939. A coke oven is braced by buckstays and longitudinal tie-rods, the lower rods being located beneath a composite supporting-plate formed with transverse expansion joints.

Coke-oven doors. Gustaf Edwin Salkvist (to Koppers Co.). Brit. 506,449, May 30, 1939.

Coke-oven door-operating mechanism. Gustaf Edwin Salkvist (to Koppers Co.). Brit. 506,448, May 30, 1939.

Coke-oven charging-hoppers. Heinrich Koppers G. m. b. H. (to Heinrich Koppers' Industrieele Maatschappij N. V.). Brit. 506,020, May 22, 1939.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER AND STEWART S. KURTZ, JR.

Waste problems in the petroleum industry. J. Bennett Hill. *Ind. Eng. Chem.* **31**, 1361–3(1939).— A review.
G. G.

Extraction of oil from asphaltic rocks and bituminous schist. Giorgio Roberti. *Ricerca sci.* **10**, 532–9(1939).— A discussion.
W. F. Bruce

Study of paraffins and petrolatums. Louis. *Bull. assoc. franç. techniciens pétrole* No. **45**, 31–6(1938).— Paraffins and petrolatums were fractionated under cathodic vacuum to ascertain the nature of their compn. and the distn. is followed by means of graphs. The Pechelbronn and Iran paraffins distil within a few degrees of each other. The petrolatums, on the other hand, had a wider but uniform boiling range and gave a larger distn. residue. The m. ps. and d. of the paraffin fractions increase regularly with the temp. The petrolatum produces solid hydrocarbons which differ from the normal paraffin hydrocarbons and oily constituents whose fluidity ranges from that of light oils to that of gels. The mol. wt. of the latter exceeds that of the original petrolatum. By solvent extn. of the petrolatum both solid and liquid products were obtained. The residue has an ointment-like appearance. Properties of the fractions are tabulated.
E. J. Mahler

X-ray spectrography of petrolatums. C. L. Alexanian. *Bull. assoc. franç. techniciens pétrole* No. **45**, 43–6(1938).— Petrolatum fractions furnish x-ray spectra as clearly as paraffins. The law of the no. of C atoms is applicable to petrolatums, but the intensity and no. of lines diminish regularly toward the end of the fractions studied and disappear entirely in the spectrum of the residue. The length of the chain revealed (33 to 49 C atoms) is greater than that appearing from the numerical value of the mol. wt. detd. by the cryoscopic method. It is the longest chains distributed in the mass of each fraction which impose their action upon the course of diffraction by the x-rays. Individual constituents of paraffins or petrolatums cannot be distinguished by diffraction spectra and lines of orientation except with a highly purified higher fraction.
E. J. Mahler

Absorption process of natural gasoline extraction. R. W. Machen. *Petroleum Engr.* **10**, No. 13, 47–8(1939).—

The present status of the process in the U. S. is stated. Filler-type, perforated plate and bubble-cap absorber towers are compared as to efficiency. The process is briefly described. E. J. Mahler

Examination of mineral oil wax crystals in polarized light. Burdet-Berthod. *Bull. assoc. franç. techniciens pétrole* No. 45, 37–42(1938).—Distillates extd. from Alsatian oil are classified into 2 groups: the lighter which are dewaxed on the filter press, and the more viscous distillates which are centrifuged. By microscopic examn., under polarized light, it is observed that the lighter distillates contain wax in the form of long ribbon-like crystals whose dimensions decrease as the viscosity increases. The wax contained in the viscous distillates is in the form of very thin plates. Centrifuging is started the minute long needle crystals begin to appear. Before dewaxing star-like crystals are also found in the distillate. Solvent dewaxing of the light distillate gives a slack wax which is readily sweatable, while the viscous distillate produces a foots-oil which is preferably redistd. to a distillate contg. large ribbon crystals. E. J. Mahler

Properties of wax residues from crude oil. E. Casimir and C. Creangă. *Petroleum Z.* 35, 511–17(1939).—The phys. and chem. properties of waxes obtained from paraffinic crude oils were studied. They contain 77–96% hydrocarbon., the balance being composed of resins, asphaltic materials and impurities. The hydrocarbon content comprises 21–48% higher hydrocarbons m. 91–92°, difficultly sol. in gasoline, Et_2O and other org. solvents, but sol. in $CHCl_3$ from which it is pptd. by abs. alc. at 20°. It is this fraction which forms the hard ceresin. The waxes also contain 6–13% of solid hydrocarbons m. 57–60° which make up the soft ceresin. The remainder of the hydrocarbons are liquids. The hard ceresin from wax resembles ceresin from ozocerites in appearance, sp. gr., soly., absorptive properties, etc. The retention no., which is an indication of the liquid-takeup of ceresins, etc., is defined as the loss of wt. of the ceresin by vaporization in percentage of the amt. of solvent employed. Analytical results are tabulated. Edward J. Mahler

Cracking of ozocerite at ordinary pressure in the presence of aluminum chloride. C. Otin and G. V. Cotruta. *Petroleum Z.* 35, 561–7(1939).—Rumanian ozocerite having the following properties m. p. 70.5°, d^{22} 0.9395, C 85.7, H 13.77 and S 0.14% was cracked in the presence of 2, 5, 15 and 25% $AlCl_3$. The products were distd. at atm. pressure at the rate of 1 drop every 3–6 sec., washed with NaOH and H_2O and dried over $CaCl_2$. The purified product was then weighed and fractionated into gasoline fractions boiling up to 150° and kerosene fractions b. 150–270°, and residue. From a study of the yields the following conclusions are made: The greater the amt. of catalyst the smaller the yield of liquid product, e. g., 300 g. of ozocerite with 2% catalyst yielded 210 g. liquid as against 135.7 g. with 25%. The yield of both gasoline and kerosene decreased with increasing amts. of catalyst except when 2% $AlCl_3$ is used in which case the gasoline yield was much lower than in the other expts. while the kerosene yield was much higher. As the amt. of catalyst was increased the d. of the fraction boiling in the same range decreased. The yield of unsatd. compds. (detd. by the P_2O_5-H_2SO_4 method) decreases with increasing amt. of catalyst. Exptl. results and properties of the products are tabulated. E. J. Mahler

Performance tests of lubricating oils in automobile engines. H. A. Everett and F. C. Stewart. *Penna. State Coll. Bull., Eng. Expt. Sta. Ser., Bull.* No. 44, 50 pp. (1939). E. H.

Influence of volatility and viscosity on the consumption of lubricating oils. C. A. Bouman. *IIme Congr. mondial pétrole* 3, Sect. 4, 487–93(1937)(in French).—Various internal-combustion engine and Diesel engine oils were tested under actual service conditions to det. the effect of the volatility and viscosity of the oil on oil consumption. The general conclusion is drawn that influence of volatility and viscosity on consumption depends to a large extent on the state of the engine and on operating conditions. Usually a decrease in the viscosity of the oil produces greater consumption, but the relation between volatility and consumption is not at all pronounced. E. J. M.

Lubricating-oil addition agents. E. Thomas. *Bull. assoc. franç. techniciens pétrole* No. 45, 49–66(1938).—The proper qualities which a good lubricant should possess and the methods employed by the refiner to produce such a lubricant are mentioned. Oiliness and friction resistance of a lubricant are discussed and methods used in the detn. of the coeff. of friction with extreme-pressure lubricants are described, e. g., the Martens, Wells, Woog and Charon methods. The use of fatty acids, various esters, and halogenated fatty acids to improve the oiliness of an oil and reduce friction is mentioned briefly, as is the use of antioxidants, viscosity-index improvers and pour depressors. A table is given showing the effects of the addn. of Paraflow to a mineral oil. E. J. Mahler

Recent developments in Diesel lubricating oils. G. L. Neely. *S. A. E. Journal* 45, 485–500T(1939).—Performance data are given and a new compounded oil is described. An important characteristic is the "limiting adhesion temp.," above which a given oil does not wet a metal surface with a fluid film of sensible thickness. H. A. Beatty

New Diesel lubricant using Ten-ol compound. A. C. Vobach and Faithe. *IIme Congr. mondial pétrole* 3, Sect. 4, 458–70(1937)(in English).—Ten-ol compd. is prepd. by condensing 1 part of unsatd. aliphatic acid with 2 parts by vol. of aromatic hydrocarbon at 135–50°F. in the presence of $AlCl_3$. The reaction product is washed free of sludge with HCl and steam distd. to recover an overhead product consisting mostly of a substituted fatty acid and some satd. fatty acid, and then sapond. with lime to produce a compd. contg. 1–2% of lime soap. This Ten-ol compd. is then blended with Diesel oils. Properties of Ten-ol Diesel oils and uncompounded oils are tabulated. A test program is described in which the compounded oil was compared with (1) a highly treated stable paraffinic oil, (2) a Gulf Coast naphthenic lubricant, (3) a high-S Smackover lubricant and (4) a 42% raffinate from solvent-treated Gulf Coast lubricating distillate. Lab. inspection tests for these oils are tabulated. Test results for all oils are given showing: total hrs. run, rate of oil consumption, time of blow-by increase, method of inspection during test, reason for shut-down, filter condition, cylinder and piston wear. The Ten-ol oil run lasted 1093.5 hrs. and pistons, rings, and liner were in exceptionally good condition at its completion. E. J. Mahler

Deterioration of lubricants in Diesel engines. Linc. *IIme Congr. mondial pétrole* 3, Sect. 4, 500–13(1937)(in French). After discussing the characteristics of deposits formed on aging and the factors entering into the service qualities of a lubricant, L. gives a summary of the observations made on the nature and extent of deterioration of Diesel lubricants in high-speed, mech. injection engines. Tables are given showing the complete analyses of the oils used in the aging tests. Tables are also given showing the results of analyses of oils used in Diesel motors with precombustion chambers, air reserves, turbulence chambers and direct injection. E. J. Mahler

Measurement of surface temperatures under extreme-pressure lubricating conditions. H. Blok. *IIme Congr. mondial pétrole* 3, Sect. 4, 471–86(1937)(in French).—A math. method is explained in which the temp. is shown to be proportional to $Cf\sqrt{P}V$, where P is the mean pressure, V the gear engaging speed, f the coeff. of friction and C a const. The surface temps. of several types of gears under extreme-pressure conditions have been calcd. and in some instances reach several hundred degrees. A method for calcg. the temp. at all speeds and a method of approx. calcn. are outlined in an appendix. E. J. Mahler

Testing extreme-pressure lubricants. W. J. D. van Dijck and H. Blok. *IIme Congr. mondial pétrole* 3, Sect. 4, 445–51(1937)(in French).—An improved testing device based on the four-ball method is described and its functioning explained. In this method 3 steel balls are clamped together and held at rest in a cup while a fourth ball spinning at a speed of about 1500 r. p. m. is pressed against

them. The friction torque is registered and the wear of the balls is measured for various loads. Two tests are employed, one run for 60 sec. with a heavy load—the so-called minute test—and the other run for several hrs. under a lighter load. Wear curves of typical extreme-pressure lubricants and photographs of wear areas on the balls are given. The efficiency of the method is discussed and compared with other methods. E. J. Mahler

Lubrication of ammonia compressors. C. H. S. Tupholme. *Ice and Cold Storage* **42**, No. 494, 73–5(1939).—A satisfactory oil must not congeal, must not break down and form gummy deposits or gaseous products and must be of sufficient body to lubricate and seal the compressor piston against leakage and avoid being readily atomized or swept out of the cylinder by the flow of refrigerant and so be carried through the system and deposited in the condensing or expansion coils. A. H. Johnson

The effect of extreme viscous friction on the surfaces of propeller blades. Henri Brillié. *Bull. soc. roy. belge ing. ind.* **1939**, 579–621.—A review of erosion and lubrication phenomena and the related theories. The relationship of phys. and chem. properties to lubrication is discussed. S. Bradford Stone

Purification of used motor oils. E. H. Edmund Gracfe. *IIme Congr. mondial pétrole* **3**, Sect. 4, 452–4(1937)(in German).—The main purpose in regenerating used lubricating oils in motor service is to remove foreign matter, e. g., by sedimentation, filtration or centrifuging. G. believes that the oil does not suffer so much as is thought from aging, emulsification and change in color. The extensive use of bleaching earths to restore the color of the oil to its original color is not advised. E. J. Mahler

Measuring the extent of dilution of used motor oils. Boisseaux. *IIme Congr. mondial pétrole* **3**, Sect. 4, 455–7 (1937)(in French).—Two methods are compared, viz., evapg. the volatile materials in a bath heated to 105–110°, and observing loss of wt., and second, distg. the volatile materials with steam and reading off the amt. of volatile matter after condensation. For engines operating on light motor fuels such as gasoline with or without alc., the loss of wt. method gives best results. However, with engines running on gas oils the second method called the "dilution trap" method (A. S. T. M. D-322-35) is more suitable. Test results are described for oils purposely dild. and for oils dild. in actual service. E. J. Mahler

Identification and analysis of asphalts. H. Suida and F. Motz. *Petroleum Z.* **35**, 527–33(1939).—It is pointed out that the present methods employed in the analysis of asphalts, e. g., fractional soln. or adsorption give only arbitrary results depending upon the solvents employed and the exptl. conditions. The authors describe and discuss a method comprising the following steps: The asphalt is first extd. with $CHCl_3$ at 20° to remove residual mineral oil and oil resin. Next follows a treatment with C_5H_5N at 20° to ext. residual asphaltic resin, and lastly, a similar pyridine extn. at 50° to remove residual hard asphalt. All extns. take place in an O_2-free medium and in the presence of continuously stirred adsorbent material e. g., fuller's earth. The method was tested on 4 asphalts, viz., Rumanian 200, Ebano 200, Spramex 200 and Selenizza natural asphalt with good results. Exptl. data are tabulated. The app. is shown diagrammatically. 30 references. Edward J. Mahler

Uses of bitumen in the cable industry. S. Beckinsale and A. King. *IIme Congr. mondial. pétrole* **3**, Sect. 4, 435–44(1937)(in English).—Natural and petroleum residual bitumens and compds. contg. them are widely used in: vulcanized cables, fiber-insulated cables, cable joint box compds., including terminal and outer boxes, insulating tapes, and protective coverings for cables and accessories. They have excellent dielec. and phys. properties. Blown asphalts, though used as constituents of some box compds., have not been used to any great extent for waterproofing cables owing to disappointing results obtained. Bitumen contg. appreciable quantities of wax break down under weathering conditions and their use must be avoided. The following properties of cable joint box compds. are discussed in some detail: soly. in CS_2, softening point, pour point, elec. strength, flash point, penetration, mineral content, segregation, S, acid and water content, power factor, specific insulation resistance and specific inductive capacity. E. J. Mahler

Heat transfer in the radiant section of petroleum heaters (Lobo, Evans) 1. Polarographic method for detg. org. peroxides [in studying cracking gasolines and oils] (Dobrinskaya, Neiman) 7. Corrosion- and heat-resisting steels [used in oil refining] (Thompson) 9. Detn. of mol. wts. of high-boiling oil fractions (Rankaya, Shchegrova) 2. Stability of bitumen emulsions (Korzhuev, Gridchina) 2. Dimerization of petroleum hydrocarbons (Sparks, *et al.*) 10. App. for heating liquid bitumen (Brit. pat. 506,392) 1. App. for dispensing gasoline or oils (U. S. pat. 2,171,707) 1. Float-valve device for metering fuel oil (U. S. pat. 2,171,620) 1. Liquid hydrocarbons from olefinic gases (U. S. pat. 2,171,522) 10.

Pumping and agitating apparatus suitable for effecting oxidation of petroleum oils with air for producing asphaltic products. Earle W. Gard and Blair G. Aldridge (to Union Oil Co. of Calif.). U. S. 2,170,496, Aug. 22. Various structural and operative details.

Acidizing petroleum-producing formations in oil and gas wells. Robert E. Lee (to Lee Angular Drill Corp.). U. S. 2,171,416, Aug. 29. App. is described, and a method of acidizing petroleum-producing formations which consists initially in boring a vertical hole, then in drilling a plurality of angular openings at predetd. levels and angles from and with respect to the vertical bore hole, in packing off selective groups of said openings, in introducing into unrestricted groups of openings an acidizing agent through said bore hole, in changing the position of the discharge point of said agent with respect to the packing to obtain access to companion groups of openings and in introducing said acidizing agent.

Sulfonated mineral oils rich in sulfur content. Erich A. Wernicke (to Ichthyol Co.). U. S. 2,172,149, Sept. 5. By a process such as described in U. S. 2,121,845 (*C. A.* **32**, 6453[6]), there are obtained sulfonated S-bearing mineral oils which have their original S content substantially unimpaired, of light yellow-brown color, substantially free from objectionable odor, and clearly water-sol. Various examples with details of procedure are given.

Oil refining. Heliodor Rostin and Karl Schuster. U. S. 2,171,009, Aug. 29. In a continuous process, oil vapors, such as those of oils from coal or shale or naphtha oils, and reducing gases such as H or CO are conducted over the oölitic ore, minette, in the presence of steam and at a temp. of 300–450°, the proportion of reducing gases and steam being so adjusted that released S escapes from the reaction chamber in the form of H_2S and does not form permanent sulfide of Fe in the chamber.

Cracking oils. Hans G. Tovote. Brit. 506,532, May 30, 1939. The solidification point of hydrocarbon mixts. contg. paraffin wax is lowered by preheating the raw material, e. g., petroleum residues or distillates, to 752–896°F. and passing it into contact with masses having an extensive surface area for a regulated time of 10–60 min., the temp. and duration of the contact being regulated so that the formation of fractions boiling below 356°F. is restrained. Specified contact materials comprise gas cokes, cokes produced by carbonizing lignites or cracking lignite tars or mineral oils, pumice, blast-furnace slags, limonite, oölitic Fe ore, bauxite or cokes covered with Na silicate. Pressures of 83–440 lb. per sq. in. are used. App. is described.

Cracking and reforming oils. Universal Oil Products Co. Brit. 506,785, May 30, 1939. Divided on 501,560 (*C. A.* **33**, 6037[8]). Hydrocarbon oils are cracked and the cracked vapors are subjected to fractionation in 2 successive stages to recover gasoline fractions of desired boiling range, the fractionation in the 2nd stage being conducted in presence of gasoline fractions introduced from an extraneous source so as to sep. a gasoline fraction of desired boiling range and a heavier fraction which is subjected to

reforming and subsequent fractionation to produce a gasoline of high antiknock value. The cracking stage may comprise a single cracking coil but preferably heavy and light fractions are isolated in the primary fractionating tower of the system as a side cut taken off through a line and as reflux taken off through another line from the bottom of the tower, and these fractions are cracked separately in coils under conditions of temp. and pressure suitable to the respective fractions. App. is described. 1

Cracking and reforming oils. Universal Oil Products Co. Brit. 506,849, June 6, 1939. In a process for cracking and reforming oils comprising a distillate stock consisting substantially of gasoline of low antiknock value, the oils are cracked and reformed in presence of gaseous hydrocarbons and after immediate cooling to arrest further conversion the products formed are fractionated to sep. gasoline of required antiknock value, which is stabilized, the rich gases thus released being absorbed in an oil which is then subjected, together with the absorbed gases, to the cracking step. App. is described. 2 3

Cracking hydrocarbon oils such as topped crude oil. Bernard L. Krämer (to Universal Oil Products Co.). U. S. 2,170,333, Aug. 22. An arrangement of app. is described, and a process wherein an oil of relatively high b. p. is heated to cracking temp. at superatm. pressure in a heating coil, an oil of relatively low-boiling characteristics simultaneously heated to an independently controlled higher cracking temp. at superatm. pressure in a sep. heating coil, resulting heated products from both heating coils are passed through substantially the entire length of an enlarged insulated reaction chamber, also maintained at superatm. pressure, wherein they are subjected to continued cracking, the resulting vaporous and liquid conversion products withdrawn from the reaction chamber and introduced into a reduced pressure vaporizing and sepg. chamber wherein vaporous and residual liquid conversion products are sepd. and wherefrom they are separately removed, the vaporous conversion products subjected to fractionation for the formation of relatively high boiling and relatively low boiling reflux condensates which are returned, respectively, to the first-mentioned and second-mentioned heating coils for further cracking, fractionated vapors of the desired end-b. p. subjected to condensation and the resulting distillate is recovered; this comprises passing fresh charging oil for the process in indirect heat exchange with vaporous products undergoing the fractionation, commingling the thus preheated charging stock with the high-boiling reflux condensate, supplying the commingled materials to the first-mentioned heating coil and passing the low-boiling reflux condensate, prior to its introduction into the second-mentioned heating coil, first, in indirect heat exchange with the vaporous conversion products in the vaporizing chamber and then in indirect heat exchange with the vaporous and liquid conversion products prior to their introduction into the vaporizing and sepg. chamber. 4 5 6 7

Treating cracked hydrocarbon vapors. Horace B. Cooke and Malvin R. Mandelbaum (to Gray Processes Corp.). U. S. 2,172,436, Sept. 12. An arrangement of app. is described, and a method of treating cracked hydrocarbon vapors comprising motor fuel, to remove undesirable gum-forming constituents and impart improved qualities which comprises subjecting the vapors to contact with solid adsorbent catalytic material in a treating zone to effect polymerization of undesirable gum-forming constituents to products having b. ps. higher than that of the desired motor-fuel product, sepg. from said vapors said high-boiling polymers, thereafter condensing the treated vapors, intimately bringing said vapors prior to the aforesaid condensation thereof into contact with a liquid solvent to remove said high-boiling polymers therefrom, said solvent being a hydrocarbon deriv. capable of functioning as a valuable addition ingredient to the treated motor-fuel product to improve the properties thereof, controlling temp. and pressure conditions of said vapors during contact with said solvent to incorporate a portion of said solvent in the treated vapors, and controlling temp. and pressure conditions during condensation of said vapors to effect retention of a portion of said solvent in the condensate. Fuller's earth may be used as a catalyst. 8 9

Fractionating cracked vapors. Universal Oil Products Co. Brit. 506,784, May 30, 1939. Divided on 501,560 (*C. A.* **33**, 6037[8]). In a 2-stage process for the fractionation of cracked vapors comprising 1st- and 2nd-stage fractionating towers, the fractionation in each stage being controlled by recirculating condensate obtained from vapors passing to a subsequent stage, the gases and light vapors remaining uncondensed in the separators are subjected to further strong cooling in coolers to condense substantially all normally liquid components and the condensate obtained is sepd. from gases in a separator and subjected to stabilization. App. is described.

Treating cracked hydrocarbon oil distillates. Jacque C. Morrell (to Universal Oil Products Co.). U. S. 2,170,336, Aug. 22. In order to obtain a refined gasoline, a cracked-oil distillate while in heated vaporous condition is treated with H_2SO_4 contg. a monocarboxy org. acid of relatively low volatility such as chloroacetic acid or sulfanilic acid at a subatm. pressure.

Conversion of hydrocarbon oil. Claude W. Watson (to Texas Co.). U. S. 2,170,169, Aug. 22. An arrangement of app. is described, and a process which comprises introducing a stream of oil comprising liquid and vaporous constituents at cracking temp. into the upper part of an enlarged cracking chamber, maintained at a cracking temp under superatm. pressure, wherein liquid is prevented from accumulating, passing a condensate stock through a heating coil wherein the condensate is heated to a cracking temp. and utilizing the resultant heated products to constitute at least a portion of the stream of oil introduced into the upper part of the enlarged cracking chamber so that conversion of the hydrocarbons occurs by means of the heat supplied by the heated products, causing vapors and nonvaporized oil to flow downwardly in an unobstructed path through the cracking chamber, removing resultant products comprising vaporous and liquid constituents from the lower part of the cracking chamber and introducing them into the lower part of a subsequent cracking chamber wherein conversion is continued and wherein vaporous products rise in an unobstructed path, maintaining the subsequent cracking chamber at a cracking temp. under superatm. pressure, removing liquid residue from the lower part of the subsequent cracking chamber at a rate adequate to prevent the accumulation of liquid therein, removing sepd. vapors from the upper part of the secondary cracking chamber and passing the vapors to a fractionating zone where they are fractionated to sep. out a condensate and subjecting the condensate to cracking. 4 5 6

Dewaxing hydrocarbon oils. Leo D. Jones (to Sharples Corp.). U. S. 2,172,320, Sept. 5. App. is described, and a method of dewaxing a hydrocarbon oil stock which comprises diluting such stock with a solvent consisting of a low-boiling liquid Cl deriv. of an aliphatic hydrocarbon having a higher sp. gr. than the oil stock and with a hydrocarbon diluent of relatively low viscosity in a proportion of at least 25% by volume of hydrocarbon diluent to 75% by volume of normally liquid Cl deriv. diluent, feeding the mixt. so formed to a centrifugal bowl provided with a circumferentially extending filter surface at a temp. sufficiently low to effect pptn. of the major portion of the wax from the soln., sepg. the major portion of the wax from the soln. by centrifugal subsidence while a sufficient volume of oil is maintained within the bowl to avoid accumulation of substantial quantities of wax upon the filter surface, and finally discharging residual oil from the bowl and thereby projecting pptd. wax against the filter surface and separating said wax from such residual oil by filtration. 7

Dewaxing mineral hydrocarbon oils. Albert Schaafsma and Johannes M. Verstaeg (to Shell Development Co.). U. S. 2,170,508, Aug. 22. A process for dewaxing oil by mixing a liquid dewaxing agent of high solvent power for the oily components of the wax-bearing oil but low solv. for its waxy components involves the use of a mixt. of trichloroethylene and $\beta\beta'$-dichloroethyl ether as the de-

waxing agent and chilling of the treated oil mixt. to ppt. waxy components and sepn. of the material thus pptd.

Treating hydrocarbon vapors with zinc chloride for degumming. Franklin E. Kimball. U. S. 2,171,033, Aug. 29. A process is used which comprises bringing hydrocarbon vapors, contg. gum-forming impurities, into contact with a fused treating mixt. contg. approx. 70% $NH_4Zn_2Cl_5$ to prevent sepn. of $ZnCl_2$ and contg. approx. 30% $ZnCl_2$ to prevent sepn. of $NH_4Zn_2Cl_5$ at a temp. below 250° and at a temp. above the fusion temp. of the treating mixt., supplying $NH_4Zn_2Cl_5$ and $ZnCl_2$ to the treating-mixt., sepg. and withdrawing the hydrocarbon vapors from the treating mixt., withdrawing from the treating mixt. a mixt. of $NH_4Zn_2Cl_5$ and $ZnCl_2$ contg. products of treatment, partially liquefying the withdrawn hydrocarbon vapors to degum the hydrocarbon vapors, sepg. and withdrawing the degummed hydrocarbon vapors from the gum-contg. hydrocarbon liquid and withdrawing the gum-contg. hydrocarbon liquid. 3

Inhibiting gum formation in cracked gasoline. Geo. W. Ayers, Jr. (to Gasoline Antioxidant Co.). U. S. 2,171,780, Sept. 5. Formation of gummy substances during storage is retarded by the addn. of about 0.06–0.3% of a polyhydroxyphenanthrene compd. such as dihydroxyphenanthrene.

Gasoline hydrocarbons from gaseous hydrocarbons. Jacque C. Morrell (to Universal Oil Products Co.). U. S. 2,169,809, Aug. 15. A process for producing gasoline-boiling hydrocarbons from normally gaseous isoparaffin and olefin hydrocarbons comprises simultaneously bringing a normally gaseous isoparaffin and a normally gaseous olefin into contact with H_2SO_4 at a controlled reaction temp. and correlating the amt. and concn. of the acid, the reaction temp. and the proportion of olefin to isoparaffin to effect alkylation of the isoparaffin with the olefin as the principal reaction in the process with min. olefin polymerization, thereby chemically combining the normally gaseous isoparaffin and olefin to form a heavier hydrocarbon boiling in the gasoline range.

Gasoline from normally gaseous hydrocarbons. Frederick E. Frey (to Phillips Petroleum Co.). U. S. 2,170,367, Aug. 22. An arrangement of app. is described, and a process for the conversion of normally gaseous hydrocarbon mixts. contg. satd. and unsatd. hydrocarbons, such as those from oil cracking, into normally liquid hydrocarbons of the gasoline range which involves subjecting such a mixt. to a first thermal conversion step under 500–3000 lb. per sq. in. pressure at a temp. of 370–540° for a time to effect an optimum yield of normally liquid hydrocarbons, sepg. the latter from assocd. gases at 260–455° and at a pressure not greater than that of the first step and subjecting the remaining normally gaseous hydrocarbons sepd. to a second conversion at a pressure above 200 lb. per sq. in. and at a temp. of 540–815° for further formation of liquid hydrocarbons. 7

Recovery of gasoline hydrocarbons from gaseous mixtures such as those from oil cracking. David G. Brandt (to Power Patents Co.). U. S. 2,169,959, Aug. 15. An arrangement of app. is described, and a process in which the gases are passed through an absorption tower in countercurrent contact with an absorption medium such as a hydrocarbon oil and which involves passing the resulting rich absorption medium contg. the desired hydrocarbons and some lower-boiling undesired hydrocarbons from the absorption tower into a stabilizer, removing all of the undesired low-boiling hydrocarbons from the upper part of the stabilizer in vapor form and subjecting them to the absorbing action of an absorption oil while the removed hydrocarbon vapors and oil are passed in contact through a cooling zone, and thereafter the resulting cooled mixt. of absorption oil and absorbed lower-boiling hydrocarbons is introduced into the absorption tower as the absorption medium for recovering the desired hydrocarbons from the gases introduced thereinto. 9

Gasoline and fuel oil. John J. Downey and Wm. W. Murray (to Sinclair Refining Co.). U. S. 2,170,795, Aug. 29. An arrangement of app. is described, and a process for the manuf. of gasoline and fuel oil from asphaltic petroleum stocks contg. a high-boiling wax-bearing fraction of the type occurring in Calif. which comprises heating a stream of distillate oil to a high cracking temp. under superatm. pressure and controlling the temp., temp. gradient, pressure and time during the heating to prevent substantial formation of C therein, reducing the pressure on the hot oil products of the heating and bringing them into direct heat-exchange relationship with the asphaltic stock contg. the high-boiling wax-bearing fraction in a vapor-sepg. receptacle without prior heating of the asphaltic stock to a temp. at which substantial decompn. occurs, taking off from the receptacle a residual stock mixt. including the high-boiling wax-bearing fraction and a vapor mixt. including gas oil and gasoline; vaporizing the high-boiling wax-bearing fraction from this residual stock mixt. without substantial decompn. by the contained heat of the oil in an evaporator maintained under a pressure lower than that maintained in the receptacle, and condensing this high-boiling wax-bearing fraction and supplying it to the heating. 1

Apparatus for dispensing liquids such as gasoline from storage tanks. Warren H. De Lancey (to Gilbert & Barker Mfg. Co.). U. S. 2,171,687, Sept. 5. Various structural and operative details.

Hydrocarbon products by thermal conversion of materials such as gas-oil vapors. Mathias Pier, Walter Simon, Rudolf Becker and Fritz Stoewener (to Standard-I. G. Co.). U. S. 2,170,976, Aug. 29. Thermal conversions such as the production of gasoline hydrocarbons from gas-oil vapors are effected in the presence of a catalyst comprising a bleaching earth which can only be brought to swelling by treatment for at least 5 hrs. with a swelling agent such as water at about 100° and which has been subjected to such swelling. 4

Vapor-phase filtration of hydrocarbon vapors. Malcolm P. Youker (to Gray Processes Corp.). U. S. 2,170,180, Aug. 22. App. and various operative details are described for treating hydrocarbon vapors such as gasoline vapors to polymerize and filter out gum-forming and other objectionable constituents, with use of a fuller's earth filter. 5

Catalytic dehydrogenation of hydrocarbons. Alexis Voorhies, Jr. (to Standard Oil Development Co.). U. S. 2,170,437, Aug. 22. An app. is described, and a process for the catalytic dehydrogenation of a hydrocarbon, which involves passing the hydrocarbon through an annular chamber packed with a dehydrogenation catalyst, passing a fluid heating medium over the exterior of the annular chamber in heat-exchange relation therewith in a direction concurrent with the flow of reaction material therethrough whereby a hot zone is established in the reaction space, and then passing the fluid heating medium through the interior of the annular chamber in heat-exchange relation therewith in a direction countercurrent to the flow of reaction material therethrough, and maintaining indirect heat-exchange relation between the countercurrent flowing heating medium and the hydrocarbon for a substantial portion of the travel of the latter before it reaches the hot zone. 6

Purifying still residues of light-oil distillation. Frank W. Corkery (to Pennsylvania Industrial Chemical Corp.). U. S. 2,172,437, Sept. 12. Still residues resultant from the treatment and distn. of light oil derived from the by-product coking of coal which contain metallic sulfonates formed by acid purification and alk. neutralization in the light oil prior to distn. are purified by pptg. sulfonates from the still residue by agitating the still residue with low-boiling aliphatic hydrocarbon, wetting the ppt. by agitating the mixt. with water before the sulfonate ppt. coagulates, effecting stratification of the mixt. and settling of the ppt. expedited by injection of live steam into the mixt. to form a water layer contg. the sulfonates and a hydrocarbon layer contg. the other still residue ingredients in soln., sepg. the layer of still residue solu. and the sulfonate-contg. water layer, and by distn. recovering the still residue from soln. Cf. *C. A.* **33**, 1127[1,2,5]. 8

Apparatus for removing coke deposits from oil-conversion drums, etc. Geo. J. Langmyhr (to Standard Oil

Development Co.). U. S. 2,170,660, Aug. 22. Various structural, mech. and operative details.

Formation tester for oil wells. Christian Iden. U. S. 2,171,000, Aug. 29. Various structural, mech. and operative details.

Treating inorganic mineral slimes in oil wells. Abraham M. Herbsman (to Industrial Patents, Ltd.). U. S. 2,172,083, Sept. 5. An acid or alk. aq. suspension of a sulfonated glyceride such as a sulfonated fish oil or sulforated castor oil is introduced into that portion of a well in which there are accumulations of slime to be removed.

Handling cement slurry in oil and gas wells or the like. Arthur L. Armentrout and Ray Gudie (to Baggah Corp.). U. S. 2,171,840, Sept. 5. Various details of app. and operation, involving use of an elec. resistance device and depth indicator for detg. the position of slurry in a well bore.

Acidizing oil and gas wells in limestone formations. Paul G. Shelley (to Dow Chemical Co.). U. S. 2,171,011, Aug. 29. Aq. HCl is introduced in the presence of a relatively small proportion of a furan such as furfural, furoic acid or furfuryl alc., which serves as a retarder permitting deeper penetration of the acid.

Filter suitable for use with engine fuel oils. Thomas C. Makins (to Ruston & Hornsby, Ltd.). U. S. 2,171,004, Aug. 29. Various structural details.

Lubricating oil. Robert C. Cantelo (to Sinclair Refining Co.). U. S. 2,171,781, Sept. 5. A lubricating oil such as a hydrocarbon motor oil is rendered resistant to sludge formation and is given a reduced pour point by the addn. of about 0.5 3.0% of a metallic salt of erucic acid such as the Al salt.

Lubricating oil. Alfred Henriksen and Bert H. Lincoln (to Lubri-Zol Development Corp.). U. S. 2,172,382, Sept. 12. A lubricating oil of relatively low pour point and high film strength comprises a hydrocarbon oil such as one of 350 viscosity together with a small proportion (suitably about 1%) of a halogenated synthetic hydrocarbon oil obtained by halogenating (as by the action of Cl) to the extent of 5-20%, the condensation product obtained by the addn. of a halogenated wax such as chlorinated paraffin to a mixt. of an aromatic compd. such as naphthalene and a catalyst such as $AlCl_3$.

Refining lubricating oils. Ferdinand W. Breth (to L. Sonneborn Sons, Inc.). U. S. 2,170,628, Aug. 22. A petroleum lubricating oil fraction is brought into contact, at a temp. of about 40 150°, with bauxite activated by heating to about 315–870° and of about 30–60-mesh particle size, derived from bauxite ore having at least 20% of water of constitution and capable of removing asphaltic matter forming constituents to the amt. of at least 3% the quantity of the oil in the time of contact allowed.

Mineral lubricating oil. Arthur B. Brown and Fred F. Diwoky (to Standard Oil Co. of Ind.). U. S. 2,171,646, Sept. 5. A process for producing lubricating oil having a high viscosity index and a low true color from a mineral oil contg. naphthenic and paraffinic constituents involves extracting the mineral oil with an admixture of solvents selected from the group consisting of 60 to 40% chloroaniline and 40 to 60% cresylic acid, 85 to 40% chloroaniline and 15 to 60% of phenol, 60 to 40% of chloropnene and 40 to 60% of cresylic acid, to form two liquid layers, sepg. said layers and removing the solvents from each of the layers. Cf. *C. A.* **33**, 2325[5].

Hydrocarbon lubricating oils. Constantin Skrepinsky (to Standard Oil Development Co.). U. S. 2,170,626, Aug. 22. For producing a stable lubricating oil, a lubricating oil distillate is treated with a gas contg. free O about 5–7 cu. ft. for every 300 g. of oil per hr. at a temp. of about 205–232° for about 3–4 hrs., then treated with 1–30% H_2SO_4, and the acid sludge formed is sepd.

Sulfurized lubricating oil. Bert H. Lincoln and Waldo L. Steiner (to Continental Oil Co.). U. S. 2,172,285, Sept. 5. A lubricant which is corrosive to the Cu strip test, but which is suitable for use under extreme pressures, comprises a hydrocarbon oil together with about 1–4% of a base such as may be prepd. by sulfurizing unsatd. fat acid obtained from wood oil.

Lubricating oils from conversion products of the hydrogenation of carbon monoxide. Herbert Goethel and Heinrich Tramm. U. S. 2,172,441, Sept. 12. An arrangement of app. is described, and a method which involves subjecting the fractions, which are liquid at room temp., boil above 150° and comprise a substantial portion boiling closely above 150°, of hydrocarbon mixts. obtained in the catalytic conversion of mixts. of CO and H to a cracking treatment such as to yield a mixt. of hydrocarbons having a high content of unsatd. hydrocarbons, and subsequently subjecting this mixt. to polymerization in the presence of a catalyst.

Contact filtration of viscous lubricating oils for decolorization. Claude F. Tears (to Petroleum Processes Corp.). U. S. 2,171,377, Aug. 29. An arrangement of app. is described, and a process of treating lubricating oil, which comprises dissolving lubricating oil in a liquefied normally gaseous hydrocarbon solvent under pressure sufficient to maintain the solvent in the liquid state, heating and bringing the soln. into contact with adsorbent clay at a temp. in excess of 50° under pressure sufficient to maintain the heated solvent in the liquid state, sepg. the soln. from the clay under pressure sufficient to maintain the solvent in the liquid state and sepg. the treated oil from the solvent. Liquefied C_3H_8 may be used as the solvent.

Apparatus for testing the "gripping" point of lubricating oils. Charles C. Curtis (to Halstead Products Co.) U. S. 2,171,026, Aug. 29. Various structural, mech. and operative details.

Lubricant Armin J. Kraus (to Richards Chemical Works, Inc.). U. S. 2,169,918, Aug. 15. A highly viscous and stable lubricant suitable for lubricating gears, etc., comprises the product of polymerizing, by means of a catalyst consisting of a soln. of raw rubber in hepta and octa naphthenic acids, a readily sulfurizable mineral wax present in an asphalt base crude oil or a vegetable or animal oil or fat in the presence of a hydrocarbon material such as a naphthenic sludge, contg. naphthenic acids and capable of being polymerized without previous sulfurization.

Extreme-pressure lubricants. Clarence M. Loane and Bernard H. Shoemaker (to Standard Oil Co. of Ind.) U. S. 2,169,700, Aug. 15. A mineral lubricating oil has mixed with it about 10% or less of dodecene dithiocyanate or other org. compd. of the general formula $R(Y)n$ in which R is a substituent aliphatic or aromatic group or a metal, Y is a thiocyano or isothiocyano radical, and n is greater than 1.

Lubricant for gears. Gerald M. Fisher (to Socony-Vacuum Oil Co.). U. S. 2,170,495, Aug. 22. A heavy petroleum residuum is used with 5-20% of the resin remaining after distg. acid-treated and neutralized cracked petroleum distillate, such resin being hard and brittle, of a black color, sol. in heated petroleum oils and having an aromatic odor and the property of imparting adhesiveness to petroleum lubricants.

Voltolized sperm oil, etc., for use as a lubricant or for other purposes. Robert P. Russell (to Standard Oil Development Co.). U. S. 2,170,665, Aug. 22. By subjection of materials such as those contg. liquid wax ester components of sperm oil or spermaceti to a silent elec. discharge, a highly polymerized product is produced which may be used alone or in various mixts. as a lubricant or in coating or plastic compns., etc. The product may be subjected to hydrogenation, heat-treatment with reagents such as $AlCl_3$, BF_3, H_2SO_4 or alkali, and may be refined with clay, charcoal, acid, etc., and free acidic or hydroxyl groups may be esterified or otherwise neutralized. Products of extremely high mol. wt. may be pptd. or extd, from the voltolized product by diln. with solvents such as propane, *sec*-Bu alc., MeOH, acetone or CCl_4, with or without refrigeration or filtration.

Bituminous emulsions. Woodall-Duckham (1920) Ltd. and Edwin Arnold. Brit. 506,300, May 25, 1939. Addn. to 465,589 (*C. A.* **31**, 8153[9]). In the process of 465,589, wherein a H_2O-in-oil emulsion is made from the whole of the tar, pitch or bitumen, etc., and a part of the H_2O and an emulsifying agent, and this emulsion is then reversed by dispersion in concd. aq. solns. of an emulsifying agent,

the emulsifying agent used for the prepn. of the H_2O-in-oil emulsion consists of a soln. contg. farinaceous matter, e. g., starch, and an alkali or alk. salt, e. g., NaOH, Na_3PO_4, or a mixt. of such a soln. with an alkali alginate, and the emulsifying agent used for reversing the emulsion consists of an alkali-sol. protein and a small amt. of free alkali together with either an alk. farinaceous soln. or a mixt. of such a soln. and an alkali alginate. CH_2O may be added as a preservative.

Alkaline bituminous emulsions suitable for brushing or 2 **troweling.** Claude L. McKesson (to American Bitumuls Co.). U. S. 2,170,152, Aug. 22. A bitumen is dispersed in an aq. alk. soln. and a primary emulsifying agent is formed at the interface of the dispersed bitumen and the alk. soln. by reaction of the alkali in the soln. with acidic constituents naturally present in the bitumen, and a stabilizer is formed by the addn. of "calcium casein" to the soln., and the emulsion is neutralized with the acidic decompn. products of milk sugars to bring it to a pH of about 7.5–9.5.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

The network structure of cellulose. O. Kratky. *Silk and Rayon* **13**, 571–2, 634, 638(1939); cf. *C. A.* **33**, 6041[5]. — 3 The network structure of cellulose is considered to be made up of continuous chains of micelles connected by transverse micelles. During deformation, the entire system behaves like a single chain, especially if the proportion of the latter is small. The relative amts. of the crystd. and amorphous components depend on the history of the fiber. Native cellulose is practically all cryst.; a regenerated cellulose filament made from xanthate soln. may be largely amorphous. Soaking fibers in a gold chloride soln. and 4 exposing them to ultraviolet light result in filling the hollow spaces in the fibers with reduced gold. X-ray investigations of such fibers indicate an area of 50 to 70 A. in thickness between which there are narrow hollow spaces. The relation between the mech. properties and the degree of orientation is briefly discussed. Milton Harris

The ontogenesis and chemical structure of the vegetable cell wall. Kurt Hess, Wilhelm Weigin, Heinz Kiessig, Werner Engel and W. Philippoff. *Naturwissenschaften* **27**, 622–8(1939). —A review of development and structure of cotton fibers, differences between the phases of length growth and thickness growth, the change of cellulose from unordered form to regular mol. arrangement as found by x-ray and the presence of waxy material in the young fiber. The qualities of the primary and secondary wall materials 5 are compared in some detail. Whereas in the primary stage (length growth) waxes, phosphatides, protein, etc., 6 are formed in the walls, the second stage is primarily one of formation of cellulose lattice. The primary cellulose, present in small amts., is not in lattice form owing to the presence of the admixts.; removal of the latter spontaneously causes change to lattice form (x-ray, double refraction, swelling and viscosity evidence).

B. J. C. van der Hoeven

Björkman numbers of bleached cellulose. O. P. Golova and A. A. Metsler. *Bumazhnaya Prom.* **17**, 24–6 7 (1939). The Bjorkman no. is practically not affected by the pitch content in the cellulose, but it does vary with the degree of delignization of ordinary tech. cellulose. The lignin content in standard viscose cellulose varies from 0.14 to 0.39% when detd. in previously extd. cellulose by the method of Golova and Katz (cf. *C. A.* **29**, 6755[4]). In the Schwalbe and Becker method it varies from 0.97 to 1.2% without previous extn. The Björkman no. for viscose cellulose varied from 5.8 to 9.8. No conversion factor was found to relate the Bjorkman no. to lignin content as detd. by H_2SO_4. An increase in Bjorkman no. above 10–12 produced difficulties in converting the cellulose to viscose. The method of detg. the Bjorkman no. is given. B. Z. Kamich

Xanthation of cellulose in liquid ammonia. Philip C. Scherer, Jr., Lenard P. Gotsch, *et al. Bull. Virginia Polytech. Inst., Eng. Expt. Sta. Series Bull.* No. 39, 3–21 9 (1939); cf. *C. A.* **25**, 3826.—Cellulose xanthates sol. in H_2O were prepd. from tri-Na cellulosates and CS_2 in liquid NH_3 (I). Na halides accelerated the reaction between Na and cellulose in I. $NaNO_3$ accelerated the reaction between Na cellulosate and CS_2 in I. In the presence of I xanthates with a low degree of xanthation were obtained which decreased with further reaction, probably owing to the formation of ammono acid by-products with the solvent. Xanthation in the absence of I but in the presence of a small amt. of H_2O as catalyst led to the formation of di- and tri-xanthates after prolonged reaction. M. P.

The fast-growing rayon industry chooses the South for plant extensions. Reginald Trautschold. *Southern Power and Ind.* **57**, No. 11, 30–40(1939).—History and statistics are given for the Southern rayon industry, together with descriptions of the process, and flow sheets of the viscose, acetate and cuprammonium processes. In the manuf. of acetate rayon, somewhat less than a lb. of purified cotton linters is required per lb. of rayon, and in the viscose process somewhat more than a lb. of wood pulp; cotton linters are also used in the cuprammonium process. Chem. requirements are discussed. Av. requirements per lb. of rayon for steam are 46 lb., water 100–1000 gals. and electricity an av. of 2.5 kw.-hrs. The locations of the principal plants are given. R. W. Ryan

Safe practice in the viscose rayon industry. Wm. H Chesnut. *Ind. Eng. Chem., News Ed.* **17**, 658–9(1939). — A discussion of methods for ventilation, and control of toxic gases (CS_2 and H_2S) incident to the manuf. of rayon. Places in the manuf. operation where such hazards occur are pointed out and measures required to overcome these hazards are outlined. C. E. Curran

Determination and detection of viscose impurities. Ernst Kuhnel. *Kunstseide u. Zellwolle* **21**, 369–74(1939). —The detn. for routine testing is made by filtering under standard conditions a kg. of viscose dild. first with 500 cc. 5% NaOH and then gradually with 8.5 l. H_2O. A fine screen of Ni wire placed under the filter paper increased filtration speed. Before filtration the paper on the funnel was treated with 250 cc. 1% NaOH to swell the fibers and reduce the size of the pores. After the residue on the filter was washed several times with water it was washed into a beaker with H_2O and centrifuged in 4 portions. The clear liquid was decanted, the residues were combined and again centrifuged in a 100-cc. tube with the addn. of 15 cc. 0.5% rosaniline sulfate. The red-colored residue was transferred with H_2O and centrifuged again in a 15-cc. tube from which its vol. can be read accurately. This figure and the time of filtration give a valuable indication of the behavior of the batch in the plant. The impurities can then be detected microscopically. Mark Plunguian

Digestion with forced circulation at the Syas'sk plant. 8 I. A. Nagrodskii. *Bumazhnaya Prom.* **17**, 10–16(1939); cf. *C. A.* **33**, 5653[8].—By using forced circulation in the digestion operations in accordance with the Lurgi method improved results were obtained at the Syas'sk plant. At the usual density the cellulose was clearer and of somewhat better quality, and the waste was less. The digestion was reduced by 45 min. by increasing the temp. during impregnation to 110–114° and the final temp. to 148°. The SO_2 content in the lye was increased by about 0.5% and the rate of its decrease was less rapid. By using a specially designed thickener with the Lurgi app. the capacity of the digestion tanks was increased by 9%. Operating data are tabulated and graphed. B. Z. Kamich

Pulp woods of Manchoukuo. V. Chemical analysis and cooking experiments of Larix dahurica Turcz. Masuzo Sikata, Motoo Yamane and Hanzyutu Kin. *J. Agr. Chem. Soc. Japan* **15**, 542–6, *Bull. Agr. Chem. Soc. Japan* **15**, 98–101(1939)(in English); cf. *C. A.* **33**, 6044[4].—The

fiber length of the wood of *Larix dahurica* Turcz. was mainly 2.0–4.5 mm. An example of the analysis of the wood was: alc.-benzene ext. 3.70, cold-H_2O ext. 20.22, hot-H_2O ext. 21.31, 1% NaOH ext. 29.61, galactan 8.93, mannan 5.77, pentosan 11.78, hemicellulose 26.48, lignin 25.96, total cellulose 50.92, α-cellulose 37.12, β-cellulose 3.68, γ-cellulose 10.12, N 0.22, ash 0.35 and CH_3O 4.58%. The pulp was prepd. by cooking with Ca bisulfite. The bleached pulp contained α-cellulose 89.53–92.08, pentosan 0.65–3.40, ash 0.11–0.24 and Cu no. 0.50–1.17%. It may be used as the rayon pulp. Y. Kihara

Pulping of "anabiong" by the use of aqueous and alcoholic nitric acid. Mamerto Cruz, Jr., and Lilly Gomez. *Univ. Philippines Nat. and Applied Sci Bull.* **7**, 25–8(1939). —"Anabiong" (*Trema orientalis* (Linn.)), a Philippine wood species, was pulped by refluxing either sawdust or shavings with aq. or with alc. HNO_3, resp., and digesting the resultant product with dil. NaOH under low pressure. Unbleached pulp yields ranging from 27.6 to 35% were obtained under varying conditions. This pulp bleached easily and averaged about 74% α-cellulose. Exptl. papers were produced but no strength or other data regarding them are included. C. E. Curran

Manufacture of bagasse pulp. II. Digestion of bagasse with superheated water and bagasse pulp by soda process. Syosuke Tanaka and Muneo Koriyama. *J. Agr. Chem. Soc. Japan* **15**, 25–32(1939); cf. *C. A.* **33**, 2333[8].—When the bagasse was heated with H_2O under 5–6 atm. pressure for 2 hrs., the decrease of pentosan was most remarkable. When the bagasse was heated with 20% of NaOH under 3 atm. pressure, a superior quality of pulp was prepd. The pentosan content in the pulp was less than 4% and the Cu value less than 1%. There was no difference in the prepn. of pulp between the fresh bagasse and the one stored for half a year. Y. Kihara

Waste problems in the pulp and paper industry. Hervey J. Skinner. *Ind. Eng. Chem.* **31**, 1331–5(1939).—Effluents from paper deinking and strawboard require sedimentation. Sulfite wastes furnish SO_2, lignin, tanning exts., adhesives, cement "fixer," vanillin, etc., notably by the Howard process (*C. A.* **25**, 204; **28**, 4227[8]). The use of closed systems, supplemented by save-alls where necessary, has markedly reduced pollution load and may recover $100 worth of materials daily with a $10,000 investment. Foster Dee Snell

Utilization of rice straw. Nieves C. Portugal and Lilly Gomez. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 29–32(1939).—Rice straw was pulped by first treating with 1% soap soln. and bleaching with NaOCl, followed by digesting for 7 hrs. under 6–8 atm. pressure with a soln. contg. $NaHSO_3$, Na_2SO_3, NaOH and $ZnSO_4$. The resultant pulp, washed acid free, was boiled with 1% NaOH, washed and bleached. The unbleached yield was 37.9%, the bleached yield 26%, cellulose content 92%, pentosans 15–16%, α-cellulose content 91.5% (based on cellulose) and Cu no. 0.04–0.05. Papers were prepd. which had good tearing resistance. C. E. Curran

Controlling the properties of paper. A. R. Mathis. *Ind. chim. belge* **9**, 191–6, 254–8, 385–9, 429–35(1938); **10**, 94–7, 142–51, 188–94, 230–6, 355–6(1939).—After a brief outline of the manuf. of pulp and paper, the principal phys. and mech. tests and a few chem. tests to which paper is generally subjected are described. A. P.-C.

Strong acid. M. V. Muratov. *Bumazhnaya Prom.* **17**, 6–9(1939). - It is shown that the strengthening of acid with 8% SO_2 gas obtained from the pyrite furnaces in the acid department of a large cellulose paper plant is economically possible. B. Z. Hamich

---

Cottonseed and the Southern Regional Research Laboratory [studies on cotton cellulose] (Lynch) **27**. Decomp. and gas production of cornstalks under anaerobic conditions at 28° to 30° (Nelson, *et al.*) **16**. Water of constitution and water of hydration of animal and vegetable textile fibers (Baroni) **25**. Modified starch [for sizing paper] (U. S. pat. 2,171,796) **28**.

Goidànich, G., Borzina, G., Mezzetti, A., and Viviani, W.: Researches on the Staining and Preservation of Wood Pulp Destined for Paper Making Carried Out at the Royal Station of Plant Pathology, Rome. Rome: Tipografia del senato del Dott. G. Bardi. 513 pp.

Increasing the reactivity of cellulose to esterification reagents. Arnold Marschall (to E. I. du Pont de Nemours & Co.). U. S. 2,172,447, Sept. 12. Before esterification, cellulose such as that of wood pulp is pretreated with a soln. of NH_4ClO_4 or other salt of Na, K, Li, NH_4, amine or substituted amine with H_2SO_4, HCl, $HClO_4$ or H_3PO_4, and is dried to a moisture content of less than 12%, based on the dry wt. of the cellulose.

Cellulose ethers. Hans T. Clarke and Carl J. Malm (to Eastman Kodak Co.). U. S. 2,170,009, Aug. 22. For etherification, cellulose such as sulfite wood pulp is treated with aq. caustic alkali of at least 40% concn., some of the liquid is removed by pressure and the resulting mass is treated with a bath contg. an etherifying halide such as EtCl and a tert. alc. of 4–5 C atoms such as *tert*-BuOH as a solvent.

Cellulose ethers. Charles R. Fordyce and Joseph G. Stampfli (to Eastman Kodak Co.). U. S. 2,172,242, Sept. 5. Cellulose having a viscosity of at least 20 centipoises is esterified with a bath contg. an acetal such as ethylene formal so as to cause soln. of the ether formed, and the reaction is terminated before the reaction mixt. becomes acidic. Numerous examples with details are given.

Alkali-soluble cellulose ethers. Frank H. Reichel and Walter F. Hindry (to Sylvania Industrial Corp.). U. S. 2,172,109, Sept. 5. See Can. 378,431 (*C. A.* **33**, 2334[8]).

Mixed esters of cellulose containing unsaturated acid radicals. Charles R. Fordyce and Gordon D. Hiatt (to Eastman Kodak Co.). U. S. 2,170,016, Aug. 22. Mixed esters such as a cellulose acetate-oleate-stearate in which the oleyl-stearyl portion constitutes at least 25% and the oleyl 4–19% of the ester are suitable *for coating metal articles exposed to liquids* such as conductors in elec. transformers, articles which are submerged in sea water, etc., and may be prepd. by the reaction on cellulose acetate of stearyl chloride and oleyl chloride (several examples with details of the manuf. of similar prepns. being given).

Apparatus for drying cellulose acetate or other materials in a continuous operation. Clifford I. Haney (to Celanese Corp. of America). U. S. 2,171,652, Sept. 5. Various structural, mech. and operative details.

Drying solid particles, e. g., of cellulose acetate. British Celanese Ltd. Brit. 506,138, May 23, 1939. Solid material in particle form is dried first by mech. means, e. g., passage between rollers or centrifuging, to remove about half the H_2O and then by causing the material to pass through a confined space substantially filled by the material to which internal motion is imparted in the space to prevent the formation of channels or packing and passing a current of drying atm. across the path of the particles.

Plasticized regenerated cellulose suitable for filaments, sheets, films, etc. James F. Power and Ernest G. Almy (to Atlas Powder Co.). U. S. 2,172,406, Sept. 12. Flexibility and softness with widely varying humidity are imparted to regenerated cellulose by treatment with a sorbitol sirup contg. a relatively large proportion of sorbitol and substantial proportions of saccharitols, Na salts of hydroxycarboxylic acids contg. 4–6 C atoms, tetrahydric alcs. and monoanhydrohexitols.

Flexible films, tubes, etc., comprising cellulose or its derivatives, etc. John C. Woodhouse (to E. I. du Pont de Nemours & Co.). U. S. 2,170,845, Aug. 29. Products are formed of regenerated cellulose, glycol cellulose, cellulose glycolic acid, or lowly esterified or etherified cellulose derivs. contg. only one ether or ester group assocd. with several cellulose units, together with a softener such as diethanol formamide or other *N*-hydroxyalkyl amide having a b. p. of at least 175° at a pressure of 760 mm. Hg and a soly. of at least 5% in water at 60–70°.

Cellulose pellicles suitable for use as wrapping tissue. Wm. F. Underwood and Henry S. Rothrock (to E. I. du Pont de Nemours & Co.). U. S. 2,170,827, Aug. 29.

A water-sensitive film suitable for use as a wrapping tissue is formed from an aq. alk. cellulose soln. contg., as a deformation-restricting agent, a softening agent for the film comprising an org. compd. such as bis-ethoxyethyl malate in sufficient amt. to restrict the deformation of the film to a max. of 3.0.

Cellulose films suitable for use as wrapping tissue. Frederick M. Meigs (to E. I. du Pont de Nemours & Co.). U. S. 2,170,828, Aug. 29. A water-sensitive film suitable for use as a wrapping tissue is formed from an aq. alk. cellulose soln. and contains, as a deformation-restricting agent, a softening agent comprising diethylene glycol diethoxyacetate or other ester of a carboxylic acid contg. an ether group having a hygroscopicity of from 1 to 80, a b. p. of at least 135° at a pressure of 12 mm. Hg and a soly. of at least 1% in water at 20°, the ester being in sufficient proportion to restrict the deformation of the film to a max. of 3.0. U. S. 2,170,829 relates to like use of a carbamic acid ester such as butoxyethoxyethyl carbamate.

Apparatus for collecting rayon. Hendrik G. van der Waals and George E. J. Wiessing (to American Enka Corp.). U. S. 2,171,485, Aug. 29. An app. for collecting rayon comprises in combination a spinning pot which is circular in cross section and a member of generally similar cross section located within the pot and of substantially the same height as the inner wall thereof but unattached to the inner wall, the member being provided with recesses in its outer wall to form spaces between the inner wall of the pot and the corrugated member to facilitate simultaneously removal of the member with a thread package formed therein and having inwardly projecting portions of such conformation as to produce a corrugated, endless inner embracing wall, thereby causing the member to form corrugations of sufficient size and shape to introduce slack throughout all parts of the thread package wherein resistance to contraction would otherwise occur whereby when the package is formed and dried, uniform shrinkage is produced.

Apparatus for cutting bundles of continuous rayon filaments into staple lengths continuously with their production from a spinning machine. Vereinigte Glanzstoff Fabriken A.-G. Brit. 507,289, June 13, 1939.

Relief screen and top construction for pulp digesters. Paul Boehm. U. S. 2,172,120, Sept. 5. Various structural details.

Wood pulp. Paul Beyer and Otto Primavesi. Brit. 507,696, June 20, 1939. See Ger. 667,149 (*C. A.* **33**, 2336[4]).

Apparatus for removing water from wood pulp, cellulose, etc. Olaf Qviller (to Fiber Making Processes, Inc.). U. S. reissue 21,201, Sept. 5. A reissue of original patent No. 1,995,011 (*C. A.* **29**, 3158[5]).

Supplying pulp to papermaking machines. Bernard A. Malkin. Brit. 507,131, June 9, 1939. Pulp from a head box enters a pond-chamber supplied with compressed air through a pressure-regulating valve and flow beneath a slice plate with provision for sliding adjustment and for local flexure of the lip to the wire-cloth of the papermaking machine. The top of the pond-chamber is domed to eliminate dead corners and contains a rotary shower pipe to wash the walls and dil. the pulp passing to the wire-cloth.

Cylinder papermaking machines. Walmsleys (Bury) Ltd. and Herbert C. Randell. Brit. 506,844, June 6, 1939. In a machine for making paper or board, wherein pulp is fed over a dam from an inlet compartment, 1 or both walls of the compartment are adjustable to vary the width thereof, the cross section available to pulp approaching the cylinder gradually narrowing.

Suction apparatus for papermaking machines. Ernest Poirier. Brit. 507,797, June 21, 1939. In papermaking machines having a vacuum box in which the vacuum is created by the discharge of H_2O from the box through a drop leg, the degree of vacuum is automatically controlled by a throttle valve regulated by the fluids discharged from the box.

Forming wire support for papermaking machines. Earl E. Berry (to Beloit Iron Works). U. S. 2,170,109, Aug. 22. Various structural features.

Apparatus for processing a Fourdrinier wire for reducing knuckles. Andrew Parves. U. S. 2,170,308, Aug. 22. Various structural, mech. and operative details.

Stock-feed box for papermaking machines. Earl E. Berry (to Beloit Iron Works). U. S. 2,171,739, Sept. 5. Various structural, mech. and operative details.

Single-ply drier felt, with asbestos facing, for paper machines. Wm. A. Barrell (to Lawrence Duck Co.). U. S. 2,172,430, Sept. 12. Various structural and mfg. details.

Treating traveling webs of material such as paper and cellophane, with waxes, dyes or other coating or marking material. Wm. F. Grupe (to Chambon Corp.). U. S. 2,170,140, Aug. 22. Various structural and operative details of an app. having an intaglio cylinder immersed in a heated bath of the treating material and cooperating with an impression cylinder.

Applying sheet-rubber coverings to large rolls such as those of papermaking apparatus. Frank S. Bowker. U. S. 2,172,005, Sept. 5. Various details of app. and operation.

Laminated paper suitable for wrapping butter, etc. Van H. Wilshire (to Specialty Papers Co.). U. S. 2,171,775, Sept. 5. A container for butter or the like comprises a wrapping which is sealed substantially air-tight and formed of a single waterproof and greaseproof pliable composite paper sheet having an inner surface of vegetable parchment and an outer surface of paraffin-contg. opaque paper of light color bonded by a layer of paraffin to the vegetable parchment, the outer layer having a surface coating of paraffin, bonded to the other portions of the wrapping where in contact therewith.

Apparatus and process for making fiberboard, cardboard, pulp board, wallboard, etc. Fulide Products Corp. Brit. 506,656, June 1, 1939. Newsprint, etc., to be made into fiberboard, etc., is placed on conveyors, compressed and defibrinated by pickers, spread into a loosely piled layer, impregnated with binder and compressed.

Cardboard, wallboard, etc. Jean J. Montpellier. Brit. 506,624, June 1, 1939. Heat-insulating cardboard, etc., impervious to hot or cold liquids and gases, e. g., for packing-cases, for preserving foods or for roofing, etc., is made, flat or corrugated, by adding, e. g., to wood pulp, paper pulp, etc., in a pulping machine kieselguhr and $Al_2(SO_4)_3$ and, after, e. g., 10 min., dearin and Na_2CO_3 in hot H_2O, and, after, e. g., a further 10 min., Na silicate in H_2O.

24.—EXPLOSIVES AND EXPLOSIONS

STORM

Making explosives then and now. Ernst Berl. *Chem. & Met. Eng.* **46**, 608–14 (1939).—B. discusses the manuf. of explosives and use of substitute raw materials in Germany during the World War, and reviews the present situation in the U. S. regarding availability of raw materials for explosives and improved methods of manuf. C. G. S.

Sixty-third annual report of His Majesty's inspectors of explosives (for 1938). R. A. Thomas, H. E. Watts, N. Fawcett and C. W. Ede. *Home Office Rept.* (Brit.) 1939, 38 pp.; cf. *C. A.* **32**, 9499[9].—The report discusses accidents with explosives, petroleum products and compressed gasses. In the manuf. of explosives there were 103 accidents (7 killed, 56 injured), while 301 accidents (33 killed, 314 injured) occurred in the use of explosives. Petroleum spirits caused 46 accidents, acetylene 10. Three boys were killed and 4 injured by explosions caused by experimenting with sensitive mixts. contg. S or P, chlorates or nitrates, etc. The explosion of a mixer in the

manuf. of Gelignite killed 6 and injured 29. Twelve explosions occurred in operations connected with the loading of detonators. A marked increase occurred in the use of sheathed explosives in coal mines, the usual sheathing material being $NaHCO_3$. Details of many accidents are discussed, including several abroad. Appendixes to the report include statistical data on accidents. C. G. S.

Velocity of detonation of mixtures of solid explosives with nonexplosive liquids. Tadeusz Urbanski and Tadeusz Galas. *Compt. rend.* **209**, 558–60(1939); cf. *C. A.* **33**, 6047⁶.—When the velocity of detonation, V, of a solid explosive mixed with various liquids is plotted against the percentage of liquid, the curves are mainly of 2 kinds: (1) as for hexogen in glycerol, V first decreases to a min. for about 10% and then increases to a max. for about 30%, and then decreases again; and (2) as for hexogen in $COMe_2$, precisely the opposite of the first, rising to a max. for 10%, then decreasing, etc. The effect seems to depend solely on the coeff. of elasticity of, and therefore on the velocity of, sound (c) in, the added liquid. Thus if V_0 is the velocity of detonation of explosive + liquid, and V_s that of the same amt. of explosive per vol. without the liquid, $V_0 - V_s$ shows increase in velocity owing to replacement of interstitial air by liquid. The values of $V_0 - V_s$ for hexogen with and without 30% of $CHCl_3$, iso-Am alc., castor oil and glycerol are, resp., 1025, 1170, 1380 and 1635, while the velocities of sound in these liquids are 960, 1270, 1450 and 1920; penthrite with 20% of several liquids shows similar results. This apparently confirms the theory that $V = C + W$, where W is the velocity of the explosion wave. C. A. Silberrad

Cleaning-plant safety. J. R. O'Hanlon. *Safety Eng.* **78**, No. 1, 18–20(1939).—Hazards in the dry-cleaning plant and methods of preventing fires and explosions are discussed. Ann Nicholson Hird

Explosives. Walter Friederich (to Dynamit-A.-G., vorm. Alfred Nobel & Co.). U. S. 2,170,943, Aug. 29. Disruptive or brisant explosives which have good stability contain an org. tetrazyl azide such as methyl or ethyl or acetone tetrazyl azides.

Ammonium nitrate explosive. Milton H. Wahl (to E. I. du Pont de Nemours & Co.). U. S. 2,171,379, Aug. 29. A granular detonating explosive suitable *for use in mining coal* contains NH_4NO_3 intermingled with a binding agent and a sensitizing agent such as smokeless powder, and is agglomerated in the form of aggregates of loosely bound structure having a size such that substantially all of them are held on a 50-mesh screen.

Nitrostarch explosives. Jesse B. Bronstein, Jr. (to Trojan Powder Co.). U. S. 2,170,629, Aug. 22. Nitrostarch 25–75 is used with nitroisobutylglycerol trinitrate 75–25% in explosives, coating compns., etc.

Blasting charges. James Taylor and Imperial Chemical Industries Ltd. Brit. 507,328, June 13, 1939. The self-sustained decompn. of a confined blasting charge comprising an alkali metal nitrite and 1 or more NH_4 salts is initiated by introducing into contact with a portion of the mixt. a liquid acid medium of at least 1 molar normal concn. having a H-ion concn. less than that of a 0.5 N HCl soln. and sufficient to decomp. the alkali metal nitrite, the acidic medium being thus capable, as it is consumed, of maintaining in the presence of the charge a pH capable of decompg. the nitrite. The confined charge preferably consists of a stoichiometric mixt. in granular form of $NaNO_2$ and NH_4Cl. The mixt. may be stabilized with a small proportion of soda ash or MgO. The acidic medium is preferably capable of maintaining in the presence of the charge a pH not greater than 5.2 and not less than 1.0. Acids that may be used are HCl, HNO_3, glycolic or butyric acid, AcOH, mono- or trichloroacetic acid, H_2SO_4, H_2CrO_4, $(COOH)_2$, tartaric, maleic, succinic or citric acid or H_3PO_4. Other liquid acidic media include (1) acid salts, e. g., NaH_2PO_4, $NH_4H_2PO_4$, (2) buffer solns., e. g., mixts. of AcOH with AcONa, (3) hydrolyzable salts of acid reaction, e. g., $ZnCl_2$, $ZnSO_4$, $Al_2(SO_4)_3$, $CuSO_4$, $FeCl_3$, $Na_2Cr_2O_7$, $K_2Cr_2O_7$, $(NH_4)_2Cr_2O_7$. $MgCl_2$, $MgSO_4$, $MnSO_4$, $FeSO_4$ and $Pb(NO_3)_2$ are not effective.

Testing for inflammable gases, as in mines. Georg Keinath and Heinz Gruss (to Siemens & Halske A.-G.). U. S. 2,170,056, Aug. 22. The gas to be tested is passed continuously through a reaction chamber, an addnl. combustible such as naphthalene is evapd. to the satn. point into the test gas, and an ignition spark is intermittently supplied to the gas and vapor mixt. (various details of operation being described).

Device for discharging carbon dioxide gas or snow for fire-extinguishing purposes. Soc. anon. Sicli (formerly Soc. anon. des Extincteurs S. I. C. L. I.). Brit. 507,776, June 21, 1939.

Fire extinguishing. Concordia Elektrizitäts A.-G. and Hans Kuhn. Brit. 507,527, June 16, 1939. An extinguishing agent, particularly for burning metals, consists of an emulsion produced by intimately mixing 250 cc. of an oil free from soap with 100–200 g. of MeBr and ethylene bromide and then adding, at short intervals and with vigorous stirring, 200 g. of H_2O at a time until 700 g. has been added. The H_2O is added at 17°.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Estimation of pseudocumidine in acid dyes. C. F. Jablonski. *J. Assoc. Official Agr. Chem.* **22**, 771–2(1939).—The method (technique described in detail) consists essentially in extg. an alk. aq. soln. of the dye with $CHCl_3$, adding N H_2SO_4, evapg. the $CHCl_3$, cooling to 3–5°, adding 0.1 cc. of 10% $NaNO_2$, after 1 hr. pouring into a mixt. of 5 cc. of 1% aq. soln. of Schaeffer's salt (β-naphthol-6-sulfonate) and 45 cc. of 2 N Na_2CO_3, developing the color by heating 1 hr. on the steam bath at 70°, cooling, extg. with AmOH, dilg. the AmOH ext. with an equal vol. of gasoline or ligroin, extg. with H_2O, evapg. on the steam bath, dissolving the residue in 150 cc. of hot water, adding 10 g. Na bitartrate and titrating hot with standard $TiCl_3$ in the presence of a current of CO_2; 1 cc. 0.1 N $TiCl_3$ = 0.00338 g. pseudocumidine. The method gave a 91.1% recovery from Ponceau 3R to which a known amt. of pseudocumidine had been added. A. Papineau-Couture

Alizarin red and alizarates. R. Haller. *Bull. fédération intern. assoc. chim. textile couleur* **3**, 381(1938).—The brightness of alizarin red, applied by a mordanting process, is obtained by a prolonged treatment of the dyed goods in a bath at 105°F. to 107°F. contg. soap, K carbonate and tin salts. The fatty bodies are not only constituent parts of a lake but probably assure its fine dispersion. If the operations could be simplified alizarin red might again compete with the azoic colors. J. E. Smith

Nitrones. V. Certain acyldiphenylmethanes and the dyes therefrom. Fritz Kröhnke. *Ber.* **72B**, 1731–5(1939); cf. *C. A.* **33**, 4246⁷.—$(p\text{-}Me_2NC_6H_4)_2CHBz$ (I) (Staudinger, *C. A.* **8**, 686), faintly yellow, m. 168°, which is readily obtained (88% from $BzCHO.H_2O$ and 2.4 mols. $PhNMe_2$ heated 1 hr. in AcOH on the water bath, or, as the HBr salt, m. 227–8°, in 60% yield from phenacylpyridinium bromide, $PhNO$ and $PhNMe_2$ allowed to stand 10 days in alc. at 20° or in 51% yield from $BzCH{:}N(:O)Ph$, $C_5H_5N.HBr$ and $PhNMe_2$ after 24 hrs. at 20°), is of interest because compds. of this type may be regarded as the leuco bases of dyes differing from those of the Ph_3CH series only by the intercalation of the CO chromophore. The *dye* itself was obtained in the form of the *perchlorate*, a deep-blue powder with Cu surface luster and sol. in org. solvents with deep-blue colors, by treating I in aq. HCl at 2° with a freshly prepd. aq. suspension of PbO_2, adding Na_2SO_4, filtering from the $PbSO_4$

and adding $NaClO_4$; the colorless *carbinol base*, tablets losing 2% at 67°, m. 153 4°, dissolves in AcOH with bright-blue color deepening on standing. The *oxime* of I, yellowish, m. 160°, also yields a deep-blue dye with PbO_2. No phenylhydrazone could be obtained. *Dimethiodide*, from I and MeI in MeOH in pressure flasks on the water bath, tables losing 6% at 39° *in vacuo* (*diperchlorate*, m. 281° (decompn.)). *Benzoyltetraethyldiaminodiphenylmethane* (60% from BzCHO.H_2O and $PhNEt_2$), m. 111–12° (often seps. as a *hydrate*), gives a deep-blue color with PbO_2 and AcOH, is also obtained from phenacylpyridinium bromide, $PhNEt_2$ and PhNO allowed to stand 7 days in alc. *p-Methylbenzoyltetramethyldiaminodiphenylmethane*, m. 125°, obtained in 77% yield as the *HBr salt*, m. 228–9°, from *p*-$MeC_6H_4COCHO.H_2O$, $C_5H_5N.HBr$ and $PhNMe_2$ in alc. on the water bath or from *p*-methylphenacylpyridinium bromide, PhNO and $PhNMe_2$ in alc. *β-Naphthoylbis(p-dimethylaminophenyl)methane* (30% from naphthacylpyridinium bromide after 6 days in alc.), m. 132°. *p-Chlorobenzoyl analog* (61% from the pyridinium bromide, PhNO and $PhNMe_2$ heated 1 hr. in alc. on the water bath), yellowish, m. 148°. *Bis(p-dimethylaminophenyl)acetylthiophene* (46% from the pyridinium bromide after 1 hr. in boiling alc.), yellowish, m. 168–9°. *Trimethylacetylbis(p-dimethylaminophenyl)methane*, from the pyridinium bromide after 5 days in alc. at 20°, m. 158–9°. These dyes give, especially on silk, blue to blue-green, on tannated cotton, green shades but they are hardly faster than the corresponding Ph_3CH dyes; one disadvantage is the ease with which they are hydrolyzed. C. A. R.

The determination of quinaldine in certain coal-tar colors. W. H. King. *J. Assoc. Official Agr. Chem.* 22, 777–81(1939).—A method (technique described in detail) is proposed for the detn. of quinaldine (2-methylquinoline) in dyes (more particularly Quinoline Yellow WS and Quinoline Yellow SS). It is based on the sepn. of quinaldine from the colors by steam distn. followed by extn. from the concd. steam distillate and pptn. from acid soln. as a salt of phosphotungstic acid, which salt may be weighed before and after incineration at 500–50°. Wt. of ash × 0.152 = wt. of quinaldine. The reactions involved are: $3C_{10}H_9N + P_2O_5.24WO_3.xH_2O \rightarrow (C_{10}H_9N)_3PO_4.12WO_3 \rightarrow HPO_3.12WO_3$. The test appears to be sensitive, 1–2 mg. of quinaldine in 100 cc. giving a distinct ppt. with phosphotungstic acid. While com. lots of phosphotungstic acid appear to be remarkably uniform, it seems advisable that each analyst check his own batch of the acid before accepting the recommended factor for conversion of ash to quinaldine. A. P.-C.

Determination of 1,4-dihydroxyanthraquinone in D & C Green No. 5 (Alizarine cyanine green F). G. R. Clark. *J. Assoc. Official Agr. Chem.* 22, 784–5(1939).—The method (technique described in detail) consists essentially in sepg. the intermediate by continuous extn. with Et_2O from a slightly acid soln. of the dye, in turn removing it from the Et_2O by a 5% NaOH soln. (with which it forms a characteristic reddish blue color), and detg. colorimetrically by comparison with a standard soln. of the intermediate in 5% NaOH. A 94% recovery was obtained of a known quantity of the pure compd. added to the dye. A. Papineau-Couture

Effect of light on erythrosin and bromo acid (tetrabromofluorescein). O. L. Evenson. *J. Assoc. Official Agr. Chem.* 22, 773–7(1939).—Aq. solns. of erythrosin fade rapidly when exposed to direct sunlight, while the fading in 47.5% alc. is much slower. I appears to be liberated from the erythrosin mol. and Br from bromo acid by the action of light. Certain other dyes, in the presence of erythrosin, are destroyed, as a result of the action of light on the erythrosin present. A. Papineau-Couture

The dyeing of staple and spun viscose rayon. Charles B. Ordway. *Am. Dyestuff Reptr.* 28, No. 21 (*Proc. Am. Assoc. Textile Chem. Colorists*) P613-15(1939).—The differences in phys. properties of viscose rayon from those of cotton necessitate changes from the established dyeing procedures for cotton. Formanil colors are a range of dyestuffs which are dyed directly as substantive colors and after treated with CH_2O at 49°–60° for 20 min., rinsed hot and finished. W. H. Boynton

Some new dyeing and finishing auxiliaries containing nitrogen grease and water repellents. J. Wakelin. *Silk and Rayon* 13, 740–2(1939).—A description of recently discovered compds. characterized by the grouping —CH_2NH— which offer new possibilities in dyeing and finishing. Milton Harris

Printing metallic effects on acetate rayon cloth. Raffaele Sansone. *Rayon Textile Monthly* 20, 519–20(1939).—Very fine metallic imitations can be obtained on highly lustered acetate rayon cloths by the use of dyestuffs possessing a special affinity for this material, at a low cost and with a fairly simple printing process. Four practical paste formulas and a formula for each of 6 colors for lustrous acetate rayon fabrics are given. *Ibid.* 587,588. Means of obtaining zigzag line effects, scaly or extra glitter effects metallic ground effects, white effects and means of projecting metallic effects for the printing pastes are given. W. H. Boynton

Tintinol process. H. L. Siever. *Am. Dyestuff Reptr.* 28, No. 21, (*Proc. Am. Assoc. Textile Chem. Colorists*) P612-13(1939).—The dyestuffs employed in the tintinol process are selected with the idea of maintaining the max. fugitive value for viscose rayon, acetate rayon, cotton, wool and silk and mixts. of these fibers. The process which is outlined is claimed to be simple in operation, economical and efficient. W. H. Boynton

Physical testing in the textile industry. Erwin J. Saxl. *Am. Dyestuff Reptr.* 28, No. 21 (*Proc. Am. Assoc. Textile Chem. Colorists*) P615-18(1939).—The instruments discussed include: stiffness tester, compressometer single-fiber tester, tension meter, conditioning oven twist tester, waterproofing tester and porosity tester. W. H. B.

An account of a new textile fiber. Claude Diamond. *Silk and Rayon* 13, 538-42(1939).—The constitution and properties of casein fibers are discussed and compared with those of wool. Milton Harris

Guanaco fibers. A. C. Whitford. *Textile Research* 10, 22-3(1939).—Examn. of the nails and the coarse hairs in both guanaco and guanoquito shows no startling variations in the hairs from the ancient and the modern animals. The single const. difference lies in the no. of scales per in., which is somewhat less in the archaeological materials of each class. W. H. Boynton

Determination of artificial fibers (staple fiber) in mixtures containing cotton and other vegetable fibers. Arnaldo Cappelli and Riccardo Tuffi. *Ann. chim. applicata* 29, 231-40(1939).—The method consists in extg. the fibers in a boiling soln. of basic ZnClO, which dissolves the artificial fibers, leaving cotton or other vegetable fibers intact. A 60° Bé. soln. of ZnClO soln. is used (sp. gr. 1.835). A. W. Contieri

A preliminary investigation of the constituents of flax straw during water retting. Jean F. Couchman. *J. Council Sci. Ind. Research* 12, 183–90(1939).—Methods have been devised for the analysis of flax straw, and the detn. of pectin is described in detail. Samples of unretted, partly retted and fully retted straw were analyzed. One sample was removed from the ret at the end of 3 days, and the other sample at the end of 7 days, the temp. of the ret being 33°. The losses due to retting were 11 and 13.2%, resp., for the partly retted and fully retted samples. The total pectin content fell from 2.2 to 0.8% during the course of the ret, most of it being lost during the first 3 days. S. L. Gerhard

The use of hydrogen-ion and acidimetric determinations for indicating the end point of a bacterial ret. A. M. Munro and Jean F. Couchman. *J. Council Sci. Ind. Research* 12, 191–202(1939).—The pH value alone gives only a slight indication of the progress of the ret, and cannot be used as a criterion for the detn. of the end point. Electrometric titrations of the retting liquors from day to day make it possible to regulate the ret so as to produce a fiber of uniform quality. Retting to the point where the amt. of 0.2 *N* NaOH required to raise the initial pH value through one unit remains approx. const. after 24 hrs. produces a uniform fiber for different types of straw, and

may be taken as the earliest point at which a ret may be stopped to produce a shiveless fiber from the scutching machine. S. L. Gerhard

Water of constitution and water of hydration of animal and vegetable textile fibers. A. Baroni. *Gazz. chim. ital.* **69**, 435–43(1939).—Silk (I), wool (II), cotton (III) and rayon (IV) (Bemberg, viscose and acetate) were dehydrated completely by heating the I at 140° and the II, III and IV at 110°, the anhyd. fibers were hydrolyzed at 25° by an air current at various relative humidities and the proportions of water as a function of time were detd. The fibers were then immersed in water in a Dewar thermostat and the increases in temp. measured. This gave the *intermediate heats of swelling*. The *total heats of swelling* were detd. by hydrating in a calorimeter the anhyd. fibers in air satd. with water at 30°, and measuring the increases in temp. as a function of the water absorbed. The curves of total swelling were of the same general character as those of intermediate swelling. The curves of the heat of swelling of the animal fibers (I and II) were different from those of the vegetable fibers (III and IV), i. e., whereas the curves of III and IV had relatively continuous trends, the curves of I and II ascended sharply at 1.5 and 2% humidity, resp. This discontinuity is attributable to the presence in the animal fibers of 2 different types of water viz., water of constitution and water of hydration. Analogous results were obtained by tensimetric examn. of the dehydration of the various fibers. The heat of hydration of the dry fibers diminished rapidly with increase in the water content, and with a water content of 5% the heat of hydration was not over 1/3 of the total heat and with a water content of 10% this heat was only 0.1 of the total. Hence only the 1st part of the water absorbed is responsible for most of the heat evolved. This too indicates the existence of water of constitution and of simple hydration in the animal fibers. The energy expended in the formation of bonds for the water of constitution must represent a quantity of heat greater than that of simple hydration (cf. Champetier, *Bull. soc. chim.* [5], **5**, 577(1939)). C. C. Davis

Experiments on the preservation of ramie lines in sea water by impregnation with latex. B. Markus and J. W. van Dalfsen. *Arch. Rubbercultuur* **22**, 211-22(1938).—Ramie lines are more durable on immersion in water when vegetable-tanned initially than when impregnated with compounded latex alone. Lines treated both ways lose tanning ingredients more slowly, because of encasement in rubber, which retards the leaching action in proportion to its weight ratio. Fibers of the line ultimately putrefy when the tanning agent has all been lost by diffusion. The rubber sheath is still intact when this happens. D. E. Cable

Recent progress in the discovery of auxiliary products for textile industry use. Gordon-Abramov. *Rev. gén. mat. color.* **43**, 349–51(1939).—A review of paterts and some literature. Halsey E. Silliman

Technical evaluation of textile finishing treatments: flexibility and drape as measurable properties of fabric. Lelia J. Winn and Edward R. Schwarz. *Textile Research* **10**, 5–16(1939). W. H. Boynton

Quantitative microscopical analysis of mixed febrics. Hazel M. Fletcher. *Am. Dyestuff Reptr.* **28**, 624–6 (1939).—If one kind of fiber constitutes a very small percentage, microscopical analysis is often better than a chem. analysis. Blends of viscose, rayon and linen, or of viscose, rayon and cotton can be analyzed by dissolving the rayon in $Ca(SCN)_2$, but microscopical analysis is more rapid. Two methods of analyzing microscopically the usual blends of fibers are outlined. The percentage by vol. of each fiber can be expressed by the equation: percentage of fiber $A = 100n_aw_a/(n_aw_a + n_bw_b)$ and percentage by wt. of each can be expressed by the equation: percentage of fiber $A = 100\ n_aw_ag_a/(n_aw_ag_a + n_bw_bg_b)$, where n = no. of fibers, w = av. wt. of camera-lucida drawings of the cross sections and g = sp. gr. of the fiber. A table shows comparisons by chem. and microscopical analysis of several mixed fabrics. W. H. Boynton

Photochemical decomposition of the cystine in wool. Henry A. Rutherford and Milton Harris. *Textile Research* **10**, 17–21(1939).—Data confirm the hypothesis that the primary action of the radiation which results in a change in the state of the S and the corresponding lowering of the cystine content is independent of the moisture in the system. Moisture plays an important role in the secondary process, namely that involving the evolution of H_2S from the irradiated fibers. Decompn. of the cystine resulting from the thermal reactions under the conditions of expts. is negligible. Apparently the initial stage of the photochem. decompn. is an absorption of the radiant energy resulting in the dissocn. of the R–S–S–R group, probably into $R\text{–}S^+$ and $R\text{–}S^-$ ions, a reaction not catalyzed by moisture. A possible secondary reaction would be the reaction of the products of the primary process into water to form RSH and RSOH compds. The latter are unstable and generally decomp. with the liberation of H_2S. Also in *Am. Dyestuff Reptr.* **28**, 655–6, 678(1939); *J. Research Natl. Bur. Standards* **23**, 597–601(1939) (Research Paper No. 1255). W. H. B.

Calibration of silk-porosity meters. J. Teres and Philip Sharnoff. *Rayon Textile Monthly* **20**, 589–90 (1939).—The porosity meter with a rotameter developed at the National Bureau of Standards for calibration insures accurate measurement of porosity. W. H. B.

Sericin. V. Changes of silk proteins by heating with water. 2. Takeo Ito and Kozo Komori. *J. Agr. Chem. Soc. Japan* **15**, 300–4; *Bull. Agr. Chem. Soc. Japan* **15**, 46–8(1939)(in German); cf. *C. A.* **33**, 4793².—When sericin A was heated with H_2O, the viscosity of the soln. decreased. Sericin B dissolved partially by heating with H_2O, and the carbohydrate contents and the N distribution in the H_2O-insol. part were different from those of sericin B. It may be due to the formation of the H_2O-sol. substance in the degradation of sericin B micelle. The quantity of the sol. substance of the cocoon was remarkably affected by the temp. of extn. Y. Kihara

The determination by chemical means of hemp in textiles composed of mixed fibers containing cotton. I. Arnaldo Cappelli and Riccardo Tuffi. *Ann. chim. applicata* **29**, 225–31(1939).—Hemp is dissolved out of mixts. with cotton by means of an ammoniacal Cu soln. The soln. is prepd. by dissolving 10 g. $CuSO_4$ in 100 cc. H_2O. Then 14 cc. concd. NH_4OH is added, drop by drop, until the ppt. first formed is redissolved. One hundred and fifty cc. of 15% NaOH soln. is then added, and the ppt. filtered off. It is redissolved in 20 cc. concd. NH_4OH, and the filter washed with NH_4OH until 250 cc. has been added. This soln. contains 0.85% Cu. The cotton remains undissolved in this reagent. A. W. Contieri

Rot proofing of jute. H. A. Elkin and W. A. S. White. *Textile Mfr.* **65**, 394(1939).—Resistance to air exposure and microörganisms was the object of the tests. They consisted in impregnating the jute, washing with water for 24 hrs. to remove sol. substances, and burying the samples 6 in., folded crease down and, later, washing away the attached soil. The air exposure was for 1 month to sunlight during dry weather. Cu oleate, Cu and Zn naphthenates and Zn oleate were used and the extent of treatment was detd. by estg. the metal content of the proofed samples. Comparative tests on flax and cotton were also made. The percentage loss in strength after 3 weeks in soil at 85°F. was 71, 74, 100 on untreated jute, flax and cotton, resp. When treated with 0.8% Cu, jute lost 4%, flax 17% and cotton (0.1% Cu) 16%. When treated with Zn oleate 1.4%, jute lost 30% and flax 78%. It is noted that Zn compds. give greater antiseptic value to lignin fibers than to the purer ones. Tests on jute alone gave Cu oleate 1.4, 1.3, 1.1, 0.8% Cu a loss of 0, 0, 6, 4%, resp.; Zn oleate 1.4, 1.1, 0.9, 0.8% Zn, a loss of 39, 42, 48, 56%, resp.; Cu naphthenate 1.8, 0.8% Cu a loss of 0 and 3%; Zn naphthenate 1.1, 0.8% Zn, a loss of 0 and 0%; cuprammonium 1.8% Cu, loss 4%; creosote a loss of 10%; cutch chrome 0.3% Cr, loss 63%; paraffin, loss 71%. In rot proofing more than 1% is necessary, and Zn naphthenate is better than Zn oleate but this comparison is not noticeable in the Cu compds. However, a 0.6% Cu proprietary compn. gave complete protection. Jute

sunlight tests showed: 0.6% Cu oleate, loss 22%; Zn oleate 0.6% Zn, loss 18%; Cu naphthenate 1.3 and 0.8% Cu, loss 16 and 12%; Zn naphthenate 1.1 and 0.6% Zn, loss 13 and 14%; cutch chrome 0.3% Cr, loss 0%; untreated jute, loss 18%. In general, it could be said, the impregnations were of little avail, with the exception of the cutch chrome. Halsey E. Silliman

Progress in water treatment. Reginald Trautschold. *Rayon Textile Monthly* **20**, 597-600(1939). Na hexametaphosphate serves well in softening water for *textile use*. The removal of hardness and the control of alky. also are considered. W. H. Boynton

Dry-cleaning aids. John A. Stinson. *Laundry Dry Cleaning J. Can.* **19**, No. 10, 14, 16(1939).—Agents added to dry-cleaning solvent to improve its cleaning efficiency are classified as paste soaps, filter soaps or detergents. Paste soaps are alkali salts of fat acids which are not completely sol. in dry-cleaning solvent. Filter soaps are sol. and hence will pass through a filter. Other types of cleaning aids are called detergents. Good cleaning aids of any type should make the garments cleaner, leave a desirable finish on them, be free-rinsing, and should not interfere in the solvent-recovery system. A theoretical discussion is included. Charles R. Phillips

Treatment of liquid wastes from the textile industry. C. R. Hoover. *Ind. Eng. Chem.* **31**, 1352-8(1939).—A review with 18 references. G. G.

Regulations on coal-tar colors (Anon.) **12**. Capillary analysis of certified food dyes (Taub, Ortega y Canet) **12**. Cleaning-plant safety (O'Hanlon) **24**. Condensation products for rayon treatment (U. S. pat. 2,171,963) **13**.

Chwala, August: Textilhilfsmittel. Ihre Chemie, Kolloid-chemie und Anwendung. Vienna: J. Springer. 475 pp. M. 42; bound M. 45.

Azo dyes. Walter Kern and Richard Tobler (to Soc. pour l'ind. chim. à Bâle). U. S. 2,170,372, Aug. 22. Azo dyes which dye various colors fast to light are formed of components such as a 2,3-hydroxynaphthoic-3-aminopyrene reaction product and diazotized *o*-nitraniline. Numerous examples are given.

Complex metal compounds of azo dyes. Fritz Straub, Peter Pieth and Hermann Schneider (to Soc. pour l'ind. chim. à Bâle). U. S. 2,171,838, Sept. 5. Azo dyes such as the monoazo dye derived from 2-hydroxynaphthalene and 4-nitro-2-amino-1-hydroxynaphthalene-6-sulfonic acid are converted into complex metal compds., as by reaction with a Cr formate soln., which dye wool fast black tints. Several examples are given.

Acetate rayon dyes. W. W. Tatum and Imperial Chemical Industries Ltd. Brit. 506,526, May 30, 1939. H_2O-sol. salts of β-hydroxyethylaminoanthraquinone mono-esters of aliphatic and aromatic dicarboxylic acids having 3-12 C atoms are made by causing a β-hydroxyethylaminoanthraquinone, which may be substituted in the anthraquinone nucleus by Cl, Br, Me, NO_2, NH_2, alkylamino, arylamino, OH or alkoxy groups, to react with an anhydride of 1 of the said dicarboxylic acids, if desired in a liquid medium, e. g., pyridine, $PhNO_2$, and converting the product to a H_2O-sol. salt by soln. of the acid ester in an alk. soln. or by addn. of an alkali metal carbonate to the reactants. The products dye or print acetate rayon blue, red or violet shades. Among examples, (1) succinic anhydride is caused to react with 1-methylamino-4-β-hydroxyethylaminoanthraquinone, etc., and (2) maleic anhydride is caused to react with 2-chloro-1-amino-4-β-hydroxyethylaminoanthraquinone or 1,4-di-(β-hydroxyethylamino)-5,8-dihydroxyanthraquinone.

Increasing the solubility of dyes containing hydroxyl groups. Charles Graenacher, Franz Ackermann and Heinrich Bruengger (to Soc. pour l'ind. chim. à Bâle). U. S. 2,170,262, Aug. 22. Numerous examples are given of the improvement of the soly. of dyes such as azo dyes, which contain at least one hydroxyl group but no carboxyl or sulfonic groups, by treating the dyes, in the presence of pyridine, with acylating agents such as benzoic acid-3-sulfochloride, benzoic acid-3,5-disulfochloride and 1,3,6-naphthalenetrisulfonic acid chloride.

Condensation product from *p*-dichlorobenzene and sulfur trioxide. Willy Seel. U. S. 2,171,166, Aug. 29. A product which may be used as a *dye intermediate* or for *mothproofing wool*, etc., is obtained by treating *p*-dichlorobenzene with 30% oleum at a temp. of 15-25°, dilg. the reaction mass with cold water, and recovering the solid reaction product.

Fur dyeing. Edward Ohsman. U. S. 2,171,277, Aug. 29. Fur skins, for producing shadow effects, are immersed in a dye bath and simultaneously agitated and in part raised out of the bath successively and at intervals during the immersion.

Silk degumming and dyeing bath. Hugh H. Mosher (to Richards Chemical Works, Inc.). U. S. 2,169,881, Aug. 15. A silk degumming and dyeing bath contains soap, a boil-off oil, a degumming alk. salt, a direct dye and an oxidizing color stabilizer having protein coagulation properties sufficiently potent to convert solubilized sericin into insol. colloidal form but not substantially to prevent elimination of sericin from the material being treated, the color stabilizer being a compd. selected from the class consisting of Na or K dichromate, phosphotungstate, or phosphomolybdate or $CdSO_4$.

Apparatus for treating articles with fluids, as in dyeing or washing fabrics. George Kuhn. U. S. 2,171,449, Aug. 29. Various structural details.

Apparatus for decorticating and softening flax and like stalks. The Automatic Flax Production Units. Brit. 507,623, June 16, 1939.

Casein fibers. Stephen P. Gould and Earle O. Whittier (to the People for free use). U. S. 2,169,690, Aug. 15. For producing casein fibers of good strength and water resistance, fine streams of an alk. casein soln. are subjected to the action of an acid bath contg. a soln. of H_3PO_4 and an alk. earth phosphate such as mono-Ca phosphate. Cf. *C. A.* **33**, 9008[6].

Casein fibers. Theodoor Koch and Henricus A. van der Kroon (to American Enka Corp.). U. S. 2,169,955, Aug. 15. Casein fibers are rendered resistant to shrinkage and sticking in hot acid dye baths by treating the fibers with nitrous acid after they have been initially coagulated in an acid ppte. bath.

Polyisobutylene fiber. Peter J. Gaylor (to Standard Oil Development Co.). U. S. 2,170,439, Aug. 22. Fibers suitable for weaving into fabrics, and which have good stability and resistance to wear, comprise an odorless polyisobutylene of a mol. wt. of 100,000 to 250,000 and which may be produced by use of BF_3.

Apparatus and method for stapling threads or bundles of continuous fibers. Courtaulds Ltd. and Wm. Gower. Brit. 508,228, June 28, 1939.

Apparatus for testing the physical properties of fibrous substances, particularly the curling properties. Zellwolle-Arbeitsgemeinschaft G. m. b. H. Brit. 506,729, June 2, 1939.

Yarns and fabrics of mixed fibers. Camille Dreyfus and Wm. Whitehead (to Celanese Corp. of America). U. S. 2,172,439, Sept. 12. Yarns (which may also contain wool) contain at least 50% of a mixt. of fibers of the same org. deriv. of cellulose such as cellulose acetate at least 1.5 in. in length and of 2 different deniers, one of fine and the other of larger denier. Cf. *C. A.* **33**, 3610[2].

Treating yarns with liquid during winding. Universal Winding Co. Brit. 506,756, June 5, 1939. Yarn, fed at progressively varying linear speed during a transfer process, is uniformly treated with a liquid by being brought into contact with a surface whereon a film of the liquid is maintained, the thickness of the film being controlled by a wiper so as to be varied in accordance with the variation in the speed of the yarn.

Rayon yarns. John R. Caldwell (to Eastman Kodak Co.). U. S. 2,169,757, Aug. 15. A highly flexible yarn which is resistant to abrasion and adapted for use as warp in the manuf. of light fabrics comprises filaments each composed of a cellulose org. ester core such as one of cellu-

lose acetate and a size coating composes of a water-sol. cellulose org. acid ester such as cellulose acetate having the same dyeing characteristics as the material of the core and contg. a plasticizer, such as diethylene glycol, which penetrates into and is permanently occluded by the material of the core, so as to render the yarn highly flexible and to give it antistatic properties.

Esterified cellulose filaments, etc. Winfield W. Heckert (to E. I. du Pont de Nemours & Co.). U. S. 2,170,024, Aug. 22. For increasing the elasticity of cellulosic filaments, threads, fabrics or films, such as those formed of cotton or viscose rayon, the material is treated with a bifunctional esterification agent comprising a dianhydride or dichloride of a dicarboxylic acid such as a reaction product of phthalic or adipic acid and benzoyl chloride and the reaction is terminated when the desired increase in elasticity is obtained.

Treating artificial filaments, etc. Henry Dreyfus. U. S. 2,170,190, Aug. 22. For improving the extensibility of filaments, fibers, yarns, ribbons, etc., of materials such as cellulose acetate, they are subjected to saponn. under superatm. pressure with an aq. bath contg. 4-5% of a cyclohexylamine deriv. such as *N*-benzylcyclohexylamine.

Rotary drum apparatus for treating bobbins of yarn with liquid sprays. Robert B. Smith. (to Frank G. North, Inc.). U. S. 2,171,409, Aug. 29. Various structural and operative details.

Device for lateral stretching of webs of textile material. Max Hannig (to Vereinigte Faerbereien und Appretur A.-G.). U. S. 2,171,551, Sept. 5. Various structural and operative details.

Yarn-cheese core. Joseph O. Precourt. U. S. 2,171,890, Sept. 5. A core in the shape of a hollow open-sided cylinder is composed of spiral convolutions spaced a substantial distance apart and formed of a strip of vulcanized fiber having hardened outer surfaces resistant to heat and moisture when subjected for extended periods to the action of boiling dye liquor and a relatively less hard and impervious body portion between the hardened outer surfaces.

Viscose rayon. Walter H. Glover and Geo. S. Heaven (to American Viscose Corp.) U. S. 2,170,752, Aug. 22. About 1% or more of a petroleum product of high b. p. such as a petroleum jelly is used in viscose rayon, and serves to give a reduced luster.

Rayon. Walther Zetzsche, Johannes Giesen and Emmerich von Pongratz (to I. G. Farbenind. A.-G.). U. S. 2,171,324, Aug. 29. A rayon which has a matt luster similar to silk comprises regenerated cellulose contg. a catalytically hydrogenated liquid residue of the production of alc. by a catalytic process such as by reaction of CO and H (this residue comprising mixts. of unsatd. hydrocarbons with branched aliphatic C chains, branched chain lactones, branched chain higher alcs. and complicated org. compds. of unknown structure and b. 100-350°).

Silk treatment. Treat B. Johnson (to Textile Foundation). U. S. 2,171,241, Aug. 29. Acylation of silk fibroin is effected by use of a ketene (suitably at room temp.) to obtain a product which is suitable for dyeing and has good stability.

Ornamented fabric. Henry Dreyfus and Wm. A. Dickie (to Celanese Corp. of America). U. S. 2,171,626, Sept. 5. Ornamental effects are produced by introducing into a closely woven fabric unshrunk cellulose deriv. yarns such as those of cellulose acetate which extend in length by at least 30% when subjected to a finishing treatment in aq. medium, along with yarns which extend to a lesser degree when so treated, and subjecting the material to such a finishing treatment.

Pattern fabrics. Georges Heberlein and Ernst Weiss (to Heberlein Patent Corp.). U. S. 2,171,513, Aug. 29. A swelling agent or shrinking agent is used for treating a fabric contg. inactive formaldehyde cellulose fibers and active fibers woven in a pattern, the active fibers being natural vegetable fibers such as cotton which are active to the treating agent. Cf. *C. A.* **33**, 8036[6].

Pattern effects on fabrics containing nitrated and unnitrated fibers. Georges Heberlein and Georg Heberlein (to Heberlein Patent Corp.). U. S. 2,172,443, Sept. 12. A process of producing fabrics of a transparent character and with pattern effects consists in taking for treatment a fabric contg. unnitrated fibers and nitrated cellulosic fibers, decompg. and removing portions of the nitrated fibers according to a desired design, at least partially denitrating the remaining nitrated fibers, and subjecting the fabric to a transparentizing treatment of a character adapted for rendering natural cellulose fabrics more transparent, and for causing the ends of the yarn of denitrated fibers which collectively form the outlines of the pattern effects to be somewhat thickened, rendering the outlines more pronounced. Desired partial removal of the nitrated fibers may be effected by use of a NaOH paste printed on in a pattern. Cf. *C. A.* **33**, 8036[6].

Fixing cloth finishes. Hilton I. Jones and Llewellyn Jones. U. S. 2,171,475, Aug. 29. For affixing a finish on a textile material such as cloth in the bolt, it is immersed in an aq. bath contg. cornstarch 1-3 and stearate soap 2.5 7.5%, wrung to remove surplus soln., immersed in a 1-5% bath of rare earth acetates such as those of Ce, Th or La and again wrung, and dried.

Fabric-finishing apparatus. Alexander H. Gentle (to Celanese Corp. of America). U. S. 2,170,968, Aug. 29. Various structural and operative details of an app. suitable for finishing pile fabrics by glossing, etc., and treatment with a vapor such as steam.

Laminated fabrics suitable for articles such as collars, cuffs, which are repeatedly laundered. Gustave Klinkenstein (to Maas & Waldstein Co.). U. S. 2,171,505, Aug. 29. Layers of material are joined together by a thermoplastic adhesive, which will soften at a temp. of about 135°, comprising cellulose acetate or nitrate plasticized with about an equal amt. of methyl phthalate of ethyl glycolate. U. S. 2,171,506 relates to generally similar products contg. ethyl phthalate of ethyl glycolate.

Laminated cloth suitable for shirt collars or bosoms, etc. Harry W. Klinger (to Hercules Powder Co.). U. S. 2,170,416, Aug. 22. Articles such as collars are formed of a plurality of layers of cloth adhered by means of a bonding compn. including a cellulose acetopropionate, the cellulose ester constituting the major proportion of the compn. and being characterized by an analysis within the range of about 10% acetyl -34% propionyl to about 26% acetyl— 18% propionyl, a m. p. within the range of about 130° to about 220°, and a moisture absorption of not more than 5.5%, the article being resistant to the action of alk washing solns.

Apparatus for intertwisting strand material into cables, etc. Lester O. Reichelt (to Western Elec. Co.). U. S. 2,171,993, Sept. 5. Various details of an app. the speed of which is controlled in accord with the angular speed of twisting of the material under treatment.

Sizes for rayon. Jean Luria, Emile Luria and Charles Luria (to Luria Soc. à responsabilité limitée). Brit. 506,670, June 2, 1939. Rayon is sized with oxidation products of semidrying or nondrying oils, the oils having been oxidized to such a degree that they are resilient but capable of taking the shape of a vessel contg. them. The oil may be olive, colza, castor, cottonseed, arachis or coconut and may be oxidized by means of air, O or O_3, if desired in the presence of catalysts, e. g., salts of Mn, Co or Pb.

Sizes. L. J. G. Müller & Co. Brit. 507,744, June 20, 1939. Textile fibers or fabrics are sized by fresh or dried blood in aq. solns. The blood may be defibrinated. Known softening or wetting agents may be added.

Rendering textile materials water-repellent. Walther Kaase and Ernst Waltmann (to Heberlein Patent Corp.). U. S. 2,171,791, Sept. 5. A textile material such as one of wool, cotton or rayon is heated with an unsymmetric fatty-acid carbonic-acid ester anhydride such as a benzine soln. of unsym. stearic acid carbonic acid ethyl ester anhydride (the fatty acid radical having at least 10 C atoms and the carbonic acid ester having at least 2 C atoms) to volatilize the carbonic acid radical having the lower number of C atoms and to increase the water-repel-

lence of the textile material. Several examples with details are given.

Liquid treatments such as washing of materials such as rayon in cake form. Harry S. Drum and William C. Dodson (to Smith, Drum and Co.). U. S. 2,171,975, Sept. 5. Various details of app. and operation.

Carroting fur. Constantine F. Fabian (to Non-Mercuric Carrot Co.). U. S. 2,169,997, Aug. 22. Use is made of a soln. contg. as its carroting agent a compn. consisting of a volatile hydrolyzing acid selected from HNO_3, HCOOH and AcOH, and a volatile oxidizer selected from H_2O_2, org. peroxides and org. per acids, the hydrolyzing acid having a pH equiv. at least to that represented by a concn. of 11–12% of HNO_3 of approx. 63% tech. and the soln. being substantially free from non-volatile carroting agents.

26—PAINTS, VARNISHES AND LACQUERS

A. H. SABIN AND CARLTON H. ROSE

The Division of Paint and Varnish Chemistry. G. G. Sward. *Ind. Eng. Chem., News Ed.* **17**, 678(1939).—A brief history and description of this Division of the Am. Chem. Soc. E. J. C.

Traffic paint. Leroy Shuger. *Drugs Oils & Paints* **54**, 343–4, 346(1939).—A paper on the specifying, formulating and applying of traffic paints. The following are discussed: (1) essential requirements of a traffic paint—methods of test, (2) comparison of present State Highway specifications and compn., (3) road tests and durability, (4) use of auto colliminating units and (5) present methods used for applying the paint. Points discussed include: settling, consistency, drying time and visibility (day and night). W. H. Boynton

The paint and varnish industry. Pekka Kirjakka. *Teknillinen Aikakauslehti* **29**, 227–35(1939).—A review. S. A. Karjala

Formulation of ink specialties. Charles F. Mason. *Chem. Industries* **45**, 427–9(1939). E. H.

Petroleum naphthas and thinners in paint, varnish and lacquer from the naphtha manufacturers' viewpoint. R. D. Armsbury. *Drugs, Oils & Paints* **54**, 347–8(1939). Naphthas employed in paint, varnish and lacquer industries fall into 3 main classes: (1) straight-run naphtha products, (2) naphthas manufd. by the Edeleanu extn. process which employs liquid SO_2 as the extn. medium and (3) synthetic solvents. The last group is growing rapidly and includes acetone, diacetone alc., isopropyl ether, Me Et ketone, Me iso-Bu ketone, tertiary Bu alc., secondary Bu acetate, the cellosolves, Carbitols and certain high-boiling naphthas or solvents with b. ps. from 204° to 316° and contg. mixts. in considerable portions of hydrogenated naphthalenes and alkyl naphthalenes. Naphtha control tests include the distn. range test, and S or corrosion tests. Solvency power tests include: (1) kauri butanol value, (2) aniline cloud test, (3) blown linseed oil soly. ratio or blown soybean oil soly. ratio, (4) lacquer diln. ratio, (5) toluene-heptane no., (6) solvency of thinner or naphtha on especially selected varnish or synthetic resin base vehicle. W. H. Boynton

Liquid driers—their function, difficulties involved, improvements and methods of test. W. T. Pearce. *Am. Soc. Testing Materials, Bull.* No. 100, 31–2(1939). G. G.

The starch of immature linseed F. Robertson Dodd. *Analyst* **64**, 735(1939).—The starch content of mature linseed is negligible and when starch is found in linseed cake, it is usually taken as evidence of adulteration. Some pods grown in the wet summer of this year contained immature but fully grown seeds contg. starch granules indistinguishable from tapioca starch but a little smaller than those of sweet-potato starch. W. T. H.

Treating Al surfaces for painting (U. S. pat. 2,171,546) 9. Protective paint coatings on Al and its alloys (U. S. pat. 2,171,545) 9.

Paints. Herman B. Kipper. U. S. 2,171,851, Sept. 5. Liquid unsatd. petroleum hydrocarbons or their chlorinated derivs. are used with linseed oil, pigments, paint thinners and an NH_4 halide such as NH_4Cl, as a polymerizing catalyst, 1–20% of the wt. of the pigments used, for drying or polymerizing the paint oils to produce hardened coating films.

Proportional mixing scale (suitable for use in mixing paints or lacquers of different colors). Edward D. Holmes (to Sherwin-Williams Co.). U. S. 2,169,952, Aug. 15. Various details of a device suitable for use with paint cans.

Apparatus (utilizing a water spray) for cleaning air from paint spraying booths, etc. Henry C. Lambert and Squire E. Garnsey (to The De Vilbiss Co.). U. S. 2,171,574, Sept. 5. Various structural and operative details.

White titanium oxide pigment. Roy Dahlstrom (to National Lead Co.). U. S. 2,170,940, Aug. 29. For increasing its reflectance in the shorter wave lengths of the visible spectrum relative to its reflectance in the longer wave lengths of the visible spectrum, a white TiO_2 pigment contg. 0.0001–0.001% of W or Mo is exposed to the action of H at a temp. of about 900° for about 1–5 sec.

Composite titanium dioxide-calcium carbonate pigment. Louis E. Barton (to National Lead Co.). U. S. 2,170,800, Aug. 29. A previously prepd. TiO_2-$CaSO_4$ composite pigment is treated with an aq. soln. of a carbonate such as Na_2CO_3 which reacts to form a sol. sulfate and $CaCO_3$, and the pigment thus formed is sepd. from the resulting mother liquor.

Water printing inks. Hans Hadert (to Michle Printing Press and Mfg. Co.). U. S. 2,170,198, Aug. 22. A process for producing water printing inks consists in prepg. a soln. of water and a water-emulsifiable oil selected from a group consisting of sulfonated castor oil, sulfonated neat's-foot oil and sulfonated olein, prepg. a soln. of an alc.-sol. copal resin, alc. and a water-emulsifiable oil selected from the group mentioned, adding an alkali to the last-mentioned soln. in an amt. necessary to reduce the high acidity of the same, adding an org. base selected from the group consisting of monoethanolamine, diethanolamine and triethanolamine, mixing the solns. and adding to the varnish so produced water-insol. coloring matter.

Lacquer. Walter J. Clarke (to Bell Telephone Laboratories, Inc.). U. S. 2,170,187, Aug. 22. A perspiration-resistant lacquer is formed of volatile solvents together with nitrocellulose 52, alkyd resin 18, dibutyl phthalate 15 and an impalpable powder of silica gel 15 parts.

Lacquers and film-forming compositions containing nitrocellulose, etc. Ralph T. K. Cornwell (to Sylvania Industrial Corp.). U. S. 2,170,632, Aug. 22. A compn. for prepg. flexible transparent and nontacky coatings or films is prepd. with use of a cellulose deriv. such as nitrocellulose 30–70, with other ingredients such as paraffin or an animal or vegetable wax about 2–6, and a plasticizer such as an acetyl deriv. of *o*-benzoylbenzoic acid or other reaction product of a monocarboxylic acid of the benzophenone series with an aliphatic acid, suitable volatile solvents such as EtOAc, BuOAc and toluene.

Substituted biphenyl compositions suitable for plasticizing lacquer and varnish materials. Herbert J. Krase (to Monsanto Chemical Co.). U. S. 2,172,391, Sept. 12 A normally liquid product is used which consists of a mixt. of alkylated biphenyl derivs. having less than 6 C atoms in the alkyl groups obtained by the direct alkylation, in the presence of a Friedel-Crafts catalyst, of biphenyl, hydrogenated biphenyl, chlorinated biphenyls or brominated biphenyls with C_2H_4, C_3H_6 or other alkylating

agent from olefins, alcs. or alkyl halides having less than 6 C atoms in the mol.

Resins soluble in alcohol and suitable for lacquers. Werner Wolff and Karl Vierling (to I. G. Farbenind. A.-G.). U. S. 2,172,305, Sept. 5. Colophony or its resin acids are esterified with 2,2-dimethylol-1-butanol (suitably at 250–260° for 5 hrs.).

Refining rosin. Byron M. Vanderbilt (to Commercial Solvents Corp.). U. S. 2,170,956, Aug. 29. For refining a soln. of rosin in a solvent such as naphtha b. 97–123° is treated with a nitroparaffin, such as nitromethane or nitroethane, which is immiscible with the rosin solvent used and which is used in about 80% the vol. of such solvent, the nitroparaffin used forming a sep. phase with dissolved impurities removed from the rosin. Cf. *C. A.* **33**, 4806[7].

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Antioxidants and the autoxidation of fats. Autoxidation of oleic acid, methyl oleate, oleyl alcohol and *cis*-9-octadecene. F. E. Deatherage and H. A. Mattill. *Ind. Eng. Chem.* **31**, 1425–31(1939).—Peroxides, peracids, aldehydes and substituted ethylene oxides and combinations of these and H_2O are formed by autoxidation of the above fats The O consumption per mole of double bond destroyed is least for oleic acid and most for oleyl alc. Oxido derivs. are the main products of the process and are all of the same geometrical configuration and correspond to the high-melting dihydroxy isomeric deriv. of the original substrate. E. Scherubel

Crystallization of the pigment of flamingo fat. Carmela Manunta. *Helv. Chim. Acta* **22**, 1151–3(1939).—The deep-yellow fat of an African flamingo (probably *Phoenicopterus roseus*) was sapond. and the pigment extd. and adsorbed chromatographically on lime in the usual way. A new carotenoid pigment was finally isolated in red crystals. Names proposed are *phoenocopterin*, or, since it appears to be a xanthophyll, *phoenicoxanthin*. The spectral absorption curve was very similar to that of astacin except that the max. was at 487 mμ instead of 500 mμ. When mixed with astacin it was readily sepd. from the latter by chromatographic adsorption on lime. It is very sol. in C_6H_6, in which astacin is nearly insol., and very sol. in Et_2O, MeOH, petr. ether and $CHCl_3$. The solns. are yellow. Astacin was not present in the fat. L. E. Gilson

Addition (iodine) number of fats. N. Schoorl. *Pharm. Weekblad* **76**, 1295–7(1939).—Various methods for the detn. of I no. of oils were compared. The Winkler method (cf. *C. A.* **21**, 3103; **28**, 1299[7]) gives the most rapid absorption, especially when applied to cod-liver oil. Felix Saunders

How accurate must an official fat stability test be? Egbert Freyer. *Oil and Soap* **16**, 191–4(1939).—The results of 3 years' Comm. testing of coöperative samples by 11 labs. using the Swift Fat Stability Test are tabulated in 3 tables. Four of the participating labs. obtained consistently good results while 2 others failed to show agreement after 1 or 2 yrs.' experience with the test. In the light of the apparent shortcomings of the method, it is discussed from the standpoint of its suitability as an official method of the Society. The question is left unanswered. E. Scherubel

Method for measuring the color of fatty oils. Kokiti Osima and Tatuo Sugawara. *J. Agr. Chem. Soc. Japan* **15**, 653–8; *Bull. Agr. Chem. Soc. Japan* **15**, 110–11(1939) (in English).—The mixts. of $K_2Cr_2O_7$ and $CrK(SO_4)_2 \cdot 12H_2O$, K_2CrO_4 and $Co(NO_3)_2 \cdot 6H_2O$ were used as the standard colors, resp., for brown, yellow and red. These colors did not fade for a long time even under direct sunlight. The colors of the oils can be shown by the combination of these standards. Y. Kihara

Solidification-point curves of binary acid mixtures. I. Capric, lauric, myristic and palmitic. H. A. Schuette and H. A. Vogel. *Oil & Soap* **16**, 209–12(1939).—The solidification point and curves representing mixts. of pure capric-lauric, lauric-myristic and myristic-palmitic acids are recorded as data and in graphs. The practical value of the curves lies in the fact that they would serve as a means of establishing the presence of 2 acids in a mixt. of known mol. wt. By locating on the proper curve the observed solidification temp. of the mixt. of 2 fat acids which have been isolated from a naturally occurring fatty oil the mol. percentage compn. can be read off. E. Scherubel

Chromatographic separation of a mixture of palmitic, stearic and oleic acids. Carmela Manunta. *Helv. Chim. Acta* **22**, 1156–60(1939).—A mixt. of equal parts of the 3 acids was dissolved in petr. ether and percolated through a chromatographic column of dried $MgSO_4 \cdot {}^1/_2H_2O$. A nearly complete sepn. was obtained. The palmitic acid remained in the upper part of the column and the stearic acid in the lower part with a relatively barren zone between. The oleic acid was not adsorbed. Similar results were obtained with a column of franconite. L. E. Gilson

Methods of analysis of mixtures of oleic, linoleic and saturated esters and their application to highly purified methyl oleate and methyl linoleate. R. W. Riemenschneider and D. H. Wheeler. *Oil & Soap* **16**, 219–21 (1939).—Iodine nos. by the Hanus and Wijs methods and thiocyanogen nos. using various absorption periods were detd. on Me oleate and Me linoleate and on mixts. of these esters. It is concluded that I nos. by the Wijs method and 3-hr. thiocyanogen nos. are more satisfactory for Me linoleate and for mixts. contg. large amts. of this ester. Small amts. of higher satd. acids were detd. with a precision of about 0.1 unit percent by means of the Bertram procedure. A purified specimen of Me oleate contained about 0.2% of satd. ester by this method. E. S.

Note on the detection of myristic acid in alfalfa-seed oil. H. A. Schuette and H. A. Vogel. *Oil & Soap* **16**, 223 (1939).—Fractional distn. of the Me esters of the mixed satd. acids yielded a fraction having a mol. wt. suggesting a 2-component mixt. consisting of 65 mol. % myristic ester and 35 mol. % palmitic. The solidifying point of the mixt. was detd. to establish identity and found to be 40.45° which on reference to the binary acid solidifying-point curve for myristic-palmitic acids indicated a myristic acid content of either 64.3 or 80.5 mol. %. The former value is in agreement with that obtained by calcn. Thus acid is a minor constituent of alfalfa-seed oil, only 1.28% having been found. It has never been previously reported. E. Scherubel

Variation in free fatty acid within a seed sample. Proctor Thomson. *Oil & Soap* **16**, 221–3(1939); cf. *C. A.* **33**, 8883.—The A. O. C. S. seed samples for the 1938–39 season were analyzed by Edeler's method and the results on the 10 seed samples and the A. O. C. S collaborators are shown on a graph. There is a fairly close relationship between the scatter of the A. O. C. S. results and the scatter of the 10 seed results. The standard deviation of individual seed calcd. from the collaborators is greater in every case than when calcd. from samples of 10; and this indicates that the sampling of the sample itself is in need of attention. E. Scherubel

Preparation and properties of highly purified methyl oleate. D. H. Wheeler and R. W. Riemenschneider. *Oil & Soap* **16**, 207–9(1939).—Me oleate of high purity was prepd. by fractional distn. and low-temp. crystn. of the Me esters of the acids of olive oil. From the data gathered it is shown that the preliminary distn removed most of the satd. esters which were palmitic. This was followed by (1) removal of most of the linoleic ester by crystn. from acetone at 60°, (2) pptn. of the bulk of the satd. esters from acetone at 37° and removal by filtration, (3) further elimination of Me linoleate by 2 crystns. from

acetone at 60°, (4) fractional distn. *in vacuo* to remove small amts. of remaining Me palmitate, (5) 2 crystns. at 65° from redistd. petr. ether to remove last traces of linoleate. The purity of the final product was 99% or better and had the following properties: n_{20} 1.4522, d, 0.8739 and m. p. 19.9°. E. Scherubel

Preparation of unsaturated higher alcohols by zinc catalyzer. I. Formation of unsaturated higher alcohol from perilla oil. Yuiti Sinozaki and Sizuo Sumi. *J. Agr. Chem. Soc. Japan* **15**, 531–6(1939). —Zn dust was the best catalyzer for the prepn. of unsatd. higher alc. by hydrogenation of oil under high pressure. When perilla oil was heated at 320° under 125 atm. for 2 hrs., the yield was max. A large amt. of linoleyl alc. was obtained from the reaction product. **II. Influence of the addition of lower aliphatic alcohols upon the catalyzer.** *Ibid.* 537–41.—When Me esters of fatty acids or oils were hydrogenated, the formation of unsatd. higher alcs. increased. It may be that the Zn dust was activated by MeOH. When 2 mols. of MeOH and more were added to 1 mol. of soybean oil, the reaction was accelerated. This phenomenon was specific for Zn dust catalyzer; the action of MeOH was the opposite for other catalyzers. While MeOH and EtOH accelerated Zn dust catalyzer, other aliphatic alcs. had the opposite effect. When MeOH was added to Zn dust catalyzer, the yield of unsatd. alc. was 80–90%. Y. Kihara

Sources of oil which have been overlooked previously. E. Wagner. *Seifensieder-Ztg.* **66**, 779–80(1939).—A tabulation of 48 plants growing in Germany, the oil content of their seeds, its properties and uses. A. G.

By-products and residues in producing vegetable oils M. Singer. *Seifensieder-Ztg.* **66**, 720–2, 740–1, 760, 770–1, 800(1939).—Review. A. Guillaudeu

Contact countercurrent bleaching of vegetable oils. John W. Hassler and Ralph A. Hagberg. *Oil and Soap* **16**, 188–91(1939).—After an adsorbent has done its work on an oil it still has reserve power for removing color from unbleached oil; and in order to utilize this reserve adsorptive power the following scheme is employed: (1) The unbleached oil is treated with partially used C and then filtered. (2) The press cake is rejected and the partially bleached oil is treated with fresh C. (3) This is then filtered giving a finished oil and the partially spent carbon. (4) The latter supplies the adsorbent for treating a new batch of unbleached oil. The process can be continued indefinitely. By this countercurrent treatment there is a saving of as much as 40% in the cost of adsorbent and also a gain in the reduced oil retention owing to the use of less adsorbent. Five tables of results are given. E. Scherubel

Cottonseed and the Southern Regional Research Laboratory. D. F. J. Lynch. *Oil and Soap* **16**, 194–7 (1939).—The commodities selected for initial study in the Southern Regional Research Lab. are cotton, peanuts and sweet potatoes, and in addn. to research on cottonseed, studies will be carried out on cotton cellulose, the whole cotton plant, peanut oil and protein, sweet-potato starch and other products and by-products of the assigned commodities. E. Scherubel

Report of the Refining Committee 1938–9. *Oil and Soap* **16**, 197–204(1939). —Results are tabulated for A. O. C. S. Com. coöperative refining tests on 4 samples each of extd. and expeller samples of soybean oil. With 7/8 max. lye (14°Bé.) on extd. oil, 60.5% of the reported results were within 0.5% of the av. and with 2/3 max. lye (14°Bé.) 69.5% were within 0.5% of the av. The Refining Com. recommends, as a result of the work, that the tentative refining methods for expeller and hydraulic soybean oils, as changed and augmented last year and followed in coöperative program for this year, be adopted as official methods of the A. O. C. S. It is further recommended that the tentative methods for extd. oil, as adopted last year be studied further. E. Scherubel

Soybean-oil foots. III. Isolation of flavin. Kozi Okano, Iwao Beppu and Masatosi Ozu. *J. Agr. Chem. Soc. Japan* **15**, 235–7(1939).—The oil foots were extd. with 60% alc. and then pptd. with phosphotungstic acid. Flavin was isolated from the ppt. It was identified by means of the fluorescence spectrum and the absorption spectrum. **IV. Manufacture of lactation-promoting medicine and tests of its effects.** *Ibid.* 238–42.—The oil foots were mixed with 50% alc. at 60–70° and kept for a few hrs. The middle layer consisting of alc. soln. was made alk. by the addn. of $Ca(OH)_2$ to remove resin, coloring matters, etc., and then acidified to remove saponin, etc. The filtrate was neutralized and evapd. to a yellowish brown powder. It contained a large amt. of stachyose and amino acids. It showed lactation-promoting activity for the cow and human subjects. Y Kihara

Saponification value of waxes by use of mixed solvents. Merlin Wand. *Chemist Analyst* **28**, 53–4(1939).—The difficulty in obtaining the sapon. value of a fat such as montan or carnauba is overcome by the addn. of 10 ml. of toluene to dissolve 2 g. of the wax and by heating under reflux condensation with 25 ml. of 0.7 *N* KOH in EtOH. W. T. H.

Formation of wax ester by hydrogenation under high pressure and the solubilities of wax esters in organic solvents. Yuiti Sinozaki and Siniti Asati. *J. Agr. Chem. Soc. Japan* **14**, 1135–43(1938).—The formation of wax esters from various oils was greatly accelerated when Al_2O_3 or ZnO was added to Cu-Cr-O catalyzer for hydrogenation. The wax ester from soybean oil was more easily sol. in EtOH and more difficultly sol. in turpentine oil or benzine than beeswax. The m. p. and viscosity in turpentine soln. were similar to those of beeswax. They can be used as a substitute for beeswax. Y. Kihara

Spontaneous combustion in the oil and soap industries E. J. Better. *Ind. Chemist* **15**, 361–2(1939). E. H.

Soap builders. Joseph M. Vallance. *Soap* **15**, No. 10, 21–4, 109, 111, 113(1939). The use of old and new substances for extending and improving the quality of soaps is described. Among the newer substances are $Na_4P_2O_7$ and $(NaPO_3)_4$ and methylcellulose, cholesterol, lecithin, wool wax and the unsatd. fat acids of linseed oil and lard known commercially as vitamin F. E. Scherubel

Reversed soaps. J. Warwicke. *Soap* **15**, No. 10, 25–6 (1939). When soap ionizes, Na is the cation and stearate the anion or neg. ion, or the anion-active detergent. Sulfated fatty alcs. belong to the anion-active class. Fatty alc. esters and halogen compds. have the property of giving addn. products with tertiary amines to give compds. which are cation-active. Thus cetyl chloride and trimethylamine give cetyl trimethyl NH_4 chloride and pyridine gives cetyl pyridinium chloride. Both of these compds. belong to the cation-active class giving chloride as the anion while the fatty radical makes up the cation. There is a profound difference between these compds. and soap or sulfated fatty alcs. Separately both deterge and wet, but when mixed they neutralize each other, and in equiv. proportions ppt. one another from soln. leaving a foamless liquor. The reversal of the ordinary process of cleansing a fabric is evident when a cationic soap is added in excess to an alk. soln. of an anionic soap contg. dirt in suspension. Neutralization of elec. charges and redeposition of the dirt take place. The obvious conclusion is that cationic soaps should be used for washing in slightly acid media. The cationic soaps do deterge but their range of activity is different from ordinary soaps or sulfated alcs. They are most useful below a pH of 7.0 and they are often slightly acid in reaction and are useful in dentifrices. They may be compounded with citric and tartaric acids and readily emulsify essential and aromatic oils. E. Scherubel

Filtering material for purifying oils (U. S. pat. 2,170,601) 1.

Purifying animal fats. Emil Andersen-Orris. Brit. 506,968, June 7, 1939. "Oleo" is extd. from crude animal fat by heating the fat to 75°, exactly neutralizing the free fatty acid with alkali and removing the sapond. product by spraying with hot brine, whereupon the neutral fat is run into a crystg. tank maintained at 30–50°, whereby steam seps. and is removed through a filter by suction. App. is described.

Removing fat from animal casings. Lucius M. Tolman and Lloyd E. Dimond (to Wilson & Co.). U. S. 2,171,611, Sept. 5. App. is described, and a method of defatting an animal casing which comprises cleaning the casing, hardening it (suitably by drying) and progressively melting fat upon the surface of the hardened casing and progressively removing the melted fat from the hardened casing by a wringing operation. U. S. 2,171,612 relates to the app. for such use. 1

Preserving fish livers. Ferdinand W. Nitardy (to E. R. Squibb & Sons). U. S. 2,171,594, Sept. 5. Fish livers such as those for extraction of their vitaminiferous oils are cooked and mixed with 1–8% of undissolved boric acid or borax.

Toilet soaps. Ervin Pick. Brit. 506,903, June 6, 1939. The soaps are rendered perspiration preventing by adding thereto CrO_3 and $(CH_2)_6N_4$. $(AcO)_3Al$ may also be added.

28—SUGAR, STARCH AND GUMS

J. K. DALE

The sugar industry of Poland. Anon. *Facts About Sugar* **34**, No. 10, 23–4 (1939).—The geographical distribution of sugar factories in Poland is shown on a map, production statistics are given for the yr. 1919 to 1939, and consumption statistics for 1937–38. F. W. Z. 2

Sugar-juice clarification. Edv. W. Welp. *Facts About Sugar* **34**, No. 10, 38 (1939).—The new cane varieties and the higher milling pressures and maceration used at the present time necessitate the use of more efficient clarifying equipment which removes the greatest possible quantity of suspended and colloidal matter. F. W. Z.

Improved [sugar] factory earnings through technical modernization. E. W. Kopke. *Facts About Sugar* **34**, No. 10, 36–7 (1939); cf. Kopke, *C. A.* **33**, 7139[2]. 4
F. W. Zerban

Cottonseed and the Southern Regional Research Laboratory [studies on sweet-potato starch] (Lynch) **27**. Applied microbiol. investigation in cane-sugar manuf. (Adati) **15**. Action of phytohormones on the development of sugar-beet seedling plants (Willam) **11D**. Manuf. of bagasse pulp (Tanaka, Koriyama) **23**. Filtering material for purifying sugar solns. (U. S. pat. 2,170,601) **1**. 5

Active carbonaceous materials for purifying sugar solutions, etc. Pieter Smit (to N. V. Octrooien Maatschappij "Activit"). U. S. 2,171,408, Aug. 29. App. is described, and a process for the manuf. of catalytically active carbonaceous materials having colloidal properties which comprises finely subdividing a solid carbonaceous material yielding C when subjected to dry distn., such as wood, and quickly mixing the finely subdivided product with H_2SO_4 of a concn. of over approx. 60° Bé., so as to avoid formation of lumps and effect an instantaneous reaction throughout the whole mass which is completed to give a final product within a period not exceeding 10 min. and with a substantially instantaneous rise in temp. to 150–250° so that rapid volatilization of secondary condensable products formed in the reaction occurs. 6

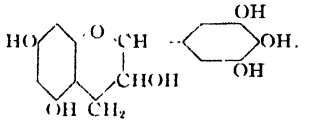
Heat-treatment of massecuite in mixer spouts. Walter E. Smith. U. S. 2,172,040, Sept. 5. App. for improving the operation of centrifugal machines when purging sugar-bearing materials that have been heated above atm. temp. in a tank to increase their fluidity includes a tank adapted to contain said heated sugar-bearing materials, a spout extending a substantial distance from the tank for delivering said material to a centrifugal, said spout having a chamber around it, and means for circulating heated fluid through said chamber at a temp. to keep the material in the spout at substantially the same temp. as the material in the tank. 3

Dialysis membranes for the extraction of sugar from molasses. Sylvania Industrial Corp. Brit. 506,889, June 6, 1939. These consist of H_2O-swelling nonfibrous cellulose, preferably regenerated from viscous or a cellulose ester.

Modified starch. Alfred H. Kelling (to Corn Products Refining Co.). U. S. 2,171,796, Sept. 5. A modified starch suitable *for use in sizing paper* is prepd. by subjecting potato, tapioca or sago starch having a moisture content of 25–55% and admixed with about 1–2% of borax, Na_3PO_4, Na_2CO_3 or NaOH to momentary pressure between rolls heated sufficiently to swell and disrupt the starch cells and give the product a soluble content of 30–65%.

Starch compositions such as those used for treating paper or textile fabrics. James F. Walsh and Willard L. Morgan (to American Maize-Products Co.). U. S. 2,170,271, Aug. 22. Starch is used with a water-sol. acid salt of an amide such as urea hydrochloride or nitrate or acetamide hydrochloride or the like proportioned to have a substantial thinning action on the starch. U. S. 2,170,272, relates to a like treatment of starch with compds. such as glycerol nitrate, aspartic acid sulfate, betaine hydrochloride or various hydrochloric, nitric, sulfuric, phosphoric or oxalic acid salts of glycerols, aspartic acid, glutamic acid, lysine, arginine, tyrosine, phenylalanine or betaine.

Treating potato pulp. Willy Schulze (trading as Stärkefabrik Golssen W. Schulze & Co.). Brit. 507,526, June 16, 1939. The cellulose pulp obtained after the extn. of starch from potatoes is pulverized in a dry state by being subjected to a high-speed centrifugal beating action and the pulverized substance is sifted round the beating zone by a sieve having fine openings that increase in size outwardly. App. is described. 7



29—LEATHER AND GLUE

HENRY R. MERRILL

Characteristics of vegetable and synthetic tanning materials. XV. Determination of the tanning and combining value of vegetable tanning materials. F. Stather and H. Herfeld. *Collegium* **1939**, 453–6; cf. *C. A.* **32**, 6493[7].—A method for detg. total and fixable tannin, based on the filter method and following com. practice in that the tannin soln. is added gradually to the hide powder, is as follows: Wash 5 g. of hide powder in a filter bell with 1 l. H_2O, which should flow through the powder in 3–5 hrs. Drain and adjust the wt. to 130 g., then add 125 cc. of clear, 6%, tannin soln., either adding 25 cc. of tannin soln. at ½-hr. intervals and shaking for 3 hrs. or adding 25-cc. portions at 1-hr. intervals and shaking for 24 hrs. Filter and evap. 20 cc. of filtrate for nontannin. Also evap. 10 cc. of filtered tannin soln. and obtain total tannin by difference. Wash the tanned powder in the filter bell for 12 hrs. with 9 l. H_2O, dry and weigh the residue to det. irreversibly fixed or fixable tannin. During washing, the bell may be set in a beaker supported in a funnel so that the wash water flows through the hide powder, then up through and overflows the beaker.— I. D. Clarke 9

Vegetable tannins in Formosa. III. Yasuyosi Osima and Hirosi Ito. *J. Agr. Chem. Soc. Japan* **15**, 634–5 (1939); cf. *C. A.* **33**, 6640[6].—The tannin contents in the barks of *Pithecolobium dulce* Benth., *Casuarina equisetifolia* L., *Ficus elastica* Roxb., *Bischoffia javanica* Blume, *Elaeocarpus serratus* L., *Liquidambar formosana* Hance, *Elaeocarpus elliptica* Nakai and *Ficus religiosa* L., and in

the wood of *Melaleuca leucadendron* L. were, resp., 26.6, 16.8, 14.3, 4.4, 18.1, 10.9, 13.8, 8.7 and 2.4%. Tannin from *Casuarina equisetifolia* L., *Ficus elastica* Roxb. and *Bischoffia javanica* Blume were easily adsorbed by hide powder. The adsorption was min. at pH 5. **IV. Casuarin, a new catechol from the bark of Casuarina equisetifolia L.** Yasuyosi Osima. *Ibid.* 636-8.—The bark was extd. with hot H_2O. The ppt. was obtained from the ext. by satg. with NaCl. The filtrate was extd. with EtOAc. From the $CHCl_3$-insol. aq. fraction of the ext., fine colorless needles m. 181-3° were isolated. It had $[\alpha]_D^{23.5°} = +19.7°$ in 50% acetone. It was called casuarin. It showed the reactions of gallocatechol. The hexaacetyl deriv. was a colorless prism m. 127 8°. It had $[\alpha]_D^{19°} = +34.3°$ in acetone. The pentamethyl deriv. gave colorless needles m. 156-8°. It had $[\alpha]_D^{19°} = +29.1°$ in acetone. When the Me deriv. was heated with metallic Na, a colorless plate m. 89° was obtained. It was identified as α-(2,4,6-trimethoxyphenyl)-γ-(3,4,5-trimethoxyphenyl)propane. Hence the constitution of casuarin may be a *d*-form of gallocatechol as follows:

In *Bull. Agr. Chem. Soc. Japan* **15**, 108-9(1939)(in English). Y. Kihara

Ellagitannins. L. Reichel and E. Ulsperger. *Naturwissenschaften* **27**, 628(1939).—Ellagi-type tannins have been prepd. from native materials in cryst. form. Dividivi tannin, $C_{42}H_{26}O_{26}$, on hydrolysis produces 1 mol. ellagic acid and 4 mols. gallic acid; hence it is tetragalloylellagic acid. In similar manner myrobalan, algarobilla, valonia, oak gall and Aleppo tannins are built up. In the leaves of *Quercus pendiculata* tetragalloylellagic acid is likewise found in acid form in the presence of catechol and catechol-like tannins. The carboxyl groups of the depside in the tannins are either free or neutralized with salt formation. B. J. C. van der Hoeven

Studies in aldehyde tannage. II. The mechanism of aldehyde tannage. Edwin R. Theis and Wm. Priestly, Jr. *J. Am. Leather Chem. Assoc.* **34**, 566-89(1939); cf. *C. A.* **31**, 2856².—Theories of HCHO-amino acid combination are reviewed. By assuming combination of HCHO with collagen depends on presence of free NH_2 groups, it is deduced that time of soaking or liming hide should affect subsequent HCHO fixation, owing to (1) liberation of NH_3 groups and (2) deamnization. Skin was soaked 1 to 6 days at pH values of 2 to 10, and subsequently tanned 24 hrs. in 1% HCHO soln. at the same pH values. Combined HCHO was estd. by the Highberger-Retzseeh method (*C. A.* **33**, 3199⁵). At all pH values increasing the soaking time from 1 to 2 days resulted in doubling the wt. of HCHO fixed, but further increase in soaking time resulted in progressive decrease in HCHO fixation. The latter effect was most marked in alk. soln. and least marked in neutral soln. It is assumed that liberation of free NH_2 groups predominates in the early stages of soaking, while deaminization predominates in the later stages. Skin was limed 1 to 15 days either in satd. $Ca(OH)_2$ or in satd. $Ca(OH)_2$ + Na_2S. The resulting pelt, after washing, was tanned 24 hrs. at pH = 8 in 1% HCHO. Again the wt. of HCHO fixed was max. for pelt limed 2 days. Fixation by pelt limed with Na_2S was slightly greater than for pelt limed with $Ca(OH)_2$ only. The effect of pH value in tanning was studied, with bated pelt, tanned 24 hrs. at pH values from 1 to 12 in 1% HCHO. The shrinkage temp. and percentage of contraction of the resulting leathers were detd., as well as wt. of HCHO fixed. Results are in harmony with the idea that HCHO tannage is a 3-fold process (1) combination with imino groups of the "short link" in acid soln., and increasing combination with histidine and some lysine NH_2 groups up to pH = 6; (2) increasing combination with remaining lysine residues between pH 6 and 10; (3) progressive combination with arginine residues above pH = 10. Combined HCHO was almost const. from pH = 3 to 7, and thereafter rose rapidly with pH value. Shrinkage temp. increased with pH value, from 44° for pelt tanned at pH = 1 to 77 for pelt tanned at pH = 3, but further increase in pH value caused a very slight increase in shrinkage temp. However, percentage of contraction dropped stepwise with increasing pH of tannage, from about 66% (pH = 3 to 6) to 60% (pH = 7 to 10), to 45% (pH = 10 to 12). Increasing temp. and increasing concn. both caused increased HCHO fixation, and increase in shrinkage temp., especially at pH = 10, where max. fixation from 5% HCHO exceeded theoretical combining capacity for free NH_2 groups of collagen, probably because of fixation of di- or trimethylol compds. The presence of neutral salts greatly increased HCHO fixation in the pH range 4 to 7, probably because the salt weakens the cross linkage between adjacent NH_3^+ and COO^- groups. In the presence of *N* KCl, the wt. of HCHO fixed was doubled in this pH range, but little affected above pH = 8. H. B. Merrill

Two-bath chrome tanning for the manufacture of kid leather. E. Bělavský. *Collegium* **1939**, 444-52; cf. *C. A.* **28**, 3265⁵.—The basicity of the Cr salt on the fibers of full, smooth kid leather is 90-92%. Such a Cr salt is formed by the reaction $4H_2Cr_2O_7 + H_2SO_4 + 6H_2O = Cr_8(OH)_{22}SO_4 + 6O_2$. Reduction of $H_2Cr_2O_7$ with $Na_2S_2O_3$ may follow 3 paths forming the basic Cr salt and either Na_2SO_4, Na_2SO_4 and S, or Na_2SO_4 and $Na_2S_4O_6$. Two-bath tanning is now done in a drum instead of a paddle, and there is much less loss of material in the spent liquors. The American method is to drum the skins for 6 hrs. in each of the following baths: 2.5% $Na_2Cr_2O_7$ and 1.5% H_2SO_4 (95.6%); 18% $Na_2S_2O_3$ and 4% H_2SO_4. The Russian method is to pickle in 0.5% HCl (30%), 10% NaCl, and 50% H_2O for 15 min., then in 0.65% H_2SO_4 and 10% H_2O for 45 min., and tan in 2.5% $Na_2Cr_2O_7$, 4% alum, 50% H_2O for 2-2½ hrs.; 12% $Na_2S_2O_3$, 50% H_2O for 1 hr., then 2.5% H_2SO_4 (95%) in 20% H_2O in 3 portions at hr. intervals. Koehler (*C. A.* **23**, 5608) prepd. one-bath Cr liquors by using Cr alum to supply the acid necessary for reduction of the dichromate with thiosulfate. A two-bath method based on this principle has been worked out for use with a drum. It is shorter than the old method and gives somewhat better leather. I. D. Clarke

Some notes upon the effect of the orthophosphates upon chrome-tanned leather. Robert M. Lollar. *J. Am. Leather Chem. Assoc.* **34**, 556-66(1939).—Ten-g. samples of dried, commercially tanned Cr leathers were continuously extd. (percolation) with 5 l. of H_3PO_4 (0.01 to 1 *M*), or NaH_2PO_4, Na_2HPO_4 or Na_3PO_4 (0.01 to 0.5 *M*). Time of contact was 6 to 7 hrs. at about 25°. The samples were analyzed before and after treatment, and extent of removal of Cr and SO_4 was calcd. In H_3PO_4, Cr removal (about 75%) was independent of concn. In NaH_2PO_4, Cr removal was less than in H_3PO_4, and increased linearly with concn. In Na_2HPO_4 and in Na_3PO_4, removal of Cr increased rapidly with concn., reaching max. values of 32 and 50%, resp., in 0.5 *M* solns. In Na_2HPO_4 and Na_3PO_4, sulfate removal was complete at all concns. In H_3PO_4 and NaH_2PO_4, sulfate removal increased rapidly with concn. but approached 100% rather slowly. Analyses showed that Cr-bound acid was more readily removed than protein-bound acid. Extns. with mixts. of the 4 orthophosphates at pH values from 2 to 12.2 showed that Cr removal was min. at pH = 6.3 for 0.05 *M* solns., and that the min. shifted toward the acid side with increasing concn. Removal of sulfate increased both with concn. and pH value. H. B. Merrill

The stability of leather as indicated by different Procter and Searle values and by pH values. Roy C. Bowker and Everett L. Wallace. *J. Am. Leather Chem. Assoc.* **34**, 551-5(1939).—Com. vegetable-tanned leathers were adjusted during loading to give Procter-Searle values of 0.85-1.36% apparent mineral acid as H_2SO_4. The pH values of aq. exts. of these leathers varied from 2.98 to 3.26. After storage for 2 yrs., none of the leathers showed appreciable loss in strength, confirming previous conclu-

sions that leathers with pH values of 3 or higher do not undergo acid deterioration regardless of abnormally high Procter-Searle values. H. B. Merrill

The tannin-precipitating action of partially degraded glue and gelatin solutions. Géza Tóth. *Collegium* **1939**, 439–43.—Fixation by gelatin of the sol. tannin in leather is not satisfactory because of the high viscosity, low diffusion velocity, and consequent nonpenetration of the gelatin. Boiling a 10% gelatin soln. contg. either 2% of acetic or 4% of formic acid for as much as 12 hrs. did not decrease its tannin-pptg. power but decreased its viscosity to about half its original value. Strong acids decreased the ability of the gelatin to ppt. tannin. I. D. Clarke

Colorimetric detn. of Cr [in leather] (Uebelacher, Droscher) **7**. Condensation products for use in tanning (U. S. pat. 2,171,963) **13**.

Tanning material. Alfred Russell and John W. Copenhaver (to Röhm & Haas Co.). U. S. 2,171,806, Sept. 5. In prepg. a tanning material suitable for making white leather or for use in retanning, at least one aromatic nucleus of 4,4′-dihydroxydiphenylsulfone is sulfonated to form a water-sol. product and this sulfonated product is condensed with an aldehyde such as CH_2O.

Rotary, glass-lined metal drum suitable for use in dyeing or tanning leather, etc. Melville J. Goodwin (to Pfaudler Co.). U. S. 2,170,712, Aug. 22. Various structural details.

White leather. John A. Wilson (to Hall Laboratories, Inc.). U. S. 2,172,233, Sept. 5. For making white leather, a skin such as a calf skin is bleached, treated with an acid CH_2O soln. and then with an alk. CH_2O soln., thereafter treated with an alkali metal metaphosphate soln. of a pH about 2.0–2.4, and subsequently treated with an alum tanning soln.

Edge staining of materials such as leather. Stig E. Rosenberg. U. S. 2,170,218, Aug. 22. Various details of app. and operation.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

New products of the rubber industry. J. W. Raynolds. *J. Chem. Education* **16**, 486–91(1939). E. H.

The Netherlands' rubber industry. H. C. J. H. Gelissen. *Rubber* (Amsterdam) **2**, No. 5, 4–6(1939). N. B.

Viscosity and creaming capacity of latex. J. W. van Dalfsen. *Arch. Rubbercultuur* **23**, 1–28(1939).—The difference between the dry rubber content of cream and that of the original latex is considered to be the creaming capacity. Measurements were made of this capacity in latexes subjected to various preliminary treatments such as prompt and delayed ammonation of original latex, artificial thickening, addn. of soap (or Igepon) and passage through a centrifuge or colloid mill. The av. creaming capacity increased as the observed viscosity diminished, regardless of the pretreatment. Konjaku flour was used as creaming agent. D. E. Cable

Notes on the method of Roberts for the analysis of raw rubber. G. M. Kraay and R. F. A. Altman. *Arch. Rubbercultuur* **22**, 223–30(in English, 231–8)(1938).—"Caoutchol" as isolated by Roberts (cf. *C. A.* **32**, 4821[8]) is believed to be a complex mixt. of oxidation products of rubber hydrocarbon. Users of the method should guard against oxidation during the sepn. steps, using N gas and peroxide-free solvents where required. This modified method may serve as an indicator of oxidation products in rubber. D. E. Cable

The determination of the dry rubber content of cream serum. G. E. van Gils. *Arch. Rubbercultuur* **23**, 29–31 (1939).—A serious error in finding the dry rubber content of latex or cream serum may be caused by copptn. of proteins. Details are given of a procedure to avoid such a fault. The serum is heated with NaOH. Rubber is pptd. after foam formation caused by acidification with formic acid and the presence of decompg. carbonates. D. E. Cable

Tests on crepe soling. IV. Viscosity, plastic yield and tensile product. T. H. Messenger and J. R. Scott. *J. Rubber Research* **8**, 79–86(1939); cf. *C. A.* **31**, 8250[9].—The tendency of soling crepe with a high tensile product to give highly viscous solns. in C_6H_6, already indicated in earlier expts. (cf. *C. A.* **29**, 6466[8]), was confirmed, and the same relationship was found to be true of solns. in acidified C_6H_6 (cf. Vries, *C. A.* **18**, 2441). However, in neither case was the relationship close enough to make it possible to distinguish crepe with unsatisfactory tensile properties by means of a viscosity detn. The advantages claimed for acidified C_6H_6 as a solvent in viscosity detns. are apparently of no aid in distinguishing rubbers of the same type. The rate of plastic yield of gristly crepes is, in an approx. way, inversely proportional to the tensile product. This relationship is closer than that between viscosity and tensile product, so that a plastic yield test is more satisfactory than a viscosity detn. as a criterion of the quality of gristly crepe. Golden crepe is an exception to this rule. Hence, in spite of the operative disadvantages of the plastic yield test, it should be capable of indicating tensile properties and the tendency of soling crepe to "spread" in service. In view of the great changes which soling crepe undergoes at its several transition temps., it is important to know its normal condition in service. Until this is known, tests of crepe for soling are of limited value. Although "plastic yield" is used to denote continuous deformation under a small load, crepe at 70° is neither a plastic material nor a highly viscous fluid. Judged by tensile and viscosity tests, factory crepes are not inferior to estate crepes, but since both detns. involve heating the crepe, the same relationships are not necessarily true in ordinary service. C. C. Davis

Who was Charles Goodyear and how did he come to discover vulcanization? A. van Royen. *Rubber* (Amsterdam) **2**, No. 5, 14–18(1939). N. Bekkedahl

The vulcanization process of rubber: its development and technical significance between 1839 and 1939. A. van Rossem. *Rubber* (Amsterdam) **2**, No. 5, 7–11(1939). N. Bekkedahl

Polarographic method for detg. org. peroxides [in studying primary and by-products of the rubber industry] (Dobrinskaya, Neiman) **7**. Preliminary data on the storage of *Hevea* pollen (Dijkman) **11D**. Expts. on the preservation of ramie lines in sea water by impregnation with latex (Markus, Dallsen) **25**. Resilient articles such as tires (U. S. pat. 2,171,805) **13**. Applying sheet rubber to large rolls (U. S. pat. 2,172,005) **23**.

Latex compositions. Everett V. Anderson (to United States Rubber Products Inc.). U. S. 2,172,463, Sept. 12. See Can. 379,560 (*C. A.* **33**, 3631[8]).

Rubber compositions. Cunard White Star Ltd., Geo. M. Paterson, John Brown & Co. Ltd. and James M. McNeill. Brit. 506,863, June 6, 1939. A ship's hull or analogous structure has its exposed plate edges faired by fillets of rubber latex compounded with a dehydrating binder and a comminuted filling substance. A suitable compn. is rubber latex 3, cementitious binder 6 and granulated cork 2 parts.

Apparatus for triturating rubber and like materials. Manuel Roca and Enrique Guix. U. S. 2,171,949, Sept. 5. Various structural, mech. and operative details.

Rubber powder. Centrale Vereeniging tot beheer van proefstations voor de overjarige cultures in Nederlandsch-Indie (Jan Willem van Dalfsen, inventor). Brit. 506,902, June 6, 1939. This is made from rubber latex to which has been added S or other vulcanizing agent, ZnO or other

activator of the vulcanizing agent, and a stabilizer, e. g., NH_3-caseinate soln., and which is then allowed to stand, with or without acceleration by heat, until the tensile strength of a dried film or the coherence of a coagulum made from a portion of the mixt. has substantially disappeared, the rubber being then sepd., e. g., by spraying, drying as a film, coagulating and filtering or centrifuging. The product is a powder or may be easily disintegrated. It appears to lie between the vulcanized and unvulcanized states as part of the S is combined, and upon further heating, especially if an accelerator is present, it reacquires tensile strength and the other characteristics of vulcanized rubber. Fillers, softeners, antioxidants, etc., may be added to the latex and, where a large amt. of S is used, the product is suitable for the manuf. of an ebonite press powder. The product may be dispersed in H_2O or salt solns. to produce a latex, or swollen in a solvent to give a dispersion that may be ground to give a nonsticky paste of very high rubber content. The powder may be mixed with asphalt *for road purposes*, or used alone or mixed with artificial resins as a molding powder, or used in the manuf. of rubber derivs.

Controlling the temperature of rubber-mill pans, etc. Fernley H. Banbury (to Farrel-Birmingham Co.). U. S. 2,170,396, Aug. 22. Various structural and operative details of app. which may be cooled or heated by circulating water.

Rubber strips from dispersions. Raymond W. Albright (to American Anode Inc.). U. S. 2,170,441, Aug. 22. App. is described, and a method which comprises continuously passing a surface such as a Zn tape through an aq. dispersion of rubber, depositing a continuous coating of water-contg. rubber coagulum on the surface, severing the coating longitudinally into strip form promptly and before substantial drying of the coagulum has occurred, and drying the strips of coagulum.

Sponge rubber. Expanded Rubber Co. Ltd. and Francis De Lautour. Brit. 506,077, May 23, 1939. In the manuf. of gas-expanded rubber, the rubber is partially vulcanized, e. g., to 2–15% of the final cure, gassed at atm. temp. and subsequently heated in a mold to complete the vulcanization and expansion of the gas. The pressure in the gassing chamber at the completion of the gassing operation is preferably released rapidly to cool the contents of the chamber so they may be readily removed; the cooling effect may be prolonged by conducting the cooled gas through a jacket around the gassing chamber.

Porous rubber products. Edward A. Murphy, Geoffrey W. Trobridge and Albert N. Ward (to Dunlop Rubber Co. Ltd.). U. S. 2,169,847, Aug. 15. In producing an article such as a cushion for upholstery, spaced projections of a former are dipped into a mass of foamed latex to form deposits on the side walls of the projections which are joined together in a continuous structure.

Rubber sheets. Wadysaw Kubica. Brit. 506,942, May 19, 1939. Thin sheets are manufd. in a continuous manner by drying a layer of rubber soln. or of an aq. rubber dispersion on a polished unheated drum that rotates with const. speed and is partly immersed in the soln. or dispersion in a container, the sheet being constantly removed by a roller. The sheet formed on the drum may be continuously applied to a fabric led around a roller pressing against the drum. The fabric may be precoated with thin rubber soln.

Rubber sheets. United States Rubber Products, Inc. Brit. 505,959, May 19, 1939. Sheet material, e. g., inner tubes for pneumatic tires, that is resistant to tearing has a no. of sepns., each having contiguous edges defining closed paths, located over the surface of the sheet and extending partly through the thickness of the sheet. The material may be made by applying a perforated sheet of unvulcanized rubber to an unperforated sheet of unvulcanized rubber, dusting at least the perforations with soapstone, mica, etc., and subjecting the sheets to heat and pressure so as to vulcanize them together and to cause the rubber of the unperforated sheet to flow into the perforations of the perforate sheet.

Use of rubber hydrochloride, etc., as a wrapping and packaging material. Thomas A. McCoy. U. S. 2,168,651, Aug. 8. Materials such as fruits, vegetables, bottles, cartons, etc., are sealed at atm. pressure in a loosely fitting wrapper such as one of rubber hydrochloride stabilized against photochem. disintegration as by $(CH_2)_6N_4$ and the entire surface of the wrapper is heated to a temp. (suitably about 95–110°) and for a time (suitably about 5 sec.) sufficient to shrink the wrapper to fit the contents closely without developing even temporary tackiness.

Laminated conveyer belts of fabric and rubber. Reuben E. Winch (to B. F. Goodrich Co.). U. S. 2,168,013, Aug. 1. Various structural and mfg. details of belts suitable for conveying rock, coal or ore.

Golf balls. Dunlop Rubber Co. Ltd. and Douglas F. Twiss. Brit. 506,205, May 24, 1939. Golf balls having a core filled with a substantially nongaseous material surrounded by tensioned rubber winding and a gutta-percha shell are treated by introducing into the core by means of a hypodermic needle a substance that reacts chemically with that in the core. The reaction may be such as to produce a gas or to liquefy a solid core material, e. g., gelatin. Gas-producing reagents may be NH_4Cl and $NaNO_2$, urea and NaBrO, or an acid soln. of urea and $NaNO_2$. Liquefying reagents for gelatin may be NH_4SCN or urea or a soln. of microorganisms. The injected materials may be heated to help the reaction.

Insulation for cables. P. P. Nikotin, P. N. Gorshkov, G. M. Nodel'man and N. A. Chesnokov. Russ. 51,649, Aug. 31, 1937. A compn. of synthetic rubber, fillers and diphenyl phosphate or ditolyl phosphate is specified.

Rubber-like products. Standard Oil Development Co. Brit. 506,427, May 26, 1939. Vulcanized products are prepd. by treating an isobutylene polymer of mol. wt. below 40,000 with 1–100% of its wt. of S_2Cl_2 or SCl_2 at 80–200° for 10 min.–50 hrs. Fillers and reenforcing agents, e. g., C black, PbO, ZnO, and rubber vulcanization accelerators, e. g., $(CH_2)_6N_4$, di- or tri-phenylguanidine, may be mixed with the polymer before treatment, which may be conducted in the presence of a solvent or diluent, e. g., naphtha, CCl_4, CS_2. The product may be pptd. from the solvent by alc. or Me_2CO and purified by soln. in C_6H_6, addn. of diatomaceous earth and filtration through powd. NaOH. The products may be used for the prepn. of rubber goods, e. g., tires, and high-pressure lubricants.

Gutta-percha cement. A. S. Turbin. Russ. 51,659, Aug. 31, 1937. A stable emulsion in gasoline is obtained by emulsifying gutta-percha without mastication in a mixer or a similar app.

Organic compounds containing sulfur and selenium. Deutsche Dunlop Gummi-Compagnie A.-G. Ger. 677,895, July 6, 1939 (Cl. 12*o*. 23.03). Substituted or unsubstituted aryl selenohalides or selenocyanides are treated with org. S compds. of general formula XSC(S)Y in which X denotes H or metal, especially alkali metal and Y denotes O or N. Thus, *o*-nitrophenyl selenobromide is dissolved in alc. and treated with K isopropylxanthate to give *o*-nitrophenyl isopropyloxythioformyl selenosulfide. The prepn. of benzothiazolyl *o*-nitrophenyl selenosulfide and *o*-nitrophenyl diethylaminothioformyl selenosulfide is also described. The products are used as *vulcanization accelerators*.

Vulcanizing microporous rubber soles. A. P. Pisarenko and G. A. Sandler. Russ. 51,614, Aug. 31, 1937. Addn. to Russ. 47,075. Vulcanization is effected in molds or frames provided with perforations or equipped with a penetrable layer of fabric to facilitate the removal of gases during the process.

Impregnating and vulcanizing elastic belts. Joaquín Montane Marti. Brit. 505,229, May 8, 1939. Endless driving-belts consisting of a skein of rubber threads encased in woven tubular fabric are impregnated with rubber latex by immersion in a bath in which they are alternately stretched and slackened, this motion being continued after removal from the bath, and are then subjected, after they have dried, to pressure under tension by being rolled between pressing plates, 1 of which is stationary while the other oscillates, and are finally vulcanized. App. is described.

CHEMICAL ABSTRACTS

Vol. 34 **JANUARY 20, 1940** **No. 2**

APPARATUS, PLANT, EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

The concept of "contact" in commercial devices. Jose Piazza. *Anales asoc. quím. argentina* **27**, 145–9(1939).—It is proposed to define "contact" as the relation of surface with respect to vol. The quant. definition of this value, having the dimension l^{-1}, facilitates the study of heat-conducting app., fractional distn., catalysis, crystn., etc. E. M. Symmes

A device for rapid rinsing of absorption towers used in gas-analysis studies. N. F. Childers, D. C. Kiplinger and H. W. Brody. *Science* **90**, 447–8(1939). E. H.

Steam consumption of distilling columns. Paul Vidal. *Bull. assoc. chim.* **56**, 593–9(1939).—A theoretical treatment of the various factors involved is presented, and the practical application of the resulting formulas is discussed. F. W. Zerban

Micro tearing machine for the photomicrographic and microcinematographic examination of materials. Th. Pöschl. *Arch. Eisenhüttenw.* **13**, 189–92(1939).—A small, but very strongly and ruggedly built machine for tensile tests is described with which in particular phenomena at and beyond the flow limit and the flow of materials itself can be observed in detail. A continuous observation of the changes in the fine structure due to mech. stresses and impacts is also possible. Numerous micrographs are reproduced made with a bending test. M. Hartenheim

A hydrogen sulfide recorder. Wilton E. Stackhouse. *Instruments* **12**, 280–2(1939).—The colored soln. resulting from the passage of the gas sample through a reagent specific for H_2S is passed through the liquid cell of a photoelec. photometer. The net photocell output is recorded by means of a potentiometer recorder. The recorder scale covers the range from 0.0 to 0.5 grains of H_2S per 100 cu. ft. of gas, responds to changes in concn. of 0.005 grains within 20 min., and is accurate to ±1%. E. H. Brown

Thermoelements from noble metals. K. W. Fröhlich. *Österr. Chem.-Ztg.* **42**, 356–7(1939).—The Pt-Fe thermoelement has a greater thermotension at a given temp. than the Pt-Rh element. This means higher sensitiveness in the measurement of temp. By the use of the Pt-Rh element, a cheaper millivoltmeter can be used than with the Pt-Rh element with equal accuracy. The Pt-Rh element is best for temp. above 1200°. Joseph H. Wells

An apparatus for taking an average sample of a variable flow of gas. A. Blackie. *J. Soc. Chem. Ind.* **58**, 293–6(1939).—The condition for proportional sampling is attained by maintaining a pressure difference between the receiving vessel and the source equal to the pressure difference between the source and the throat of the Venturi. Two models are described. E. H. Brown

Simple wet combustion method for the determination of carbon, oxygen equivalence and empirical formula by iodic acid oxidation. Bert E. Christensen and J. Fred Facer. *J. Am. Chem. Soc.* **61**, 3001–5(1939).—A simple *app.* for the detn. of O equivalence and percentage of C by means of HIO_3 oxidation is described. A modification of the Pettenkofer method for the detn. of CO_2, using a volumetric principle, has been devised. Equations have been derived by means of which the empirical formula of an org. compd. can be established readily from the data supplied by the above method. C. J. West

Portable apparatus for exact analysis of mine gases, motor exhaust, etc. A. Schmidt. *Glückauf* **75**, 198–203(1939).—A portable app. employing the manometric method of analysis and giving high accuracy with large measuring range is described. A table for pressure corrections, due to changes in temp. during the analysis is given. L. P. Rockenbach

Preparation of pure gases and pentane for cryostats. N. S. Rudenko. *J. Phys. Chem.* (U. S. S. R.) **12**, 668–76(1938).—The prepn. and purification (by low-temp. distn.) of O_2 from $KMnO_4$, N_2 from NH_4NO_2, CO from CH_2O_2, C_2H_4 from $C_2H_4Br_2$, CH_4 from CH_3COONa, and pentane from aviation benzine (by distn., fractional crystn. and washing with H_2SO_4 and NaOH) are described. F. H. Rathmann

Some applications of the Raleigh interferometer. E. C. Craven. *Ind. Chemist* **15**, 354–7(1939).—The compn. of some binary mixts. can be detd. by the direct comparison of interference bands. Analyses of CO_2 in air, AcH in air, higher alcs. in EtOH, explosive petroleum-air mixts. and hydrocarbons in crude H were investigated. CO_2 in air was measured to 0.01%. Two complete O_2 and aldehyde detns. per min. were found possible with the exit air from an AcOH plant. E. H. Brown

Froth flotation economically recovers valuable material from talc waste. W. E. Trauffer. *Pit and Quarry* **32**, No. 4, 28–30(1939).—Economical recovery of 95% pure talc from dry-plant waste (talc 55, magnesite 35 and other impurities 10%) by froth flotation is now possible. Plant equipment and flow-sheet are described. A. G. S.

Measuring flotation reagents. J. C. Williams. *Eng. Mining J.* **140**, 55(Nov., 1939).—Hypodermic syringes furnish uniform drops accurately calibrated. Luer Tuberculine syringes are available in sizes ranging from 0.25 cc. to 50 cc. By the use of interchangeable needles the size of the drop can be varied to suit the reagent used and the requirements of the operator. W. H. Boynton

An automatic carbon dioxide compensator for cupola control. F. K. Vial. *Instruments* **12**, 275–6, 279(1939).—CO_2 is regulated by the operation of an air-supply blower activated by a recording and controlling Orsat type gas analyzer. E. H. Brown

Recirculating air heating for industrial furnaces. Edward Stephenson, Jr. *Metal Progress* **36**, 637–41(1939).—Attention is called to large furnaces operating at temps. up to 1250°F. for process and stress-relieving annealing, and for heat-treatments of steels. Details of burner construction and fan equipment are given. W. A. Mudge

A recirculating radiated waste-heat drier operated under controlled humidity and temperature. H. R. Straight. *Bull. Am. Ceram. Soc.* **18**, 427–9(1939). C. H. Kerr

Direct deduction of average temperature in heat-interchange apparatus. Jose Piazza. *Anales asoc. quím. argentina* **27**, 147–8(1939); cf. *C. A.* **33**, 1995⁹. E. M. Symmes

Graphical determination of heat transmission across a wall. Jean Szczeniowski. *Chaleur et ind.* **20**, 491–4(1939).—Math. H. A. Beatty

Flow and heat-transfer problems in chemical technique and research. Gerhard Damköhler. *Chem. Fabrik* **1939**, 469–77.—A math. discussion of these problems from the phys. chemistry standpoint under the general headings, "Pure flow and heat-transfer problems without direct connection with the chem. process," and "Problems in which the phys. influences of the flow, of diffusion and of heat transfer are directly connected with chem. processes." Examples and data are given, with 11 references. J. H. Moore

App. for agitating, aerating, mixing and purifying liquids or gases (U. S. pat. 2,174,147) 14.

Apparatus for producing substantially saturated solutions, such as those of sodium chloride in water. Kenneth E. Stuart (to Hooker Electrochemical Co.). U. S. 2,173,986, Sept. 26. Various structural and operative details of an app. having a plurality of tanks and float valves for liquid control.

Apparatus (with coacting rotating disks) for intimate mixing of various coarsely premixed pulverulent materials. Paolo Gentilli. U. S. 2,172,704, Sept. 12. Various structural, mech. and operative details.

Apparatus for supplying powdered and other material to a mixing vessel. Wm. G. Simon and Frederick R. Simon. Brit. 507,607, June 19, 1939. In the app., an automatic weighing machine intermittently discharges the weighed quantities into a hopper and the outlet from the hopper is controlled to effect a continuous delivery of the material.

Measuring apparatus for the comparative determination of the dielectric constants of powders, grains, cuttings, etc. Haardt & Co. A.-G. Brit. 506,921, June 6, 1939.

Apparatus for taking samples of milk, water, beer or other liquid and means for transporting the apparatus in a sterile condition. Henry M. Gould. Brit. 508,585, July 4, 1939.

Distillation and rectification process and apparatus. Juan Loumiet et Lavigne. Brit. 507,435, June 14, 1939. Liquids are distd. and rectified by causing their vapors to flow through helical coils with a velocity sufficient to develop a component of centrifugal force several times as great as gravity, injecting rectifying liquid into the vapors and causing it to be atomized, and extg. the rectified liquid. The coils may have straight portions. A double-effect app. for the rectification of alc., etc., is described.

Photoelectric colorimeters. I. G. Farbenindustrie A.-G. Brit. 508,802, July 5, 1939.

Manhole doors of the internal type for pressure vessels. Charles McNeil Ltd. and John McNeil. Brit. 507,563, June 9, 1939.

Boiling pans. Harry Pauling. Brit. 508,993, July 10, 1939. A boiler for concg. H_2SO_4, etc., is fitted with 1 or more cone-shaped inserts, not more than half the depth of the boiler, with their surfaces at an angle of about 45° with the horizontal. The inserts are open at the top and bottom and provided with perforations.

Filters. Johannes Wiebe. Ger. 676,189, May 27, 1939 (Cl. 12*d*. 15.02). Addn. to 671,703 (*C. A.* **33**, 6094[9]). A device for removing filter cakes from rotary cell filters is described.

Oil filter suitable for use with various apparatus. Robert H. Pennebaker. U. S. 2,173,978, Sept. 26. A filter unit for oil comprises a spool-like frame having a pair of end flanges interconnected by a central tubular member perforated for the passage of oil therethrough, a filter screen mounted concentrically about the perforated central tubular member, a screen-like supporting strip having a paste-like filtering medium spread thereon and consisting of a mixt. of fibrous material and finely divided clay wetted by a light-bodied oil, the screen-like strip with the paste-like filtering medium thereon being spirally wrapped about the filter screen for providing a plurality of superimposed layers of filtering medium on the filter unit, the paste-like medium penetrating the meshes of the screen-like strip and uniting adjacent layers of the medium to provide a substantially homogeneous filtering mass over the filter screen.

Filtering apparatus constructed to facilitate backwashing to remove collected residue. Charles W. Andrews (to H. A. Brassert & Co.). U. S. 2,173,060, Sept. 12. Various structural and operative details.

Filtration and clarification of liquids. Hubert F. Jordan (to United States Rubber Co.). U. S. 2,173,256, Sept. 19. Various structural and operative details of an app. in which an endless belt of perforated vulcanized rubber or the like is used as a filtering medium.

Funnel with a splash-preventing flange. Ross L. Perkins. U. S. 2,174,228, Sept. 26. Various details of a funnel with a flange and baffles.

Wet separating. Andrew Pearson. Brit. 507,661, June 15, 1939. In the "sink and float" process for concg. minerals by the use of a substantially stable heavy suspension, the tendency of the viscosity of the suspension to increase during the process is controlled by adjusting the relative proportions of the fine and coarse particles in the dispersed phase while the sp. gr. of the suspension is kept substantially const., the adjustment being effected by removing part of that portion of the dispersed phase the particle size of which is intermediate that approaching Brownian size and that which settles rapidly, and replacing it by a suitable amt. of the dispersed phase of larger particle size. The initial suspension may be prepd. by adding to a stable suspension in a liquid of finely levigated galena or other heavy substance that contains a relatively large approaching Brownian size the same substance of coarser grain size until the desired sp. gr. is attained.

Centrifugal separators. I. G. Farbenindustrie A.-G. Brit. 506,488, May 30, 1939. Pulverulent materials are sorted centrifugally in an eddy formed by a carrier fluid that travels in a chamber from periphery to center; the coarse material leaves at the boundary of the chamber and the fine material is withdrawn axially with the carrier fluid.

Centrifugal separators. Aktiebolaget Separator. Brit. 508,182, June 27, 1939. A separator with 1 or more supply and discharge pipes communicating with the bowl by means of a tightening device has 1 element of the tightening device supported in relation to the other by a bearing.

Centrifugal gas separators. Santo Ghielmi. Brit. 508,161, June 27, 1939. Gaseous mixts., e. g., air, are divided into their constituents by the combined effect of centrifugal force and suction produced by app. having a no. of rotary impellers that increase in diam. from the inlet.

Centrifugal dust separators. Archibald F. Lamb. Brit. 506,778, June 5, 1939.

Apparatus for separating sand, etc., from slimes and slurries. Ralph J. Hall. U. S. 2,172,792, Sept. 12. Various structural and operative details.

Gas purifier. Hans Bischoff and Josef Lerch. Ger. 678,114, July 8, 1939 (Cl. 26*d*. 5). Addn. to 676,803 (*C. A.* **33**, 7157[1]). Details of app. contg. a purifying and filtering element are described.

Apparatus for atomizing various liquids. Albert J. Loepsinger (to American Moistening Co.). U. S. 2,173,072, Sept. 12. Various structural details.

Apparatus for measuring the electric conductivity of liquids. Fritz Lieneweg and Wilhelm Geyger (to Siemens & Halske A.-G.). U. S. 2,173,233, Sept. 19. Various structural, elec. and operative details

Apparatus for mixing liquids in flow proportionately. Bedrich Kresl Brit. 506,576, May 31, 1939. In app. wherein a turbine, etc., driven by 1 liquid drives a pump supplying the other, the pump is mounted on the casing of the turbine and is driven by a crank or eccentric.

Apparatus for producing a pulsating circulation of liquids containing gas-evolving products, as in fermenting grape must. Gilbert L. R. Ducellier and Marcel A. Isman. U. S. 2,174,203, Sept. 26. Various structural and operative details

Photoelectric apparatus for testing liquids. Victor H. Gilbert and Radiovisor Parent Ltd. Brit. 509,061, July 11, 1939. Liquids to be tested are subjected to temp. conditions in a chamber in communication with an observation chamber in which the liquid passes between a source of light and a light-sensitive element. App. is described intended to detect the leakage of NH_3 in a cooler unit comprising a tank, a pump and a sprayer.

Apparatus for adding a liquid in proportionate quantities to a stream of a second liquid. The Permutit Co. Ltd., John G. Milton and Robert Clark. Brit. 507,090, June 9, 1939. The app. comprises electrically operated means, actuated by a meter in the 2nd stream, for moving a shoot that in 1 position supplies the 1st liquid to the stream and

in the other position returns the 1st liquid to storage, the return being effected after a predetd. amt. of the 1st liquid has been added.

Apparatus for purifying liquids. John K. Russell, Wm. B. Collins and Walter W. Boggs. Brit. 507,064, June 6, 1939. Addn. to 476,422 (*C. A.* **32**, 3673[2]). The refining element of the app. comprises a finely divided adsorbent material and a large no. of lumps or wads of a fibrous filtering material which supports the adsorbent material, the said materials being arranged in sep. layers and so that flow-impeding packing or settling of the adsorbent material is substantially prevented. The adsorbent material may be activated, e. g., as described in Brit. 476,421 (*C. A.* **32**, 3673[3]) and 476,422, and may consist of chemically or otherwise activated clay of 1 or more degrees of fineness; fuller's earth, synthetic clay, pumice, infusorial earth, diatomaceous earth, kieselguhr and bentonite are specified. The fibrous material may be mineral, rock or steel wool, asbestos, cotton waste, curled hair or paper. The app. may be fitted in the oil circuit of an internal-combustion engine. 2

Air-conditioning apparatus (utilizing calcium chloride for drying). Charles R. Downs and Joseph W. Spiselman (to Calorider Corp.). U. S. 2,174,186, Sept. 26. Various details of an app. for cooling and drying the air.

Apparatus for drying, moistening or other treatment of webs in chambers. Proctor & Schwartz, Inc. Brit. 507,810, June 21, 1939. 4

Drying. Johannes Barthel and Heinrich Huebner Ger. 676,481, June 5, 1939 (Cl. 82*a*. 1.01). Addn. to 644,635 (*C. A.* **31**, 6064[1]). A method of drying materials by a gas, such as air, carrying a unipolar charge of at least 500 v. is described.

Rotating furnace. Stewarts and Lloyds, Ltd. Ger. 679,819, Aug. 16, 1939 (Cl. 18*c*. 9.03). 5

Heat-exchange apparatus suitable for use with liquids and air. Carl E. Meyerhoefer (to E. A. Laboratories, Inc.). U. S. 2,174,038, Sept. 26. Various structural details

Heat-transfer apparatus suitable for heating oils. James M. Jenkins (to Andale Co.). U. S. 2,173,169, Sept. 19. Various structural and operative details of an app. including a heated tube contg. baffles and through which material to be heated is passed. 6

Plate heat-exchangers. The Aluminium Plant & Vessel Co. Ltd. Brit. 508,261, June 28, 1939.

Apparatus for washing ores, etc Fried Krupp Grusonwerk A.-G. (Paul Bodenstein, inventor). Ger. 676,184, May 27, 1939 (Cl. 1*a*. 12.10). Addn. to 674,863 (*C. A.* **33**, 6665[5]).

Apparatus for testing the hardness of materials. Heinrich Hanemann (to (Firm of) Carl Zeiss). Brit. 507,737, June 20, 1939. The app. comprises a penetrator and a microscope for measuring the impressions.

Grinding apparatus. Arno Andreas. Ger. 676,235, June 12, 1939 (Cl. 50*c*. 17.20).

Ball mills for grinding or blending materials. Wm. H. P. Boll. Brit. 508,123, June 27, 1939. The mills comprise a chamber of cube shape mounted for rotation by diagonally opposite corners in such manner that during rotation individual corners assume in succession the instantaneously lowest position and that the balls roll in a series of straight lines at angles to one another in moving to the lowest corner, and 1 of the mounted corners of the chamber includes an expansion bearing. 3

Roller mills. Arnold Locher. Brit. 507,971, June 23, 1939. In a grinding-roller, the roller body consists of a steel tube of which the outer surface is improved by carbonizing or nitriding to the desired depth and up to about 1000 Brinnel, the axle ends being welded into the ends of the drum.

Porous silicate decolorizing agents, etc. Arthur B. Cummins (to Johns-Manville Corp.). U. S. 2,173,085, Sept. 19. A porous product suitable for decolorizing materials such as oils is prepd. by forming a slurry of an alk. earth carbonate such as $MgCO_3$, a finely divided siliceous material such as diatomaceous earth, and water, heating the slurry for a prolonged period to effect reaction, and sepg. the silicate product from the aq. medium.

Apparatus for measuring the moisture content of material, e. g., sand, by mixing a sample with a definite volume of a testing liquid that is miscible with the water. Geoffrey H. Cheesman, Frederick J. Burren and Richard J. Pike. Brit. 506,996, June 2, 1939. The app. comprises a mixing device in which a measure of defined vol. for the material can be inserted and retained adjacent the mouth, removable closure means for the device, and a hydrometer for ascertaining the change of d. of the testing liquid resulting from the admixt. with H_2O.

Inflammable-gas detectors, of the type wherein a differential gas thermometer having one bulb surrounded by a catalyst is provided with electric contacts operating a signaling circuit. Giuseppe Menozzi. Brit. 507,219, June 12, 1939. Addn. to 480,335 (*C. A.* **32**, 5667[6]).

Relation of vertical stability to salinity and oxygen extremes in the Atlantic. R. B. Montgomery. *Gerlands Beitr. Geophys.* **54**, 194–202(1939).—Converging surface water sinks along surfaces of const. potential d., so that potential d. layers reaching the sea surface in regions of strong convergence may be expected to be thicker (less stable) than those reaching the surface in regions of weak or neg. convergence. This effect was investigated with the aid of von Schubert's stability values for the stations of the "Meteor" Atlantic Expedition. In certain cases the layers of relatively low stability can be attributed to strong convergence at their intersection with the surface. The same layers have high O content, which substantiates the supposition that they are strongly supplied with water from the surface. J. F. Schairer

Oxidation, reduction, electroöxidation and electroreduction. H. G. Bös. *Chem. Weekblad* **36**, 671–5 (1939).—New definitions are proposed for the above-mentioned expressions. H. S. v. Klooster

A new edition of the periodic system. H. G. S. Snijder. *Chem. Weekblad* **36**, 676–7(1939).—A modification of Antropoff's arrangement (cf. *C. A.* **32**, 6115[4]) is suggested. H. S. v. Klooster

A method of obtaining the expanded secular equation for the vibration frequencies of a molecule. E. Bright Wilson, Jr. *J. Chem. Phys.* **7**, 1047–52(1939).—Math. G. M. Petty

Internal rotation of 1,1,2-trichloroethane. Anthony Turkevich and J. Y. Beach. *J. Am. Chem. Soc.* **61**, 3127–30(1939).—Electron-diffraction data indicate that 1,1,2-trichloroethane is not a rigid mol. in the cis or trans configuration, nor does it have a sinusoidal potential barrier to internal rotation with the trans configuration the most stable. The most stable configuration is rotated about 50° from the trans position. A potential barrier calcd. from electrostatic and exchange interactions is in agreement with the expts. The C-Cl distance is 1.75 ± 0.03 A. and the C-C and C-H distances are assumed to be 1.54 and 1.09 A., resp. The Cl-C-Cl angle is 111°30 ± 2°. A. B. Garrett

The electron-diffraction investigation of the molecular structures of the meso and racemic 2,3-dibromobutanes. D. P. Stevenson and Verner Schomaker. *J. Am. Chem. Soc.* **61**, 3173–6(1939).—These data indicate that both racemic and meso 2,3-dibromobutane have "trans" configurations, with respect to the Br atoms, the bromine-bromine distance being 4.60 ± 0.03 A. A model of the structure of this pair of compds., based on the known structure of isopropyl bromide, gives a theoretical scattering curve which is compatible with the photographs. There is evidence of considerable torsional oscillation about the equil. "trans" configuration. A. B. Garrett

Structural analysis and chemical bonds. V. Caglioti and G. Giacomello. *Atti X° congr. intern. chim.* **2**, 176–94 (1938).—In mol. structures the temp. coeff. of intramol. forces is small, whereas that of intermol. forces is appreciable. Hence a study of the temp. coeff. may yield information on the type of bond between 2 mols. The type of structure, whether plane, spherical, or chain-like, but when there is no polymerization, depends on the shape and size of the mols. In polymerization, the structural type varies with the direction of polymerization; e. g., chain mols. may give rise to chain structures, layer structures, or structures of the diamond type, if polymerization takes place in 1, 2 or 3 directions, resp. These concepts are applicable to ionic structures. Thus the purely ionic or triequiv. structure (bonds ionic in all 3 directions) corresponds to the diamond-type mol. structure; ionic layer structures (diequiv.) are known too (CdI_2). It is shown that ionic chain structures also exist; the *structure of cryolite*, $6NaAlF_4.4NaF$, is given as an example. The fundamental structure is built up of chains of $NaAlF_4$ groups, parallel to the *c* axis, forming channels in which the NaF groups are located. The direction of the ionic bond is that of the *c* axis. Finally, the existence of *mixed structures* is demonstrated: in a fundamental structure belonging to one of the simple types, groups of another type may occur, which are bonded to the fundamental groups by van der Waals, Keesom and London forces. E. g., in the *structure of* KHF_2, the F-F distance is the sum of the at. and ionic radii of F. The anisotropic properties of solid substances (optic, elec., magnetic, etc.) are referred to the anisotropy in the bonds, viz., their nonequivalence in all 3 directions. J. D. H. Donnay

Structural analysis and chemical bonds. V. The structure of molecular lattices determined by the Fourier method of analysis. V. Caglioti and G. Giacomello. *Gazz. chim. ital.* **69**, 245–54(1939); cf. preceding abstr.—The present work is concerned with the mol. lattice of the cholein complex (I) formed from desoxycholic acid (II) and palmitic acid (III) and with related inorg. complexes. The III mol. lies parallel to the *c* axis, and the plane contg. the C atoms is parallel to the *ac* plane. It constitutes, therefore, an internal axis around which are II mols., each of which lies around the central axis and forms with the other almost a cylinder which envelopes the III mol. This is possible because of the peculiar structure of II as indicated by the Fourier analysis. The I mol. contains 3 hexatomic rings and 1 pentatomic ring, to which the lateral chain is attached. The 1st 2 hexatomic rings are not in the same plane; this accounts for the arched form of the II mol. The combination of the 1st rings has the type of configuration of *cis*-decalin. The 2nd 2 hexatomic rings and the pentatomic ring form a plane in which the 2nd 2 hexatomic rings have the configuration of *trans*-decalin. The positions of the OH and Me groups are explained in detail with the aid of diagrams. The fundamental property of I is the capacity of the III component to arrange around its mol. a lattice of mol. character, whereby the properties of II are changed. Thus the cryst. form, soly. in hot EtOH, soly. in cold EtOH, soly. in cold AcOH and $[\alpha]_D$ value of I and II, resp., are: rhombic, tetragonal; 1:5, 1:2; 1:18, 1:4; great, slight; 48.28°, 57.02°. The fatty acid in cholein complexes can be removed by extn. with xylene; in such a case a new complex is formed with the xylene. In general, then, a cholein complex is composed of a lattice with mol. bonds, in which the cryst. skeleton is composed essentially of II mols. The fatty acid, however, governs the arrangement of the lattice. When once formed, the III lattice can be readily replaced by a compd. of similar constitution or of differing chem. constitution but with filiform mols. Structures of this character, in which a particular compd. acts as an enveloping shell, are known in inorg. chemistry, in which case the elementary cells have vacant positions occupied by various atoms. Various examples of such inorg. coördination are cited, with particular attention to complexes of NH_4Cl and $CoCl_2$. NH_4Cl-$CoCl_2$ complexes and cholein complexes are analogous in that in each case the intermol. forces differ from the intramol. forces, and in each case the 2 components in the complex are related crystallochemically. In anomalous mixed crystals, NH_4Cl is bound to the other salt by forces different from those which characterize the 2 lattices; on the contrary, in I the 2 chem. types are bound by forces other than intramol. ones, and the crystallochem. relations control the formation of definite compds., which depend on the length, form and position of the functional groups in the coördinated

mol. Complexes of the I type differ essentially from absorption complexes of the anomalous mixed-crystal type by the different dimensions and forms of their mols. The former have a relatively simple, cylindrical coördination; the latter have a relatively complex tridimensional coördination. C. C. Davis

Structure of insulin. Maurice L. Huggins. *J. Am. Chem. Soc.* **61**, 2982–3(1939).—An electron d. projection of the insulin structure is given, by using Crowfoot's *hk.O* x-ray data and assuming (incorrectly) that the true projection has a center of symmetry and that the structure proposed by Wrinch and Langmuir (*C. A.* **32**, 7318[8], 8873[4]) is a sufficiently close approximation for the detn. of the symmetry of the structure factors. C. J. West

The ellipsoids of polarization of bonds and octets. Sheng-Nien Wang. *J. Chem. Phys.* **7**, 1015–15(1939).—Math. By use of the method of Sachsse (*C. A.* **29**, 4984[6]) transverse and longitudinal polarizabilities of bonds and octets occurring in simple org. mols. are calcd. The results are more reliable and more regular than the calcns. of Sachsse. G. M. Petty

The stability of the valency angles of the carbon tetrahedron. Dipole moments of stereoisomeric 2,3-dichloro-2-butenes. G. P. Mikhailov and D. V. Tishchenko. *J. Gen. Chem.* (U. S. S. R.) **9**, 782–7(1939).—The dipole moments of stereoisomeric 2,3-dichloro-2-butenes were detd., whereby it was established that in the aromatic and ethylene series isomers with higher b. ps. show higher dipole moments. From the dipole moment obtained for *cis*-2,3-dichloro-2-butene it is evident that there is no deformation of the C tetrahedron in ethylene compds. Gertrude Berend

The dipole moments and structures of ozone, silicobromoform and dichlorogermane. Geo. L. Lewis and Charles P. Smyth. *J. Am. Chem. Soc.* **61**, 3063–6(1939).—The dipole moment of ozone indicates that the mol. is a bent structure with a very obtuse angle between the bonds of 2 oxygens attached to a central atom. These 2 identical bonds have some polar character as a result of resonance among forms contg. semipolar bonds. The moments of silicobromoform and dichlorogermane indicate that Si compds. tend to have min. moments in the group carbon, Si, germanium and tin compds., which, otherwise, increase in the order named. A. P. Garrett

Dipole variation of ether. Norman C. C. Li. *J. Chem. Phys.* **7**, 1068(1939).—Dipole moments ($\times 10^{18}$) are tabulated for EtOH, 1.70; Et_2O, 1.14; EtOBu, 1.2; *iso*-AmOEt, 1.2; Et phenol ether, 1.0; PhOH, 1.70; PhOMe, 1.20; PhOEt, 1.0; Ph_2O, 1.05. Byers' prediction of these values (*C. A.* **33**, 3222[3]) is accurate. G. M. Petty

The dipole moments and structures of certain nitro compounds and amines. Geo. L. Lewis and Charles P. Smyth. *J. Am. Chem. Soc.* **61**, 3067–70(1939).—Tetranitromethane has a large at. polarization but zero dipole moment, which means that it is not trinitromethyl nitrite as sometimes suggested. The moment of nitroform is consistent with its tetrahedral structure. The moment of cyclohexylamine is of the same size as those of the primary alkyl amines. The moment of morpholine shows that it exists primarily in the *Z*- or chair-forms of the mols. A. B. Garrett

The contact potential of an iodine film on tungsten. M. J. Copley and R. W. Spence. *J. Am. Chem. Soc.* **61**, 3027–30(1939).—The contact p. d. at room temp. between a clean W surface and an I-coated W surface is −0.91 v. This value suggests that the adsorbed I atoms on the surface are highly polarized. The dipole moment of these adsorbed atoms is estd. as 1.0 Debye unit. A. B. Garrett

Determination of the dielectric constants of liquids at radio frequencies. III. Methyl alcohol, water, and alcohol-water mixtures. Theoretical. R. M. Davies and T. Tyssul Jones. *Phil. Mag.* **28**, 289–306(1939); cf. *C. A.* **30**, 2062[8].—The detection of resonance with conducting liquids and the correction for lead inductance are considered. **IV. Methyl alcohol, water, and alcohol-water mixtures. Experimental.** T. Tyssul Jones and

1 R. M. Davies. *Ibid.* 307–27.—Dielec.-const. values (ϵ) were obtained with chlorobenzene as a standard for pure MeOH, pure H_2O and for 6 different mixts. The value of ϵ for MeOH is 33.57 at 20°, with a 5° temp. coeff. of −0.193; for H_2O, $\epsilon_{20} = 80.31$, with a temp. coeff. of −0.363. With mixts. in the concn. range 20–80% alc. $\epsilon_{20} = 81.16 - 0.4656\ p$, where p is the concn. Outside these concn. limits ϵ is not a linear function of p. The 2 agreement of these values with those of other workers is discussed. E. J. Rosenbaum

Magnetic susceptibilities of metallic oxides, with special reference to those of chromium and manganese. S. S. Bhatnagar, A. Cameron, E. H. Harbard, P. L. Kapur, A. King and Bram Prakash. *J. Chem. Soc.* **1939**, 1433–41.—Magnetic data previously reported by various obsers vers for metallic oxides are frequently contradictory and very difficult to interpret theoretically. These earlier 3 results are discussed critically. Then the results of an intensive study of the magnetic properties of the oxides of Cr and Mn over a wide range of temps. by the modified Guoy magnetic balance method, made simultaneously at Lahore and at London, are presented. The simple Curie law, $\mu_B = 2.839\sqrt{\chi_m T}$, neglects interaction between mols., and values of magnetic moment calcd. by this equation are shown to have no theoretical interpretation. 4 However, values of magnetic moment calcd. by the Weiss modification of the Curie law, $\mu_B = 2.839\sqrt{\chi_m(T-\theta)}$, are consistent for specimens prepd. by different methods, and have real theoretical significance. The results are applied to the interpretation of the various formulas suggested for the oxides of Cr and Mn. A magnetic study of the decompn. of CrO_3 shows that there is little change in magnetic susceptibility with variation in compn. in nonstoichiometric oxides, but the nonstoichiometric Cr_6O_9 5 is ferromagnetic. The slight differences in susceptibility found for Cr_2O_3 prepd. by different methods are ascribed to the presence of traces of chemisorbed gaseous elements. The susceptibility of Cr_2O_3 at 32° is $25.6 \pm 0.2 \times 10^{-6}$. W. W. Stifler

Magnetic measurements of hexaphenyldigermane. P. W. Selwood. *J. Am. Chem. Soc.* **61**, 3168–9(1939).—These measurements set upper limits of dissocn. at 1% 6 in the solid and 20% in a nearly satd. benzene soln. at 25°. It is considered improbable that any dissocn. takes place under these conditions. A. B. Garrett

Elementary range of ferromagnetism. R. Haul and Th. Schoon. *Z. Elektrochem.* **45**, 663–71(1939).—γ-Fe_2O_3 was prepd. by oxidation of Fe pentacarbonyl. The magnitude of the primary crystals decreases with decreasing reaction temp. until finally prepns. are obtained amorphous to x-ray. When crystal identification by means of x-ray is no longer possible, electron rays are used. The magnetic susceptibility is measured by the cylinder method with different field strengths. Up to a range of lattice magnitudes of about 30 to 40 A., there is a slight increase in susceptibility, which then rises about 10% to the amt. characteristic of ferromagnetic substances. This experimentally detd. value marks the lowest elementary particle at which spontaneous magnet- 8 ization occurs. H. Stoertz

Partition functions, degree of dissociation and degree of ionization of gases. Karl H. Riewe. *Z. physik. Chem.* **A184**, 393–8(1939).—Theoretical. Formulas for the partition function of partially dissocd. and ionized gases are presented as well as those for calcg. the degree of dissocn. and of ionization. Victor R. Deitz

Thermodynamic functions for a Fermi-Dirac gas. Edmund C. Stoner. *Phil. Mag.* **28**, 257–86(1939).— 9 After an introduction on thermodynamic functions and their relation to statistical formulas, expressions are given for the energy, heat content, Helmholtz and Gibbs free energies and entropy of a gas obeying the Fermi-Dirac statistics. These expressions are obtained in terms of integrals which have previously been evaluated (*C. A.* **32**, 3689[3]). Numerical values are tabulated with characteristic temp. as a parameter. E. J. R.

The statistical mechanics of condensing systems. VI.

The treatment of a system of constant energy. S. F. Streeter and Joseph E. Mayer. *J. Chem. Phys.* **7**, 1025–38(1939); cf. *C. A.* **33**, 1581[6].—Math. Equations for the thermodynamic functions of an imperfect gas are calcd. up to and including the pressure of condensation for a one-component system consisting of chemically satd. mols. G. M. Petty

Density and vapor pressure at low temperatures. II. Nitrobenzene. V. G. Gurevich and K. K. Sigalovskaya. *J. Gen. Chem.* (U. S. S. R.) **9**, 1326–8(1939); cf. *C. A.* **31**, 8283[7].—As the temp. rises from 15 to 53° the vapor pressure of $PhNO_2$ increases from 0.039 to 1.29 mm. of Hg and the d. changes from 0.27 to 7.8 mg. per l. J. L.

Vapor-liquid equilibrium. IV. Carbon tetrachloride-cyclobenzene mixtures. Geo. Scatchard, S. E. Wood and J. M. Mochel. *J. Am. Chem. Soc.* **61**, 3206–10 (1939); cf. *C. A.* **33**, 1562[7].—The vapor-liquid equil. pressure and compns. of CCl_4/C_6H_{12} mixts. were measured at 40 and 70° over the whole compn. range, and at 30, 50 and 60° for approx. equimol. mixts. The ds. were detd. at 25°. Equations are derived for the thermodynamic functions, including the entropy and energy of mixing at const. total vol. The dependence upon compn. agrees with the predictions of the simple theory. The unexplained entropy increase on mixing is only 1/13 as large as for C_6H_6/C_6H_{12} mixts. A. B. Garrett

Pressure of the saturated vapor of two volatile liquids mixed in arbitrary proportions. N. D. Litvinov. *J. Phys. Chem.* (U. S. S. R.) **13**, 119–23(1939).—Using the exptl. data of Zawidzki (*Z. physik. Chem.* **35**, 129 (1900)), L. shows that the consts. of the integrated Duhem-Margules equation can be more simply obtained than as suggested by Margules and Zawidzki. The agreement between the calcd. and the found vapor pressures of arbitrary mixts. of the systems C_6H_6–$C_2H_4Cl_2$, CH_3COO-C_2H_5–CCl_4, CS_2–$CH_2(OCH_3)_2$, CS_2–CH_3COCH_3 and CH-Cl_3–CH_3COCH_3 is very good. F. H. Rathmann

Turbulent liquid motion outside a circular boundary. Manohar Ray. *Phil. Mag.* **28**, 231–40(1939).—Math. E. J. Rosenbaum

Viscosity of liquids at high hydrostatic pressures. R. B. Dow. *Phil. Mag.* **28**, 403–22(1939).—High-pressure viscometry is discussed with reference to both abs. and relative methods. A concentric-cylinder viscometer is described which can be used up to 3000 kg./sq. cm. The results obtained with a Pennsylvania extd. oil agree with those found with a rolling-ball method. Bridgman's falling-ball viscometer was used to obtain viscosity coeffs. for 6 CS_2–CCl_4 mixts. at 30° and at 75° up to a pressure of 10,000 kg./sq. cm. Viscosity is not a simple function of the concn. of the components. There is no indication that the degree of mol. interlocking suddenly changes either with temp. or with pressure. The thermodynamic aspects of high pressures are considered and the deficiencies of known equations of state are pointed out. There is a part of the energy of viscous flow which cannot be measured by thermodynamic quantities and for which there is no adequate theory. E. J. Rosenbaum

Viscosity of nonideal binary liquid systems. M. K. Srinivasan. *J. Indian Chem. Soc.* **16**, 305–7(1939); cf. *C. A.* **32**, 8886[5].—A modification of the cube-root equation of Kendall and Monroe (*C. A.* **11**, 2850), in which $\eta^{1/3} = (\rho_o/100)(n_1{}^{1/3}\nu_1 + n_2{}^{1/3}\nu_2)(\rho_o/\rho_c)^m$, (where n, n_1 and n_2 are viscosities of the mixt. and pure components, ν_1 and ν_2, vols. of pure components in 100 g. of mixt., ρ_o the observed d. of the mixt., ρ_c the d. calcd. from the formula $100/(\nu_1 + \nu_2)$, and m is a const.) is approx. as satisfactory as the equation of Macleod (*C. A.* **17**, 1909, 2072, 2211) and that of Spells (*C. A.* **30**, 4063[6]) for the calcn. of the viscosities of mixts. composed of picoline-water, pyridine-water, lutidine-EtOH, pyridine-C_6H_6, pyridine-EtOH, MeOH-Et_2O, EtOH-phenetole, phenol-aniline, phenol-acetone, EtOH-water and HOAc-water, resp. George Ayers

Problems in mathematical crystallography. N. Nowacki. *Mitt. naturforsch. Ges. Bern* [*Sitzber.*] **1938**, 51–2(1939). W. C. Tobie

Crystal chemistry of nonmetallic inorganic substances. 1 M. F. Machatschki. *Naturwissenschaften* **27**, 685–93 (1939); cf. *C. A.* **32**, 5274[2].—A review with numerous references on the 1937–38 developments in knowledge of crystal structure: complex silicates, phosphates, arsenates, borates, sulfates, antimonates, aluminates, tungstates, halides, cyanides, etc. B. J. C. van der Hoeven

Density and compressibility of solid hydrogen and deuterium at 4.2°K. Helen D. Megaw. *Phil. Mag.* **28**, 129–47(1939).—A pycnometer method was used to 2 obtain d. values at the b. p. of H and at pressures up to 100 atm. At zero pressure d. is 0.0890 ± .0004 g./cc. for H and 0.2059 ± .0010 for D. The av. compressibility in the pressure range 0–100 atm. is 5.0×10^{-4} sq. cm$_t$/kg. for H and 3.3×10^{-4} for D. Grüneisen's law is not valid for these substances, probably because their zero-point energy is relatively very high. E. J. Rosenbaum

The polymorphism of Cu_2S and the relations between the solid phases in the system Cu_2S–CuS. Newton W. 3 Buerger. *J. Chem. Phys.* **7**, 1067–8(1939).—The phase diagram of the system contains 3 compds. (and 6 phases) from 30 to 250°. chalcocite, Cu_2S; digenite, Cu_9S_5; and covellite, CuS. Chalcocite above 105° has a nonisometric completely disordered basic structure; 78–105°, a non-isometric partially disordered basic structure; 52–78°, a nonisometric ordered basic structure; and below 52°, an orthorhombic superstructure. The superstructure phase can dissolve 8 at. % CuS; the ordered basic structure, 2 at. %. Soln. occurs by omission of Cu from CuS structures. Above 47° digenite dissolves Cu_2S or CuS. The orthorhombic-cubic modification of chalcocite reported at 91° was not found. G. M. Petty

Isotope effect in potassium dihydrogen phosphate. A. R. Ubbelohde and I. Woodward. *Nature* **144**, 632 (1939).—KH_2PO_4 and KD_2PO_4 have different crystal 5 structures. KD_2PO_4 is monoclinic; there are 8 mols. per unit cell, $a = 7.37 \pm 0.01$ A., $b = 14.73 \pm 0.01$ A., $c = 7.17 \pm 0.01$ A.; $\beta = 92.0°$. The crystals elongate along the c axis: (100), (010) and (110) are prominent faces. There is a considerable expansion of the lattice when D is substituted for H. G. M. Petty

Gas flow in solids. R. M. Barrer. *Phil. Mag.* **28**, 148–62(1939).—Math. Solutions of the diffusion equation are obtained for the case of diffusion accompanied 6 by phase-boundary processes such as transfer from the gas phase (or an adsorbed layer) into the solid or the reverse process. Both steady and nonsteady states of flow are considered. There can be a large effect of surface process on the permeability and a large concn. discontinuity at surfaces. E. J. Rosenbaum

Permeability of metal membranes to diatomic gases. R. M. Barrer. *Phil. Mag.* **28**, 353–8(1939); cf. preceding abstr.—The permeation rate was calcd. by assuming 7 various processes at interfaces. The flow of gas through a metal can never be infinite whatever the pressure and whatever mechanisms are assumed. If large concn. discontinuities occur at the boundaries of the metal, the permeation rate, even at high pressures, is proportional to the sq. root of the pressure. E. J. Rosenbaum

Effect of surface oxides on the sorptive properties of active charcoal with respect to substances in the vapor state. E. D. Zaverina and M. Dubinin. *J. Phys. Chem.* (U. S. S. R.) **13**, 151–62(1939).—From exptl. data 8 on the adsorption of vapor-phase benzene, pentane, heptane and MeOH and aq. HCl, NaOH, H_2SO_4, formic, acetic, propionic and valeric acids, phenol, methylene blue and Congo red on fine sugar charcoals variously activated in CO_2, air or in vacuum at 350 to 1000° for 1–110 hrs., it is found that the addnl. oxidative activation produces considerable changes in porosity, so that theoretical conclusions based upon direct comparison of the isotherms before and after activation are not permissible. The adsorption potentials of the vapor-phase nonpolar substances calcd. from the adsorption isotherms are independent of the nature of the surface oxides on the charcoal; for polar vapors, the potentials are greater for more polar acidic surfaces. F. H. Rathmann

Exchange adsorption on colloidal titanium dioxide. V. A. Kargin and M. Tolstaya. *J. Phys. Chem.* (U. S. S. R.) 9

13, 211–15(1939).—Exptl. data on the adsorption of H_2SO_4, Na_2SO_4 and NaOH on a TiO_2 soln. obtained by hydrolysis of $TiCl_4$ and partial dialysis are given. For sols with a low Cl^- content, the adsorption of SO_4^{--} with respect to the pH is given by the usual adsorption isotherm; for large concns. of Cl^-, the adsorption isotherm becomes S-shaped, as with iron oxides. Cf. K. and Klimovitskaya, *C. A.* **33**, 4105[1]. F. H. Rathmann

Adsorptive properties of synthetic resins. III. S. S. Bhatnagar, A. N. Kapur and Mahendra Sarup Bhatnagar *J. Indian Chem. Soc.* **16**, 261–8(1939); cf. *C. A.* **33**, 8077[8].—Adsorption of acids by acid-catalyzed phenol-formaldehyde resin (I) or by acid-catalyzed resorcinol-formaldehyde resin (II) increased in the order: HCOOH, CH_3COOH, butyric acid. With NH_3-catalyzed phenol-formaldehyde resin (III), NH_3-catalyzed resorcinol-formaldehyde resin (IV), or *m*-phenylenediamine-formaldehyde resin (V), the above order was reversed. Refluxing IV with HCl did not change the order of adsorption of acids from that of the untreated resin. The differences in adsorption by acid- and alkali-condensed resins are probably due to the inner ultrapores of the latter. Adsorption of HCOOH, CH_3COOH, $CH_3(CH_2)_2COOH$, $(COOH)_2$, $CH_2(COOH)_2$, $(CH_2COOH)_2$, $HOOC(CH_2)_4COOH$, $ClCH_2COOH$, $Cl_2CHCOOH$, Cl_3CCOOH, $PhCH_2COOH$, $CNCH_2COOH$, NH_2CH_2COOH, and $HOCH_2COOH$ by V follows the same general order as the ionization consts. at 25°, except with $HOCH_2COOH$, where the HO-group depresses the adsorption. The same generalization can be made for the adsorption of the first 6 acids named above by III. The introduction of acidic groups into acids increases adsorption by V, whereas the introduction of basic groups decreases it. George Ayers

Electrolyte adsorption and activity coefficient. III. Adsorption of neutral salts. (1.) Wolfgang Ostwald. *Kolloid-Z.* **88**, 144–61(1939); cf. *C. A.* **33**, 7170[4].—Exptl. data of various workers for the adsorption of neutral salts on charcoal of different kinds and electrolyte content, and on MnO_2 gel and washed $Al(OH)_3$ were examd. to see whether they can be represented by the equation $f_x = af_{x,2} = b$ previously found to hold for the adsorption of strong acids on charcoal. f_x is the activity coeff. for the virtual concn. of the soln. being adsorbed, $f_{x,2}$ is the activity coeff. of the equil. soln. and a and b are numerical consts. Excellent agreement was found for salts of the types (1-1), (1_2-2), (2-1_2), (1-4) and (3-1_2) for all 3 adsorbents. The data found for multivalent ions are often much too high to agree with the phys. activity theory. As in the case of acids, only strong electrolytes conform to the new activity-coeff. equation. CdI_2 gives a systematically bent line of the same type as that for AcOH. In MeOH the curves for CdI_2 and AcOH approach that for a strong electrolyte. The new activity coeff. equation makes possible a quant. characterization of the adsorption activity of strong electrolytes. The steepness of the concn. function of the adsorption is characterized by the value of the multiplicative function a. The concn. function is symbatic with a. The abs. amt. of the adsorption is characterized by the size of the const. b. The abs. amt. of adsorption varies antibatically with the value of b. With an actively adsorbed substance such as $A_1(CNS)_3$, a has a large value and b has a small value. For the most active adsorption a should be as large as possible and b as small as possible. Felix Saunders

Comparison of the adsorption, electrolytic and interference methods of measuring film areas. F. H. Constable. *Nature* **144**, 630(1939).—The methods are compared with actual measurements on Ni, Cu and oxidized Cu surfaces. G. M. Petty

New method for determining the rate of diffusion of surface-active molecules on the solid-gas boundary surface. P. F. Pokhil. *J. Phys. Chem.* (U. S. S. R.) **13**, 146(1939).—A method is described based on two-dimensional evapn. of a surface-active substance and readsorption as a film measured by an Adams balance. F. H. Rathmann

Electrical characteristics of molecular films. Francis J. Norton. *J. Am. Chem. Soc.* **61**, 3162–8(1939).—Surface potentials can be put on *X* or *Y* stearate multi-films by applying a voltage while the films are in a conducting medium, as air ionized by Po. The films lose their charge exponentially when the voltage is off. The coulombs represented by the area under the automatically registered discharge curve agree with Langmuir's equation which calcs. potentials resulting from surface charges. Surface potentials exist on Ca stearate *X* films deposited on glass. A. B. Garrett

Mechanical properties of unimolecular layer films on a liquid-liquid boundary. P. F. Pokhil. *J. Phys. Chem.* (U. S. S. R.) **13**, 301(1939).—By means of a rotating-disk method, the strength of myristic and palmitic acid films on the boundary water-kerosene or water-benzine was found to be practically the same as one on a water-air boundary, i. e., ~10 dynes/cm. F. H. Rathmann

A new technique for the spreading of proteins and the "spreading number." D. Dervichian. *Nature* **144**, 629–30(1939); cf. *C. A.* **33**, 7171[6].—When a protein is dissolved in H_2O to which a trace of a capillary-active substance able to lower the surface tension is added, the protein can be spread on the surface of an aq. soln. The meaning of the "spreading number" is discussed. E. D. Walter

Electrocapillary curves of very dilute amalgams. T. Erdey-Grúz and O. Bajor. *Z. Elektrochem.* **45**, 707–12 (1939).—At concns. of less than 10^{-5} g. at./l. of amalgams of Zn, Cd, Tl, Pb, Sn, Bi and Cu the electrocapillary curves, detd. by the drop-wt. method, almost coincide with those of pure Hg. From 10^{-5} to 10^{-4} (10^{-3} for Pb) g. at./l. the surface-tension max. is raised and moved toward more neg. potentials; the shift of potential is generally greater the more noble the metal. The anions in soln. have an appreciable effect with Zn, but with increasing nobility of the dissolved metal this effect is less marked. With Bi and Cu amalgams the position of the potential max. is the same in KI and K_2SO_4 solns. A double layer, involving dissolved metal on the amalgam side and ions on the soln. side of the interface, is apparently set up; the mutual effect of the 2 layers is greatest with Zn and least with the nobler metals. S. Glasstone

Electrical double layer at the interface of two liquids. E. J. W. Verwey and K. F. Niessen. *Phil. Mag.* **28**, 435–46(1939).—Theoretical. A general equation for the potential function in both phases is derived and the partition of the potential drop is considered. The largest part of the potential drop occurs in the phase where the product of ionic concn. and dielec. const. has the smaller value. A very unequal distribution of the potential drop does not necessarily imply that either the thickness of the diffuse layers or the charge ds. on each side of the interface are very different. E. J. Roseribaum

Surface tension and angle of contact of mercury in vacuo. A. E. Bate. *Phil. Mag.* **28**, 252–5(1939).—The angle of contact between Hg and glass is 90°. The surface tension is 490 dynes/cm. at 20°. E. J. R.

Wettability of solid substances as a characteristic of the molecular nature of their surfaces and a new method for its measurement. Z. V. Volkova. *J. Phys. Chem.* (U. S. S. R.) **13**, 224–39(1939).—The method requires considerable calcn., depends on the construction of the curve of the meridian sections of the drops and bubbles and is applicable to bubbles for θ less than 90° and to drops for θ greater than 90°. Exptl. data on talc agree with those found by the method of Meck, and the new method is still applicable to small angles of contact. F. H. Rathmann

Surface activity of hydrophilic colloids. K. F. Zhigach and P. A. Rebinder. *J. Phys. Chem.* (U. S. S. R.) **13**, 94–105(1939).—Exptl. data on the formation of surface layers in gelatin, albumin, saponin, tragacanth, starch and agar-agar sols at 20 and 35° are given in the form of surface-tension-time, σ-τ, curves. The $\log(\sigma_t - \tau_\infty)$ - τ functions for albumin are linear for concns. from 0.05 to 4.0%. The velocity consts. for the unimol. reactions vary with the temp. and with the colloid concn. F. H. R.

New method of absorption of aerosols and gases by liquids. G. P. Luchinskii. *J. Phys. Chem.* (U. S. S. R.)

13, 302(1939).—Difficultly absorbed aerosols and gases such as MgO, ZnO, P_2O_5, H_2SO_4 fumes, NO, NO_2, SO_3, etc., are rapidly absorbed by foams produced by addn. of various surface-active substances to the absorbing liquid. F. H. Rathmann

Method of determining the hiding power of artificial fogs and smokes. Celestino Ficai. *Atti XXVII riunione, Bologna, Soc. ital. progresso sci.* 5, 331–45(1939).—An app. is described utilizing a photoelec. cell and an internal camera for measuring the relative transmissions of light through artificial fogs and smokes as well as their diffusion and "dulling" (ability to prevent photography) powers. Measurements are tabulated for 27 substances or combinations commonly used for the production of artificial smokes. The effect of relative humidity of the air on the hiding power is also discussed. H. A. Fromani

A new electro-optical effect. Hans Mueller and B. W. Sakmann. *Phys. Rev.* 56, 615–16(1939); cf. *C. A.* 33, 3656[8], 6115[5].—The electro-optical birefringence was detd. as a function of field strength (0–150 v./cm.) and of frequency (60, 100, 200, 500 and 15,000 ~) in a monodisperse bentonite sol. The data are discussed. G. M. Petty

Effect of freezing on colloid structure formation of basic aluminum salts. E. I. Kvyat. *J. Phys. Chem.* (U. S. S. R.) 12, 634–8(1938).—Basic Al salt sols were obtained by peptizing freshly pptd. $Al(OH)_3$ with 0.05 *N* HCl and 0.5 *N* CH_3COOH at 100°. During freezing, the resulting increased concn. of the electrolyte in the micelle always produces coagulation of the sols. The viscosity may increase owing to structure formation or decrease owing to transformation from an extended to a compact structure Dialysis or addn. of electrolyte (0.005–0.02 *N* K_2SO_4) decreases the stability of the sols, leading to compact structure formation or eventually to pptn. On remelting, either pptn. or reformation of the sols takes place, but the new gelatinization process is less intense. **Effect of freezing on structure formation in colloidal basic iron salts.** *Ibid.* 660–7.—The viscosity of gels of basic ferric chloride and phosphate alone increases up to 5-fold on freezing; after longer freezing coagulation again leads to a decrease in η. Addn. of electrolytes (K_2SO_4) before freezing fosters formation of a compact structure and decreased values of η. These processes are partially reversible on thawing of the frozen gels. F. H. Rathmann

Solubility of compounds of high molecular weight. V. General characteristics of solutions of compounds of high molecular weight. V. A. Kargin, S. Papkov and Z. A. Rogovin. *J. Phys. Chem.* (U. S. S. R.) 13, 206–10 (1939).—General discussion. F. H. Rathmann

The disintegration of macromolecules by ultrasonic waves. G. Schmid and O. Rommel. *Z. Elektrochem.* 45, 659–61(1939).—The viscosities of solns. of polystyrenes in PhMe are diminished by the continued application of ultrasonic waves; this is attributed to a decrease in mol. wt. of the polymers. Cessation of the waves is accompanied by a relatively small increase in viscosity. The mol. wts., detd. by the Staudinger viscosity method, of 3 fractions with original values of 850,000, 350,000 and 195,000, resp., fall to a limiting value of approx. 30,000 in 2 hrs. The longer mols. are more rapidly disintegrated than are the short ones. Increase of external pressure, up to 15 atms., tends to diminish the depolymerization to some extent. It is considered that the ultrasonic waves are able to break mechanically the C—C bonds in the thread-like mols. when they exceed a certain min. length. S. Glasstone

The viscosity of dilute solutions of long-chain molecules. III. The Staudinger viscosity law. Maurice L. Huggins. *J. Applied Phys.* 10, 700–4(1939); cf. *C. A.* 33, 4848[8].—H.'s theoretical equations, applied to dil. solns. of "randomly kinked" long-chain mols., reduce to the same form as Staudinger's empirical law $\eta_{sp} = k_s nc$ (n is chain length, c concn. of unit groups in the soln., k_s a const. for each type of chain). The effect of the approximations made in deriving the equation is discussed, and it is concluded that they will not appreciably affect the form of the equation, only the effective magnitude of the various theoretical consts. being uncertain. A. O. Allen

Equilibrium between molecularly dispersed and colloidal substances in aqueous soap solutions. II. Temperature dependency of the equilibrium and the solubility curve of soaps. Joachim Stauff. *Z. physik. Chem.* A185, 45–59(1939); cf. *C. A.* 33, 4521.—The hydrolysis curves of Na palmitate between 25° and 90° were detd. in the region 0.0005 to 0.1 mol. A sharp break occurs at a "critical concn." which is taken as a characteristic quantity for the equil. between a colloidal and a molecularly dispersed system. With increasing temp. the equil. is displaced toward mol. dispersion. By detg. the sepn. and the soln.-temps. of Na palmitate solns. of different concns., a soly. curve can be drawn up to concns. of 1 mol./l. The abnormal form of the soly. curve is attributed to the effect of the equil. between colloidal and molecularly dispersed substances. The activity coeff. of the Na ion of Na palmitate solns. of different concns. is deduced. Na stearate and Na myristate solns. are also discussed. Victor R. Deitz

Viscosity relations of aqueous solutions of sodium oleate and various phenols. Ralph G. D. Moore. *J. Am. Chem. Soc.* 61, 2990–5(1939).—The maxima previously observed (cf. *C. A.* 26, 5813; 32, 4046[6]) in the viscosity of Na oleate–phenol–water systems were checked qualitatively but not quantitatively with more rigorously purified Na oleate. Not all phenolic substances produce such maxima. Evidence is adduced that the formation of acid soaps is a minor cause of the observed maxima in viscosity. A. B. Garrett

Solutions of the paraffin-chain sulfonic acids as colloidal electrolytes. Evelyn Laing McBain, Walter R. Dye and Stewart A. Johnston. *J. Am. Chem. Soc.* 61, 3210–16 (1939).—Data are presented for the d., n and elec. cond. of the homologous series of straight-chain sulfonic acids from 2 to 14 C atoms. The data show the gradual transition from the behavior of fully dissocd. electrolytes for the lowest homologs through the intermediate members in higher concn. to the typical behavior of colloidal electrolytes for the higher homologs. The latter approximate complete dissocn. in extreme dilns.; they rather suddenly lose much of their cond. through assocn. of ion-pairs and ions to form colloidal particles of low cond. This interpretation is in agreement with exact f.-p. and diffusion data for dodecylsulfonic acid. A. B. Garrett

Aging phenomena and the molecular size of chain complexes in solution. Wilhelm Wehr. *Kolloid-Z.* 88, 290–318(1939); cf. *C. A.* 33, 9685[1].—The reduction of viscosity of chain complexes, such as condensation polymers (cellulose derivs.), unsatd. vinyl polymers (rubber), and satd. vinyl polymers (polymerized vinyl acetate, polystyrenes, etc.) with age depends on the structure of these complexes. Decompn. of the cellulose derivs. and rubber can be observed at temps. up to 60° in the presence of air, and that of the satd. vinyl polymers in the presence of active O (peroxides). Antioxidants tend to stabilize condensation complexes, such as nitrocellulose, by inhibiting their oxidative decompn.; with polystyrenes, however, high concns. of antioxidants causes rupture of the chain, although lower concns. tend to stabilize the polystyrene by decreasing the effect of the peroxide. The mech. properties of nitrocellulose film increase with increased chain length of the mol. Viscosity tests on denitrated products of nitrocellulose show that the nitrocellulose is built up of reticular rather than simple chain complexes. On the other hand, titration of the end groups of the α-cellulose of the denitrated product indicates only half as large a mol. wt. of the complex. A probable explanation of this apparent discrepancy is given. Ninety-one references. S. I. Aronovsky

The relation between the refractivity of crystalline cellulose and the temperature. A. Frey-Wyssling and K. Wuhrmann. *Helv. Chim. Acta* 22, 981–8(1939).—The refractivity of liquids is more dependent upon the temp. (by approx. a power of 10) than is that of cryst. compds. This remarkable difference in the sensitivity may be correlated with the nature of the bond forces that give their cohesion to the various phases. While in a liquid the coherence of the mols. is caused by van der Waals cohesion

forces, the cohesion in cryst. lattices is due to valency forces 10 times as great. This large difference of the bond forces holds only when the main valency or ion lattices are chosen for comparison. With the mol. lattices of org. compds. the binding forces are of the type of van der Waals cohesion forces as with liquids. It is therefore to be expected that the *ns* of org. mol. lattices are more affected by a change of temp. than those of inorg. crystals. In chain lattices main valency forces act along the chain axis whereas van der Waals forces are active at right angles to it. Chain lattices should therefore occupy an intermediate position with regard to their optical sensitivity toward temp. While the lateral displacement of the chain mols. with changing temps. is quite plausible, only small changes in dimension are possible in the chain direction. In cellulose chemistry, the question is open to discussion (cf. Mark, *C. A.* **33**, 1925[4]) whether the chain mols. are linked together here and there by main valency cross-linkages as, e. g., by O-bridges. Such cross-bridges may explain the limited capability of swelling and the insoly. of cellulose. A large no. of such cross-bridges would then mean that not a chain lattice but a main valency lattice is present in cellulose and the latter should have similar sensitivity to temp. changes as compds. with main valency lattices. With these considerations in mind, the dependence of the 2 main *ns*, of the double refraction, of the dispersion and of the dispersion of the double refraction of cryst. cellulose from ramie fibers upon the temp. were detd. at 0°, 20° and 50°, with Becke's method. Cryst. cellulose occupies an intermediate position between solid and liquid substances as far as the change of the temp. of its refractivity and its thermal expansion are concerned. This supports a chain lattice structure for bast fibers. It indicates that no noteworthy main valency, like cross-linkages, are present between the cellulose thread mols., as otherwise they would more likely behave like solid substances with main valency lattices. The presence of main valency cross-linkages of cellulose mols. in the cell walls is not disputed for they may be destroyed during the isolation and bleaching of the ramie fibers. They are, however, no longer present in the isolated ramie fiber, since the latter swells and even dissolves in concd. $ZnCl_2$ soln. while untreated cell walls do not. F. L. Brauns

Chemical reactions between electrolytes and proteins in the form of sols or gels. I. Introduction. E. J. Bigwood. *Bull. soc. chim. biol.* **21**, 922–35(1939).—The structure of the protein mol. is discussed. **II. Reactions with salts of the alkali metals, especially chlorides and sulfates of sodium and potassium. Methods.** *Ibid.* 936–45.—Methods of detg. Na, K, Cl and SO_4 ions fixed by proteins are described. **III. Experimental results.** *Ibid.* 946–58.—The chlorides and sulfates of Na and K were added to protein soln. or placed in contact with loose fragments of gelatin gel and the amts. of each ion fixed by the protein at several levels of pH detd. The results are in accordance with the Donnan equil. rule. L. E. Gilson

Effect of neutral salts on the position of the isoelectric point. A. Pasynskii and I. Petrov. *J. Phys. Chem.* (U. S. S. R.) **12**, 556–68(1938).—A cataphoretic method without the use of a buffer is described. The isoelec. point of gelatin lies at pH 5.06 in H_2O, 5.38 in 0.02 *M* and 5.10 in 0.06 *M* $BaCl_2$; 4.90 in 0.005 *M* and 4.95 in 0.01 *M* KCNS. Data for KCl, KI, Ag_2SO_4, $BaCl_2$, KCNS and citrate-phosphate buffer are given. The mechanism of adsorption of neutral salts on gelatin is discussed. **Effect of concentration of gelatin on the position of the isoelectric point.** *Ibid.* 569–73.—From exptl. data on cataphoresis of gelatin sols over the range of concn. 0.2 to 1.0% gelatin, there is no justification for the belief that the isoelec. point varies with the concn. of the protein studied. Cf. *C. A.* **33**, 4279[8]. F. H. Rathmann

Electrolysis and electroösmosis in gelatin. Jean Swyngedauw. *Kolloid-Z.* **88**, 318–28(1939); cf. *C. A.* **33**, 2393[9], 3658[8].—A systematic investigation of the electrolysis of gelatin gels is discussed. The results indicate that the isoelec.-point of gelatin is at pH 4.8. A simple elec. process for the prepn. of isoelec. gelatin by electrolysis is described. Exptl. investigation of electroösmosis shows that the Helmholz formula for this phenomenon is incorrect. The exptl. facts can be explained more correctly by the transport of water of hydration. The quantity of water transported by each ion varies, on diln. of the gelatin gel, from a few mols. for a 25% gelatin soln. to many thousand mols. for a 1.7% soln. S. I. A.

Equilibrium between a liquid and a gas at high pressures and temperatures. IV. Solubility of air in water and in sodium hydroxide solutions of various concentrations. M. I. Levina and N. P. Stsibarovskaya. *J. Phys. Chem.* (U. S. S. R.) **12**, 653–9(1939); cf. *C. A.* **32**, 4758[4].—Data are given on the soly. of O_2, N_2 and air in H_2O, and in 0.5, 2.0 and 4.0 *N* solns. of NaOH at 100 kg./sq. cm. pressure and at temps. from 0 to 240°. The soly. is a min. at 75° for both N_2 and O_2 in H_2O and at 35–50° in 4 *N* NaOH. The soly. of O_2 in strong alkali decreases 7-fold at 0°, 4-fold at 240°; of N_2, 7 and 3.5-fold with respect to the soly. in pure H_2O. The ratio $N_2:O_2$ is 2.0 at 0°, and increases from 3.0 to 3.8 with increasing concn. of NaOH at 240°. Exptl. data are given. F. H. R.

Solubility of sodium chloride in mixtures of hydrogen and deuterium oxides. Tsing-Lien Chang and Tsin-Chang Chu. *Z. physik. Chem.* **A184**, 411–15(1939).—The soly. of NaCl at 25° was detd. in H_2O-D_2O mixts. and is given with an accuracy of ±0.1% by the linear expression: $s_n = 6.145 - 0.334\,n$, where s_n is equal to the no. of mols. NaCl that are dissolved in 55.51 mols. of a water mixt. and *n* is the mol. fraction of D_2O. The D_2O that was used had $d_4^{25°} = 1.10496$. V. R. Deitz

Parachor of aluminum bromide in benzene. Isidore Poppick and Alexander Lehrman. *J. Am. Chem. Soc.* **61**, 3237–8(1939).—An attempt was made to det. whether the mol. formula of $AlBr_3$ in C_6H_6 is the same as that detd. for the molten salt (Sugden, *C. A.* **23**, 2423). The mean *P* for Al_2Br_6 in C_6H_6 is 206.6 (mole fraction 0.01737) to 238.3 (mole fraction 0.08325); more concd. solns. could not be used because of the sepn. of a dense, light-red oil. Extrapolation to a mole concn. of 1 gives a value of *P* of 470.4, which corresponds fairly well with S.'s value of 457.6 for molten Al_2Br_6 when the large range of extrapolation is considered. The results tend to indicate that the formula of the salt in C_6H_6 is the same as that for the molten compd. C. J. West

Dispersion and absorption of electric waves in alcohol and aqueous solutions. Karl E. Slevogt. *Ann. Physik* **36**, 141–65(1939).—A transposed audiofrequency bridge was employed that allowed the use of a wire compensating resistance and the usual grounding. A method is described for detg. the dielec. const. for conducting liquids in short-wave regions. During the course of the study a new method was developed for measuring the abs. values of the dielec. const. and absorption coeff. This method was applied to the study of water and aq. solns. of gelatin (1.375%), levulose (78%), cane sugar (30, 50, 65%), acetone (0, 25, 50, 66.9, 100%) and KCl (0.03 *N*), and MeOH, EtOH, PrOH, BuOH and iso-AmOH. Water and the alcs. showed good agreement, but the sugar solns. showed no agreement with the Debye theory. S. L. Gerhard

The viscosity of solutions in chloroform. Amando Clemente and Pedro Gabriel. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 5–18(1939).—Viscosity data at 27–29° on the binary systems MeOH–$CHCl_3$, BuOH–$CHCl_3$, PrOH–$CHCl_3$, EtOAc–$CHCl_3$ and *m*-xylene–$CHCl_3$ indicate the formation of the assocd. mols.: $3MeOH.CHCl_3$, $MeOH.CHCl_3$, $4PrOH.CHCl_3$, $EtOAc.9CHCl_3$, $19C_6H_4Me_2.CHCl_3$, $3C_6H_4Me_2.2CHCl_3$ and $3C_6H_4Me_2.7CHCl_3$. The formation of these assocd. mols. is indicated either by a max. in the viscosity curve, a min. in the fluidity curve, or by the max. decrease in fluidity. George Ayers

Viscosity of mixtures of aqueous solutions of strong electrolytes, as related to the theory of Onsager and Fuoss. Erik Asmus. *Ann. Physik* **36**, 166–82(1939); cf. *C. A.* **33**, 5728[8].—Mixts. of $CuSO_4$ and KCl and of

$CuSO_4$ and H_2SO_4 were studied as a function of the mol. concn. and the total ion concn. For great diln. the relative viscosity of a mixt. of 2 strong electrolytes obeys the relation $\eta/\eta_0 = 1 + a\sqrt{\Gamma} + b\Gamma$. Within the limits of error there was good agreement between the theoretical and exptl. values obtained for the coeff. a. There appears to be no simple mixt. rule for detg. b. S. L. Gerhard

Osmotic pressure. Hermann Frahm. *Z. physik. Chem.* **A184**, 399–410(1939).—From the Maxwell-Boltzmann energy-distribution law there is derived the general of the lowering of vapor pressure and of the osmotic pressure of solns. The laws of Raoult and van't Hoff are found in the thermal energy exchange between solute and solvent mols., while the deviations from these laws are attributed to specific mol. forces. Two examples are considered: NaCl in water and EtOH in water. Victor R. Deitz

Thermodynamic properties of dilute solutions of non-electrolytes. Seizi Kaneko. *J. Chem. Soc. Japan* **60**, 763 8(1939).—Math. T. Katsurai

The electrical conductivity of uni-univalent salts in acetone. J. F. J. Dippy, H. O. Jenkins and J. G. Page. *J. Chem. Soc.* **1939**, 1386–91.—Measurements were made on acetone solns. of KI, NaI, $AgNO_3$, Na and K salicylate, LiBr and NH_4I. The first 2 of these salts are highly dissocd., the cond. attaining the Onsager theoretical values at high dilns.; the next 3 are largely assocd., cond. changing with concn. approx. as predicted by the mass-action law; the last 2 show intermediate behavior. A. O. A.

Triple ions and transference numbers. Malcolm Dole. *Trans. Electrochem. Soc.* **77**, 10 pp.(preprint)(1940).—The effect of the formation of triple ions on the variation of transference no. with change of concn. is discussed and the theoretical equations derived are tested by means of the recent data of Lanning and Davidson (*C. A.* **33**, 1574[2]) on the transference nos. of acetates in anhyd. AcOH. In the triple-ion theory of Fuoss and Kraus (*C. A.* **27**, 5233) it was assumed that the triple neg. ion $(- + -)$ and the triple pos. ion $(+ - +)$ were both formed to the same extent, an assumption which was introduced to explain the min. in cond. data. Conclusion: The data of L. and D. do not necessarily invalidate the hypothesis of equal concns. of pos. and neg. triple ions as made by Fuoss and Kraus. C. G. F.

Transference numbers and diffusion potentials in fused salt mixtures. Karl E. Schwarz. *Z. Elektrochem.* **45**, 740–3(1939); cf. *C. A.* **27**, 5007; **30**, 359[5]. A theoretical treatment of diffusion and transference in fused salt mixts. The following topics are considered: the transference no. of an ion; the opposing effects of transference and diffusion; the diffusion potential; the sign of the transfer; and the significance of transference in liquid metal–fused salt systems. Equations are derived for the ratio of the concns. at anode and cathode and for diffusion potential. S. Glasstone

Properties of electrolytes in mixtures of water and organic solvents. IV. Transference numbers of hydrochloric acid in water and dioxane–water mixtures from 0 to 50°. Herbert S. Harned and Edwin C. Dreby. *J. Am. Chem. Soc.* **61**, 3113–20(1939); cf. *C. A.* **33**, 9095[6,8].—The cation transference number was detd. from data on the e. m. f. of cells of the type Ag-AgCl|HCl (m), dioxane (X), H_2O (Y)|HCl (r), dioxane (X), H_2O, (Y)|AgCl-Ag and from data on cells without liquid junction (cf. *C. A.* **32**, 3240[3]). The limiting transference no. was detd. by extrapolation. Agreement with the limiting law of the Onsager conductance theory was observed in the water, 20, 45 and 70% dioxane-water mixts. A. B. Garrett

The dissociation constants of some nitrophenols in deuterium oxide. D. C. Martin and J. A. V. Butler. *J. Chem. Soc.* **1939**, 1366–9.—The ratio K_h/K_d of the dissocn. consts. in H_2O and D_2O was detd. for 2,6-, 2,5-, 2,4- and 3,5-dinitrophenol and for *o*- and *p*-nitrophenol by comparing spectrophotometrically the extent of dissocn. of the compds. in appropriate acetate or phosphate buffer solns. in light and heavy water. The values of the ratio increase as K_h decreases and lie close to the curve given by Rule and LaMer (*C. A.* **32**, 7328[2]). A. O. Allen

The second ionization constant of oxalic acid from 0 to 50°. Herbert S. Harned and Leslie D. Fallon. *J. Am. Chem. Soc.* **61**, 3111–13(1939).—The ionization const. of $HC_2O_4^-$ was detd. at 5° intervals from the e. m. f. data of the cells $H_2|NaHC_2O_4$ (xm_1), $Na_2C_2O_4$ (xm_2), NaCl (xm_3)|AgCl-Ag. Values of the heat content and heat capacity of the ionization reaction are tabulated. A. B. Garrett

The activity of water in sulfuric acid solutions at 25° by the isopiestic method. H. Sheffer, A. A. Janis and J. B. Ferguson. *Can. J. Research* **17**, B, 336–40(1939); cf. *C. A.* **33**, 8476[5].—The activities of water in aq. solns. of NaCl and of H_2SO_4 were compared by the isopiestic method at 25° over a range of molalities extending up to that of the satd. salt soln. The app., which was of the Sinclair type, proved to be an efficient as any yet devised. The results remove the uncertainties that previously existed in regard to the position of the m_1/m_2 curve and give a qual. indication of the second dissocn. of H_2SO_4. The calcd. activities agree with the best available data. The isopiestic standard chosen by Janis and Ferguson (cf. *C. A.* **33**, 8476[5]) was confirmed over the whole molality range. J. W. Shipley

Activity coefficients in concentrated aqueous solutions of strong electrolytes described by a formula containing the mean ionic diameter as single parameter. I. Theory and application to the alkali chlorides, bromides and iodides. Pierre Van Rysselberghe and Sylvan Eisenberg. *J. Am. Chem. Soc.* **61**, 3030–7(1939).—The activity coeff. is represented by a one-parameter formula in which the Debye-Huckel term and the van der Waals term are represented in terms of the mean ionic diam., a. The resulting formula is then applied to a systematic interpretation of the activity data of the alk. chlorides, bromides and iodides with remarkable success. A set of mean ionic diams. is obtained and various remarks as to the extent of hydration and penetration of ions at contact are derived from a comparison of these diams. with the sums of the standard cryst. radii. Calcd. activity coeffs. agree well with exptl. values. A. B. Garrett

The dissociation of multivalent, macromolecular acids. Werner Kern. *Biochem. Z.* **301**, 338 56(1939); cf. *C. A.* **32**, 4048[6], 8243[1].—The neutralization curves of polybasic acids can be represented by an extension of the dissocn. equation of Michaelis (*C. A.* **14**, 3178). Macromol., multivalent acids can be characterized by 2 consts., the titration exponent and the mean titration const. The validity of the deductions is shown by potentiometric measurements, with H_2 or quinhydrone electrodes, during the neutralization of synthetic multivalent acids, e. g., polyacrylic and polymethylacrylic acids and natural multivalent acids, e. g., polynucleic acids and those of gum arabic and of agar. The H-ion buffering in solns. of multivalent acids is considered. S. Glasstone

Activity of urea in aqueous solutions. A. I. Krasil'shchikov and S. S. Trainina. *J. Phys. Chem.* (U. S. S. R.) **13**, 281–5(1939).—By use of various exptl. data on the vapor pressure and the heats of diln. of urea solns., the activity coeffs. are calcd. from 25 to 90°. At 25°, the ratio a_2/N_2 has the values 1.0 for $N = 0$; 0.995 for 0.002; 0.973 for 0.010; 0.921 for 0.030; 0.821 for 0.100; 0.744 for 0.200; 0.710 for 0.265. F. H. Rathmann

Study of diffusion processes by electrolysis with microelectrodes. H. A. Laitinen and I. M. Kolthoff. *Nature* **144**, 549–50(1939).—The disturbing effects of convection currents on diffusion studies with microelectrodes were detd. Conditions are indicated for the attainment of theoretical diffusion, particularly the shape of the electrode and the direction of the d. gradient. G. M. P.

The behavior of aluminum in cold ammonia solutions. H. Röhrig. *Z. Ver. deut. Ing.* **83**, 1091(1939).—The relation of the action of ammonia solns. of different concns. on Al to the purity of the Al was investigated. 99.5% Al contg. Si 0.15 and Fe 0.23%, and 99.99% Al contg. Si 0.0038, Fe 0.0057, and Cu 0.0007% were ex-

posed at room temp. to aq. solns. of NH_3 of concns. of 0.5, 2, 5, 10, and 21.8% for 1, 2, 4, and 7 days each. The degree of attack was measured by the loss in weight. The results of different series of expts. were tabulated. It was found that in agreement with Calvet (cf. *C. A.* **24**, 578) both Al samples are affected most at medium NH_3 concns. For short periods and for higher NH_3 concns. the pure Al is less attacked than Al 99.5. At medium concns., however, the formation of a surface coating on Al 99.5 samples soon prohibits further effects. This fact renders the use of Al containers for NH_3 solns. practicable. R. Simha

The effect of substituents on the chemical, physicochemical and biological behavior of chemical compounds. A theory of the relation between chemical constitution and biological action. B. Breyer. *Biochem. Z.* **301**, 65–93 (1939).—A theory is developed for predicting the degree of polarity of compds. and of their behavior toward oxidizing or reducing agents, i. e., their reduction-oxidation potentials. This theory is based upon the fact that certain groups affect the d. of the elec. charge on central atoms. Thus, pos. autochromes are groups that increase the polarity of an electropos. central atom, i. e., increase its electrolytic dissocn., in the following order: $—CH_3 < —OCH_3 < —OH < —NH_2 < —NHCH_3 < —N(CH_3)_2 < —NHC_6H_5$, etc. Introduced into compds. with a negatively charged central atom these groups decrease polarity and inhibit dissocn. The presence of pos. autochromes (pos. ionogens) increases the reducing power of compds. and these are oxidized the more easily the more strongly pos. they become. The activity of the NH_2 may be increased by the addn. of alkyls, whereas it is markedly decreased or even abolished by acylation, salt formation, etc. With the OH group its effectiveness is decreased by alkylation, and very much decreased or even abolished by acylation. Neg. autochromes ($—NO$, $—NO_2$, $>CO$, $>SO_2$, $-C{\equiv}N$, $—N{=}N—$, etc.), on the other hand, increase the polarity (ionization) of compds. with an electroneg. central atom, decreasing their reducing power and increasing their ability to become reduced. Finally, amphoteric autochromes (aryl and vinylene groups) increase the heteropolar condition of compds. with either electropos. or electroneg. central atoms. Thus, phenylmercury hydroxide is a strong base, while HgO is an extremely weak base; phenylacetic acid is 3 times as strong as AcOH. The theory, therefore, makes it possible more or less to predict the distribution coeff. of compds. and to alter gradually their soly. in H_2O or lipide until the desired relation is effected. The same applies also to the stability or to the degree of oxidation of these compds. Expts. were made with derivs. of compds. with electropos. ($[C_6H_5Hg]^+$ Cl_3COO^-) and electroneg. ($[C_6H_4NO_3]^-$ H_2) central atoms. With the first it was found that substituents of greater positivity have greater soly. in H_2O, whereas those of greater negativity are less sol. The binding of Hg to C is also a function of the nature of substituted groups, compds. with the strongly pos. groups being unstable whereas those with weakly pos. or neg. groups are stable. Similar behavior was found also in studies on the toxicity of those compds., as predicted by the theory. Studies on benzenearsonic acid derivs. from the point of view of the changes in polarity, degree of reduction, capillary activity and toxicity likewise more or less follow the theoretical prediction. S. Morgulis

Cells without transference for pH determination. Otto Redlich and Hans Klinger. *J. Am. Chem. Soc.* **61**, 2983 (1939).—Cells of the type H_2, H^+X^- + TlBr (satd.), AgBr, Ag are suggested for pH detn. If the soln. forms a ppt. when satd. with TlBr or contains Tl or Br ions in an amt. comparable with the soly. of this salt, an org. Zn salt with Zn-Hg or Ag_2SO_4 with Ag might be used. C. J. West

Potential of lithium amalgam and the activity of lithium ions in isoamyl alcohol. F. I. Trakhtenberg. *J. Phys. Chem.* (U. S. S. R.) **13**, 200–5(1939); cf. *C. A.* **32**, 5683⁹.—Exptl. data are given for the cell $LiHg_x$ | LiCl | AgCl | Ag in isoamyl alc. at 25°, for concns. of LiCl from 0.003 to 0.20 *M*. The cell behaves normally, i. e., LiCl in isoamyl alc. is completely dissocd. The zero potential is 1.800 ± 0.005 v. Some log *f* values are −0.388, −0.440, −0.628, −1.068 and −1.325 for m = 0.00278, 0.00506, 0.0102, 0.534 and 0.1902 resp. The Debye-Hückel law holds with D = 12.9; for $\sqrt{m}$ less than 0.1, the second approximation also holds. The av. ionic radius is 1.72 A. F. H. Rathmann

A thermodynamic study of the zinc–antimony system. The thermodynamic properties of the intermetallic compounds: ZnSb, Zn_3Sb_2 and Zn_4Sb_3. Bernard J. De Witt and Harry Seltz. *J. Am. Chem. Soc.* **61**, 3170–3(1939).—E. m. f. measurements of cells of the type Zn (*l*)|$ZnCl_2$ in LiCl + KCl (*l*)|Zn (in Zn-Sb liquid solns.) made possible the calcn. of the activities and partial molal relative heat contents of Zn and Sb in their liquid melts, the solid soly. of Zn in Sb, the free energies, heats of formation and entropies of ZnSb, Zn_3Sb_2 and Zn_4Sb_3 and the heat of fusion of Zn_3Sb_2. A. B. Garrett

The equilibrium $2COF_2 \rightleftarrows CO_2 + CF_4$. Otto Ruff and Shih-Chang Li. *Z. anorg. allgem. Chem.* **242**, 272–6(1939); cf. *C. A.* **29**, 1346⁶.—The reaction $2COF_2 \rightleftarrows CO_2 + CF_4$ was investigated and its reversibility proved at high temps. The reaction proceeds in the direction of COF_2 with neg. heat of reaction. A. B. Garrett

Apparatus for investigation of oxidation equilibrium of metals by water vapor. Kokiti Sano. *J. Chem. Soc. Japan* **60**, 758–62(1939).—By means of a vertical cylindrical reaction chamber and a spiral manometer the reaction $3Fe + 4H_2O = Fe_3O_4 + 4H_2$ was studied. The results are expressed by $\log K_p = (-1667.4621/T) + 1.492$. The dissocn. pressures of $Sr(OH)_2$ were detd. The results: $\log p_{H_2O}(mm) = (-5405.9738/T) + 8.3846$. T. Katsurai

Reduction by amalgamated zinc. Significant factors in efficiency. Hosmer W. Stone and David N. Hume. *Ind. Eng. Chem., Anal. Ed.* **11**, 598–602(1939).—A detailed study of the effect of nature of oxidant (oxidation–reduction potential, degree of ionization, stability of complexes and tendency to hydrolyze), degree of amalgamation and condition of the amalgam due to age, previous use, method of prepn. and manner of storage on the use of Zn amalgam for reduction in acid soln. With strong oxidants [$Fe_2(SO_4)_3$, $Ce(SO_4)_2$ and $KMnO_4$] reduction was found to be quant. with no deterioration of the amalgam. With oxidants that are not reduced by free Hg [green and violet $CrCl_3$ and $Cr(OAc)_3$, $Cr_2(SO_4)_3$, chrome alum and vanadyl sulfate] there was a pronounced lowering of the rate of reaction after the amalgam had been in use for some time. With these oxidants and with acid concns. of 0.2 *N* or less 0.1% Hg is sufficient. For the stronger oxidants with higher acid concn. as much as 5% Hg is satisfactory. H. A. Frediani

Reactions with atomic oxygen. Peter W. Schenk and Hellmuth Jablonowski. *Z. Elektrochem.* **45**, 650(1939).—An app. similar to that of Geib and Harteck (cf. *C. A.* **26**, 655) was employed in a study of the action of monatomic oxygen upon H_2S, NO_2, Cl_2 and Br_2 at liquid-air temps. With H_2S the reaction proceeded according to the equation, $H_2S + O + O_2 = H_2SO_3$. No free S was formed so long as at. oxygen was present. In the absence of the latter, oxidation to H_2SO_4 was observed. With NO_2 the reaction was $2NO_2 + O = N_2O_5$. Cl_2 and at. oxygen yielded a mixt. of Cl_2O and ClO_2, while Br_2 yielded only BrO_2. No conclusions as to the mechanism of the latter reaction are given. However, it is definitely established that for 1 mol. Br_2 available a max. of $2O_2$ is absorbed. W. A. Cook

The action of strong solutions of potassium ferricyanide. Edward Barnes. *J. Indian Chem. Soc.* **16**, 308–9(1939).—On addn. of 50 cc. of aq. KOH soln. (1:1) to 5 g. of $K_3Fe(CN)_6$ in 10 cc. of water, O_2 of 93.5–95% purity (mixed with a small quantity of N_2) is evolved very slowly at 30°, but briskly at 100°, probably according to the equation, $4K_3Fe(CN)_6 + 4KOH = 4K_4Fe(CN)_6 + 2H_2O + O_2$. The reaction is slower with satd. KOH soln. or with a 1:1.5 soln. of KOH in water, O_2 of 97–8% purity being formed in the latter case. A secondary reaction involving CN groups is indicated by (1) lower yields of O_2 than the

theoretical and (2) the presence of N_2 in the gas liberated. George Ayers

The effect of hydrochloric acid concentration on the reduction of molybdate in the silver reductor. C. F. Hiskey, V. F. Springer and V. W. Meloche. *J. Am. Chem. Soc.* **61**, 3125–7(1939).—The method of Birnbaum and Walden (cf. *C. A.* **32**, 1209[8]) produces quant. reduction of molybdate to the quinquevalent state in the presence of 2 *N* HCl. If the acid concn. is greater than 4 *N*, Mo in the molybdate is reduced mainly to the trivalent state. In high acid concn. as 10 *N*, the reduction shows an apparent valence change as high as 3.1. In a Jones reductor the apparent change of valence for Mo is not greater than 3 even though the acid concn. is as high as 6 *N*. A. B. Garrett

Present problems of chemical kinetics. Luigi Rolla. *Atti XXVII riunione, Bologna, Soc. ital. progresso sci.* **5**, 367–84(1939).—A review of modern developments in soln. kinetics followed by a consideration of the thermodynamic problem of catalysts from a statistical and quantum-mech. point of view. H. A. Frediani

The exchange of hydrogen ions between hydrogen sulfide and methanol. K. H. Geib. *Z. Elektrochem.* **45**, 648–50(1939).—The rates of the H-D exchange reactions between MeOH and D_2S and between MeOD and H_2S were studied at −79°, −97° and −115°, by burning the mixed methanols and detg. the D content of the resulting water by the thermal-cond. method. At −79° the reaction is so rapid that half the equil. concn. is attained in 0.2 to 0.5 min. The heat of activation of the MeOH-D_2S reaction is approx. 7.5–8 kg.-cal., and the process is catalyzed by HCl. The exchange reactions are believed to be prototropic and to involve an ionic mechanism. S. Glasstone

Hydrogen exchange of dimethyl sulfone and sodium-methanesulfonate in alkaline solns. J. Hochberg and K. F. Bonhoeffer. *Z. physik. Chem.* **A184**, 419–28(1939).—Dimethyl sulfone dissolved in alk. D_2O shows a gradual exchange of its H atoms with those of the solvent. For 1 *N* OD-ion concn. the exchange velocity between 0° and 63.5° is given by the expression: $\log k_1(D) = 13.23 - (4035/T)$, where the velocity const. is expressed in reciprocal minutes. The much slower exchange of Na methanesulfonate is given by the following expression for a higher temp. region (100° to 183°): $\log k_1(D) = 12.00 - (5630/T)$. The heat of activation for the D exchange of $CH_3SO_2CH_3$ is 18.5 ± 1 kg.-cal.; for CH_3SO_3Na, 25.7 ± 1 kg.-cal. Victor R. Deitz

Kinetics of reactions of various ion types in solutions. N. V. Sapozhnikova. *J. Phys. Chem.* (U. S. S. R.) **13**, 174–85(1939).—Et and Na monochloroacetates were subjected to various reactions at 15° and 25°. The energies of activation were: $CH_2ClCOOC_2H_5 + Na_2S_2O_3 = EtO_2CCH_2S_2O_3^- + Na^+ + NaCl$, 15.14 Cal.; $ClH_2ClCOONa + Na_2S_2O_3 = NaO_2CCH_2S_2O_3^- + Na^+ + NaCl$, 15.50 Cal.; $CH_2ClCOOC_2H_5 + NaOH = CH_2ClCOONa + C_2H_5OH$, 7.04–7.22 Cal.; $CH_3COOC_2H_5 + NaOH = CH_3COONa + C_2H_5OH$, 11.02–11.62 Cal. For the sapon. of the chloroester by HCl and H_2SO_4, the rate decreases for concns. above 0.5 *N* for both acids; the ratio of the catalytic effect of the 2 acids is practically const. for different concns. For di-Et succinate, the *E* values for the 1st and 2nd stages of sapon. are 14.65 and 9.78 Cal., in agreement with the Moelwyn-Hughes equation. For the reactions $CH_2XCOO^- + NH_3 = CH_2NH_2COO^-$, *E* = 25.85 Cal. for X = Cl, and 22.37 for X = I. F. H. Rathmann

Reaction mechanism of the combustion of carbon from the standpoint of the carbonyl-group theory. V. Sihvonen. *Suomen Kemistilehti* **12B**, 20–3(1939)(in German).—A theoretical discussion, assuming the formation of CO or CCO groups at the solid surface or crystal edges as intermediate products. Gregg M. Evans

The thermal decomposition of biacetyl. F. O. Rice and W. D. Walters. *J. Chem. Phys.* **7**, 1015–18(1939).—The products formed in the decompn. of Ac_2 at 427–470° indicate the reaction $Ac_2 \rightarrow CH_4 + CO + H_2C{:}C{:}O$, followed by some decompn. and polymerization of $H_2C{:}C{:}O$.

1 "The reaction is first order and is only slightly affected by a large increase in the surface-vol. ratio of the reaction vessel. The decompn. has a frequency factor of 10^{17}. A free-radical scheme is proposed for the decompn.: it fails to explain the high-frequency factor. G. M. P.

The homogeneous decomposition of ethyl chlorocarbonate. A. R. Choppin, H. A. Frediani and G. F. Kirby, Jr. *J. Am. Chem. Soc.* **61**, 3176–80(1939).—Et chlorocarbonate decomps. homogeneously and by a unimol. mechanism 2 between 150 and 195° and over a pressure range from 10 to 700 mm. of Hg. A slight effect was noted in the comparison of runs in coated and uncoated vessels. At low pressures the rate const. falls appreciably and the reaction approaches a second-order rate. A. B. Garrett

Kinetics of the thermal decomposition of ethyl formate. R. F. Makens and W. G. Eversole. *J. Am. Chem. Soc.* **61**, 3203–6(1939).—The reaction rates were detd. at 375, 3 400 and 425° for the principal primary reaction which is $HCOOC_2H_5 \rightarrow C_2H_4 + HCOOH$. The energy of activation of this reaction is 40,010 cal. This reaction is followed by the decompn. of formic acid as $HCOOH \rightarrow CO + H_2O$, $HCOOH \rightarrow CO_2 + H_2$ and $2HCOOH \rightarrow CO_2 + HCHO + H_2O$. Several minor primary reactions occur. A. B. Garrett

Kinetics of the sulfonation of nitrobenzene by sulfur trioxide. D. R. Vicary and C. N. Hinshelwood. *J. Chem. Soc.* **1939**, 1372–8.—Solns. of SO_3 in $PhNO_2$ in sealed tubes were opened for analysis after measured peri- 4 ods of time in a thermostat. The reaction goes cleanly to $C_6H_4NO_2SO_3H$, no sulfone being formed. The reaction is of the second order with respect to SO_3, but complicated by a strong retarding effect of the product, owing to formation of an addn. compd. between SO_3 and the sulfonic acid. The activation energy, in the range 25–100°, is 5 11.4 kg.-cal. A. O. Allen

The kinetics of chlorine, iodine chloride and bromine chloride addition to olefinic compounds. E. P. White and P. W. Robertson. *J. Chem. Soc.* **1939**, 1509–15.—Cl reacts with olefins in AcOH and nitrobenzene solns. according to a bimol. mechanism. Br and I, and their chlorides, react according to a trimol. mechanism. When a mol. of olefin, *A*, is struck by the halogen molecule, X_2, a complex, AX_2, is thought to form which reacts with a 6 second mol., *A*. These addn. compds. are theoretically possible when Br and I are involved because these elements are known to be able to expand their outer ring of electrons. Since Cl cannot behave similarly, its reactions must be bimol. From the reaction of olefinic compds. in AcOH with the halogens and halogen halides, it is possible to make the following general comparison of rates: I_2, 1; IBr, 3 × 10^3; ICl, 10^5; Br_2, 10^4; BrCl, 4 × 10^6. The 7 reactions of *cis*- and *trans*-cinnamic acids with Cl are compared. The anomalous behavior of the trans acid is said to be due to its tendency to form the cis acid. This stereoinversion involves the momentary formation of a single link between the ethylene carbons at which moment the mol. is highly reactive. A 1–4 addn. mechanism is proposed for the reaction of $\alpha\beta$ unsatd. aldehydes. F. van S.

The kinetics of bromine addition to olefinic compounds. II. The homogeneous mechanisms. T. K. Walker and P. W. Robertson. *Ibid.* 1515–18; cf. *C. A.* **31**, 4575[2].—The mechanism of the reaction between Br and olefins has been variously reported as bi- and trimol. Actually, the reaction rate is believed to be composite with the trimol. reaction dominant at 25° in the concn. region *M*/40. Diln. favors the bimol. mechanism since the no. of trimol collisions is more affected by concn. changes. For allyl derivs., the bimol. reaction is established at *M*/1000. 9 Increasing the ionization power of the solvent medium also favors the more direct mechanism. One % of H_2O accelerates the reaction between allyl acetate and Br in AcOH at 25° by 95% at *M*/80, and 130% at *M*/1000. A rise in temp. also favors the bimol. reaction which has the higher temp. coeff. This is reflected in a decrease of about 0.2 in the calcd. order of reaction between 17° and 40°. The trimol. mechanism is thought to involve the formation of a complex. F. van Straten

The functional relation between the constants of the Arrhenius equation—the formation of a series of quaternary ammonium salts in benzene-nitrobenzene mixtures. H. C. Raine and C. N. Hinshelwood. *J. Chem. Soc.* 1939, 1378–83; cf. *C. A.* 31, 8291[6]; 32, 7331[8].—Earlier rate studies on quaternary salt formation in C_6H_6–$PhNO_2$ mixts. were extended to evaluate the consts. of the Arrhenius equation for the 4 reactions Me_3N + MeI, Me_3N + iso-PrI, C_5H_5N + MeI and C_5H_5N + iso-PrI over the entire range of solvent compn. In each case, the activation energy E showed max. and min. values when considered as a function of solvent compn., so that there were 2 mixts. in which E has the same value as for pure $PhNO_2$. Differences in the frequency factor, log PZ, in these 3 cases were considered due to a "polarity effect"; when the 3 values of log PZ were plotted against solvent compn., a curve drawn through them gave the polarity effect as a function of solvent compn. Subtracting this curve from the log PZ-solvent compn. curve gave corrected values of log PZ. These corrected values, plotted against E, yield straight lines for each reactant pair; the pos. slopes showed a small regular decrease as the size of the reacting mols. was increased. It was shown that the linear relation is to be expected theoretically if a no. of factors, involving orientation of reactant and solvent mols., must coöperate simultaneously in lowering the value of E. A. O. Allen 1

The Claisen rearrangement. I. A kinetic study of the rearrangement of allyl *p*-tolyl ether in diphenyl ether solution. John F. Kincaid and D. S. Tarbell. *J. Am. Chem. Soc.* 61, 3085–9(1939).—The rate of rearrangement of allyl *p*-tolyl ether in diphenyl ether soln. was measured at 214.7, 200.6 and 185.8°. Over this temp. range and for a five-fold change in concn. the reaction is unimol., and the initial rate of the rearrangement in the pure liquid is the same as in soln. The rearrangement is at least 95% quant. at 200° in soln. The energy of activation is 33.1 kg.-cal./mole. A. B. Garrett 2

Acid- and base-catalysis in light and heavy water. III. Bromination of acetone catalyzed by undissociated acids and by acetate ions. O. Reitz and Johanna Kopp. *Z. physik. Chem.* A184, 429–45(1939); cf. *C. A.* 33, 3240[4].—The bromination of acetone at 25.0° was studied in heavy water with monochloroacetic, glycolic, lactic and acetic acids as catalysts. The bromination was found to be 20 to 30% slower than in light water, with only small differences. Hence in heavy water the catalyzed bromination is twice as fast as in light water. The bromination of heavy acetone (CD_3COCD_3) is slower than that of ordinary acetone by a factor which is practically the same whether the reaction is catalyzed by H ions, by undissocd. acids or by acetate ions; the factor was detd. to be 7.7. The catalyzed bromination of acetone by acetate ions is about 15% slower in heavy water than in light water (solvent effect); the change of bromination velocity as a function of the D content of the acetone is not linear for acetate ion catalysis. Victor R. Deitz 3

The effect of high-tension electrical discharge on catalytic reaction. IV. Reduction of menthone to menthol. Iwao Seto and Mitio Ozaki. *J. Soc. Chem. Ind., Japan* 42, Suppl. binding 271–2(1939); cf. *C. A.* 32, 2816[4].—A material contg. 94.06% of *dl*- and *l*-menthone and 6.12% of menthol (free and combined) was dissolved in paraffin oil (2:3) and, after addn. of 3% of Ni on kieselguhr, 60 cc. of the mixt. was hydrogenated under high elec. tension (25 kv. applied voltage; 0.33–0.74 ma. discharging current) at 135–155°, with yields (without isomerization) of menthol up to 78.49%. The optimum temp. was 145° and the time 180 min. In conjunction with the Ni-kieselguhr catalyst, the paraffin oil and elec. discharge were each shown to contribute to the yield, but the reaction hardly occurred with the elec. action alone. **V. Reduction of thymol to menthol.** *Ibid.* 272–4.—In similar expts. made at 120–160° with a 42.13% soln. of thymol in paraffin oil, yields of menthol up to 66–68% were obtained (reaction time, 2–3 hrs.). Thymol probably is hydrogenated first to menthenol, most of which is transformed into menthone and then reduced to menthol. From vacuum distn. of the product and recrystn. of the acid phthalate esters (prepd. from the distillates) from HOAc and petroleum ether-Et_2O, it was concluded that *dl*-neomenthol, *dl*-menthol, *dl*-isomenthol and *dl*-neoisomenthol were all formed from the thymol. George Ayers 4

Catalysis of hydrazine by Raney nickel. Letterio Irrera. *Atti XXVII riunione, Bologna, Soc. ital. progresso sci.* 5, 353–7(1939).—The vol. of gas obtained by the decompn. of hydrazine hydrate in the presence of Raney Ni is always greater than that indicated by the equation, $2N_2H_4 = 2NH_3 + N_2 + H_2$ postulated for the decompn. in the presence of Pt black. Increasing the amt. of Ni increases the quantity of gas obtained approaching the vol. required by the equation, $3N_2H_4 = 2NH_3 + 2N_2 + 3H_2$. From the data obtained it is suggested that H_2O may play a part in the reaction. H. A. Frediani 5

Catalysts for the synthesis of liquid hydrocarbons from carbon monoxide and hydrogen. VI. Selection of catalysts for the synthesis. (2). Sigeru Tutumi. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) 36, 251–61(1939); cf. *C. A.* 33, 8934[8], 9103[7].—The activity of a Ni catalyst, prepd. by pptn. from nitrate soln. by K_2CO_3, followed by reduction of the oxide by H, diminished more rapidly with increase of temp. of reduction than that of a similar catalyst prepd. by roasting. Apparently K_2CO_3 and KNO_3 were adsorbed on the active spots. A Ni-10% Al_2O_3-100% kieselguhr catalyst prepd. by the pptn. method was fairly active for the CO-H synthesis, but showed a high optimum reduction temp. (450–500°). Reduction of the proportion of Al_2O_3 to 7.5%, or substitution of about 50% of the Ni by Co, lowered the optimum reduction temp. Ni-10% Al_2O_3 and Ni-10% Al_2O_3-100% kieselguhr catalysts prepd. by pptn. were about as active as a Ni-10% Al_2O_3 catalyst prepd. by roasting, for the hydrogenation of C_6H_6, but were more active for the CO-H synthesis. **VII. Activities of the catalysts used for the synthesis.** *Ibid.* 262–70.—The addn. of 0.2–0.3 g. of $NiSO_4$ to a Ni-10%-Al_2O_3-100% kieselguhr catalyst (prepd. by pptn.), contg. 6 g. of Ni, almost completely suppressed its activity for the CO-H reaction, but did not greatly affect its activity for the hydrogenation of C_6H_6, for the suppression of which 0.8–0.9 g. of $NiSO_4$ was required. A catalyst contg. 0.8–0.9 g. of $NiSO_4$ retained its activity for the hydrogenation of nitrobenzene to aniline and of phorone to valerone, and for the water-gas reaction. When the catalysts were prepd. by roasting, less $NiSO_4$ was required to suppress the activity for the hydrogenation of C_6H_6 (0.2–0.3 g. for Ni(6 g.)-10% Al_2O_3 and 0.04–0.05 g. for Ni (6 g.)). It is inferred that the reaction of CO with H is catalyzed by the most active spots, whereas the hydrogenation of C_6H_6 and the other reactions are accelerated by resp. less-active spots. Wm. E. Trout, Jr. 6

Promoting agents in the catalytic actions of ferric hydroxides. Alfredo Quartaroli. *Gazz. chim. ital.* 69, 443–4 (1939).—Attention is called to the fact that the work of Krause, *et al.* (*C. A.* 33, 4116[6]) on the activating effect of Cu on the catalytic action of ferric hydroxides, particularly in its physical aspects, had already been undertaken by Q. (cf. *C. A.* 27, 12) and by Belfiori (*C. A.* 32, 8899[4]). C. C. Davis 7

Phase transitions. Joseph E. Mayer and S. F. Streeter. *J. Chem. Phys.* 7, 1019–25(1939).—*H-T* and *V-P* curves for various types of phase transition are shown. Second-order transitions and an anomalous first-order transition are discussed. A theory of phase transition is presented. It is shown that the Band-Frenkel (*C. A.* 33, 5249[8], 6674[6]) and Ursell developments are not identical. G. M. Petty 8

Magnetic measurements in the system chromium-arsenic. Haakon Haraldsen and Egil Nygaard. *Z. Elektrochem.* 45, 686–8(1939).—In the system Cr–As, as in Cr–S, Cr–Se and Cr–Te, only 3 intermediary phases are present. The range of existence of these phases is between 30 and 50 at. % As. It was not possible to prep. a compd. with the exact compn. CrAs. Surprisingly, the homogeneity range of the single phase is much smaller in the system Cr–As than in the other 3 systems. H. Stoertz 9

Application of physicochemical analysis to the study of

the equilibrium of liquid phases in three-component systems. I. Equilibrium of the liquid phases in the system acetic acid–aniline–benzine (100–125° fraction). F. Zhuravlev. *J. Phys. Chem.* (U. S. S. R.) **12**, 639–46 (1938).—Exptl. data for the system over the temp. range 15–70° are given. The mol. compd. $2C_6H_5NH_2.CH_3COOH$ has its own characteristic dissocn. soly. curve in benzine different from the soly. curve for its components. Above 60° the soly. curve of the ternary diagram is smoothly closed, below 55° it has discontinuities on crossing the benzine-mol. compd. line and free ends on the aniline-benzine side of the triangle. F. H. Rathmann

The ternary system: benzene–toluene–naphthalene. V. M. Kravchenko. *J. Phys. Chem.* (U. S. S. R.) **13**, 133–45(1939).—Exptl. data on the f. ps. of the systems benzene–toluene (I), toluene–naphthalene (II), benzene–naphthalene (III), and benzene–toluene–naphthalene (IV) are given. The eutectic points are, resp., −100.6°, −96.0°, and −3.6° for I (12.35:87.65), II (97.0:3.0), and III (79.8:20.2), and −6° for IV with a benzene–toluene ratio of 9/1; −12° for the ratio 8/2, −18° for 7/3, −24° for 6/4, −33° for 5/5; −43° for 4/6; −58° for 3/7; −80° for 2/8, and −101° for 1/9. A three-component eutetic exists in IV for the compn. 11.0:87.0:2.0 at −102°. F. H. Rathmann

Viscosity in three-component systems formed in Martin furnace slags. The system FeO–CaO–SiO_2. P. P. Kozakevich, S. P. Leiba and E. P. Komar. *J. Phys. Chem.* (U. S. S. R.) **13**, 248–58(1939).—Exptl. data are given for 75 slags of different compns. at temps. from 1200 to 1450°. For 52 of these the viscosity η is a linear function of the temp., for the acid slags with SiO_2 from 43 to 48%, η is of second or third degree with respect to the temp. Evidence of a max. viscosity for the compd. FeO.CaO.SiO_2 reported by Selivanov (cf. *C. A.* **32**, 4116[5], 9005[9]) was very slight. F. H. Rathmann

The equilibrium diagram iron-iron silicide-tungsten. R. Vogel and H. Töpker. *Arch. Eisenhuttenw.* **13**, 183–8 (1939).—Six sections of the ternary system Fe–Fe silicide – W were examd. thermally and microscopically, namely, the satn. areas (1) primary α-Fe solid solns., (2) crystals of the compd. FeSi, (3) crystals of the compd. FeWSi, (4) crystals of the compd. FeW_2Si, (5) primary W solid solns. (98% W) and (6) crystals of the compd. Fe_2W_3. FeSi forms with W a pseudobinary section on which was found the ternary, congruently melting compd. FeWSi, and on which very likely also a ternary, incongruently melting compd. FeW_2Si exists. The compd. Fe_3Si_2 occurring in the system Fe–Si in the solid state forms with a definite ternary solid soln. of the series Fe_3Si_2–Fe_7WSi, in any proportion, solid solns. in the solid state. This definite solid soln. has the compn. 25.75% W, 19.55% Si, 54.7% Fe, corresponding approx. to the formula Fe_7WSi_5. The crystn. conditions are characterized by 3 transition four-phase planes and 1 eutectic four-phase plane. On another fifth four-phase plane, the definite ternary solid-soln. phase is formed, which forms the before-mentioned gapless series of solid solns. with Fe_3Si_2 in the solidus. Two isothermal sections show the fields of state at room temp. and at 1175°. The chem. reactions connected with the various phases are explained in detail and illustrated by photomicrographs of the different alloys in this ternary system. Six references. M. Hartenheim

Effect of an excitation energy on the specific heat of liquid helium II and its relation to the exchange effect in a non-ideal Bose-Einstein gas. A. Michels, A. Bijl and J. de Boer. *Nature* **144**, 594–5(1939); cf. *C. A.* **32**, 8802[7].—At low temps. the sp. heat of an ideal Bose-Einstein gas should increase $T^{1.5}$; in He, the increase is at least $T^{3.5}$. This difficulty can be eliminated by the assumption of an "excitation energy" which must be added to a condensed particle before it can participate in the velocity distribution of the moving particles. This gives a better representation of the anomaly in the sp. heat. G. M. Petty

Specific heat of a substance showing spontaneous electric polarization. J. Mendelssohn and K. Mendelssohn. *Nature* **144**, 595(1939).—The sp. heat of KH_2PO_4 is shown graphically from 40 to 130°K. It lies nearly on a straight line from 7 cal./deg./mole at 40°K. to 18.5 at 130°K., with an anomaly at the upper Curie point (122°K.). No anomaly occurs at the so-called lower Curie point; evidently at 75°K. the mobility of the dipoles freezes in. The data at the Curie point agree well with those of Stephenson and Hooley (*C. A.* **33**, 6131[1]), but not with those of Bantle and Scherrer (*C. A.* **33**, 6130[9]). G. M. P.

Specific heat of methane under pressure. O. N. Trapeznikova and G. A. Milyutin. *Nature* **144**, 632(1939).—The sp. heat of CH_4 was detd. at 1–2000 kg./sq. cm. and at 12–30°K. An anomaly occurs at 20.6°K. and 1 atm.; it follows a straight-line relation to about 30°K. at 2000 kg./sq. cm. A second anomaly was followed from 18.5°K. at 1000 kg./sq. cm. to 27°K. at 2000 kg./sq. cm. The effect on the position of the first max. of substituting D for H is the same as that caused by an increase in pressure: CD_4 at 1 kg./sq. cm. is equiv. to CH_4 at 1410 kg./sq. cm. The displacement of the maxima is directly assocd. with changes in ω. G. M. Petty

Entropy and heat capacity of propylene. B. L. Crawford, Jr., G. B. Kistiakowsky, W. W. Rice, A. J. Wells and E. B. Wilson, Jr. *J. Am. Chem. Soc.* **61**, 2980–1 (1939).—Powell and Giauque (*C. A.* **33**, 9113[1]) published heat-capacity data on solid and liquid C_3H_6 based on a set of frequencies and a potential barrier hindering rotation of the Me group (700 cal.) given by K., Pacher and Stitt (*C. A.* **32**, 6141[6]). Values of the entropy at the b. p. and the gaseous heat capacity over a range of temps. were calcd. with a barrier of 2119 cal. and a no. of frequencies from 432 to 3000 cm.$^{-1}$. The values for the calcd. torsional heat capacity of C_3H_6 gas form a curve on which the observed values fit very well and the entropy is 59.87 cal. as compared with the exptl. value of 59.93. The value of 2120 cal. for the potential barrier is not final. C. J. West

Transference energies. B. Bružs. *Z. Elektrochem.* **45**, 703–6(1939).—Theoretical considerations, based on thermodynamics, of the energy changes accompanying transference processes, with special reference to diffusion and thermal potentials. S. Glasstone

The disperse state of solid matter and its thermodynamic foundations. II. D. Balarev and N. Kolarov. *Kolloid-Z.* **88**, 288–90(1939); cf. *C. A.* **33**, 9087[8].—By detg. the heats of diln. in water of KCl and KBr crystal powders that had been heated at different temps., it was confirmed that the resp. changes of the energy contents of a cryst. system are reversible. These findings support previous conclusions about the thermodynamic foundation of the disperse state of real crystals. Robert Simha

Latent heats of sublimation and evaporation of certain substances. Wm. Hume-Rothery. *Phil. Mag.* **28**, 465–80(1939).—The ratio of the latent heats of sublimation and evapn. for many substances is a no. which is close to a ratio of integers up to 8. Some tentative explanations of this fact are discussed. E. J. Rosenbaum

Heat of formation of magnesium sulfide. A. F. Kapustinskiĭ and I. A. Korshunov. *J. Phys. Chem.* (U. S. S. R.) **13**, 276–7(1939).—For the reaction [Mg] + [S] rhombic = [MgS] cryst., $\Delta H = -84{,}524 + 1.31\,T - 2.88 \times 10^{-3}\,T^2$ and $\Delta F^\circ = -84{,}524 - 3.02\,T \log T + 2.88 \times 10^{-3}\,T^2 + 12.18\,T$. **Heat of formation of manganese sulfide.** *Ibid.* 278–80.—For the reaction [Mn]$_\alpha$ + [S] rhombic = [MnS] green, $\Delta H_{298} = -48{,}750 \pm 520$ cal. Cf. *C. A.* **33**, 6132[6]. F. H. Rathmann

The heat of combustion of isopropanol. Geo. S. Parks and Geo. E. Moore. *J. Chem. Phys.* **7**, 1066–7(1939).—$\Delta H_{298.16} = -478{,}880 \pm 300$ cal./mole at 25° and 1 atm. const. pressure. For the reaction PrOH (liquid) → iso-PrOH (liquid), $\Delta H_{298.16} = -3350 \pm 380$ cal.: $\Delta F^\circ_{298.16} = -3430 \pm 420$ cal. G. M. Petty

Characteristics of optical illustration by means of electrons and applications (electron microscopy). K. Hoffmann. *Kolloid-Z.* **89**, 59-76(1939).—A review with 42 references. G. G.

Quantization under two centers of forces. I. Hydrogen molecular ion. S. K. Chakravarty. *Phil. Mag.* **28**, 423-34(1939).—Math. The energies of the $1s\sigma$, $2s\sigma$ and $3d\sigma$ states of H_2^+ are calcd. as a function of the internuclear distance. E. J. Rosenbaum

Neutral mesotrons and electron pairs. Jacques Solomon. *Compt. rend.* **209**, 678-80(1939); cf. *C. A.* **33**, 6143[7].—Math. results are given showing that Gamow and Teller's theory (*C. A.* **31**, 2919[2]) of nuclear forces is contained in the general theory of the neutral mesotron, and that a mesotron has a magnetic moment of the order of $^1/_4$ Bohr nuclear magneton, and that two possess energy of mutual interaction (cf. Bethe, *Phys. Rev.* **55**, 1261(1939)). C. A. Silberrad

The meson and cosmology. D. S. Kothari. *Nature* **144**, 548(1939).—Math. The mean life of the meson ($\sim 2.5 \times 10^{-6}$ sec.), the cosmological const. ($\sim 2 \times 10^{9}$ years) and the gravitational const. are connected. G. M. Petty

Connection between the life-time of the meson and the β-decay of light elements. C. Møller, L. Rosenfeld and S. Rozental. *Nature* **144**, 629(1939). The discrepancy between the observed and the calcd. ratio of the life of meson to that of a light radioactive element is removed by combining a vector and a pseudoscalar field for the meson in the calcns. G. M. Petty

Scattering of neutrons by protons. C. Kittel and G. Breit. *Phys. Rev.* **56**, 744-9(1939).—Expressions are derived for the calcn. of (*s*) wave scattering for square wells with Wigner's approx. formula (*C. A.* **29**, 401[9]) as a basis. The (*p*) wave phase shifts have been calcd. by use of Bethe's "neutral" form of meson theory (*Phys. Rev.* **55**, 1261(1939)). An effect of about 50% on the angular distribution is expected at 16 m. e. v. where $\mu = 180\ m$ and $^1/_3$ of this amt. for $\mu = 330\ m$ (μ is the mass of the meson; m is the mass of the electron). E. A. G.

Derivation of the dispersion formula for nuclear reactions. A. J. F. Siegert. *Phys. Rev.* **56**, 750-2(1939).—Math. Earl A. Gulbransen

A simple picture of the binding energies of He^3 and He^6. Katharine Way. *Phys. Rev.* **56**, 556-61(1939).—An approx. application of Wheeler's method (*C. A.* **32**, 2825[1]) of resonating groups to the nuclei He^3 and He^6 makes it possible to evaluate the magnitude of the different contributions to the total energy. H. C. Thomas

A method for improved calculation of energies of two-electron configurations from Hartree functions. Application to 2 p^2 terms in O III. A. F. Stevenson. *Phys. Rev.* **56**, 586-93(1939).—A generalization of the method of the self-consistent field previously given by S. (cf. *C. A.* **31**, 6960[7]) is improved by assuming that the radial functions are identical with the Hartree functions, so saving labor, and by taking the core electrons more accurately into account. About $^1/_3$ of the discrepancy in the sepn. $^1S - {}^1D$ in O III is accounted for. H. C. Thomas

Theory of the metallic state. V. V. Tarasov and B. P. Bering. *J. Phys. Chem.* (U. S. S. R.) **13**, 124-32(1939).—Data are given on the electron nos. and the electron vols. of most of the metals. The values of $B_0 \times 10^{13}$ in the Fermi equation calcd. from exptl. data vary from 0.85 for Sn to 1.25 for Ir; most of the values lie close to the av., 1.00_8 (theoretical value 1.00_8). The relation between the concn. of electron gas and the m. p. is discussed. F. H. Rathmann

Apparatus for the production of acceleration fields for atomic-physical investigations. The cyclotron. R. Elsner and R. Strigel. *Z. Ver. deut. Ing.* **83**, 1083-8(1939); cf. *C. A.* **33**, 9128[6].—A review. Robert Simha

Current densities, lumen efficiency and brightness in argon, nitrogen, helium and hydrogen arcs. C. G. Suits. *J. Applied Phys.* **10**, 730-2(1939); cf. *C. A.* **33**, 5281[1]. A. O. Allen

Influence of the cathode on the sparking potential of hydrogen. F. Llewellyn Jones and J. P. Henderson. *Phil. Mag.* **28**, 185-91(1939); cf. *C. A.* **33**, 5754[4].—Sparking p. ds. were measured at H pressures in the range 1–520 mm. for disk cathodes of clean and oxidized steel, pure and com. Al, Ni and Cu. The sparking p. d. depends on the cathode material but since the change due to a change of cathode material is independent of the pressure, the relative change at a pressure above 1 atm. is small. The min. p.-d. values are 266.5, 280, 295 and 312.5 v. for Al, Ni, Cu and Fe, resp. E. J. Rosenbaum

Mechanism of the spark discharge in hydrogen. F. Llewellyn Jones. *Phil. Mag.* **28**, 192-202(1939); cf. preceding abstr.—The dependence of the sparking p. d. of H on the cathode material is interpreted in terms of the Townsend theory of the discharge. Over a large pressure range the secondary ionization is due mainly to pos. ions; the effect of radiation from the gas is predominant only at the highest pressures. The min. fraction of the total secondary ionization which must be due to emission of electrons is calcd. E. J. Rosenbaum

Influence of the cathode on the sparking potential of heavy hydrogen. F. Llewellyn Jones. *Phil. Mag* **28**, 328-37(1939); cf. preceding abstr.—As with H, the min. sparking p. d. is characteristic of the cathode material and is lowered by slight oxidation of the cathode surface. The min. p. d. with D is about 3% greater than with H. The values obtained after the discharge tubes remained evacuated are higher than those after exposure to the gas. The variation of the sec. Townsend coeff. was studied as a function of the ratio of the field strength to the gas pressure. E. J. Rosenbaum

A differential method applied to the surface ionization of sodium halides on tungsten. A. A. Johnson and T. E. Phipps. *J. Chem. Phys.* **7**, 1039-46(1939).—A differential mol.-beam method for the study of the surface ionization of salts was developed. The method was applied to the study of the ionization of Na halides on W and W-O surfaces. The results disagreed with the simple theory of the ionization of a gaseous Na atom at a W surface: apparently 2–4% of the W surface (varying with the surface and with the halide) held adsorbed halogen atoms up to 2600°K. G. M. Petty

Electron interference in convergent rays. W. Kossel and G. Mollenstedt. *Ann. Physik* **36**, 113-40(1939); cf. *C. A.* **33**, 2027[8].—In order to observe the elementary diffraction phenomena finite openings were introduced in place of the customary parallel beams of electrons. In addn. to the regular reflections and multiple reflections in very thin single crystals a new system of parallel interference lines appears, which are related to the boundaries of the crystal and its finite thickness. These serve as a means for observing the propagation of electron waves in the crystal. S. L. Gerhard

The mechanism of secondary electron emission. R. Suhrmann and W. Kundt. *Naturwissenschaften* **27**, 707(1939).—Metal films of which the secondary electron yield and its change with temp. were recently detd. (*C. A.* **33**, 9132[6]) were studied for penetration power of secondary electrons. A cooled (83° abs.) sensitized Be layer of high yield (S/P between 4 and 5) was covered with a thin film, transparent for slow electrons, of Be, Cu or Ag. Their S/P was detd. at 83° abs. before and after heating to room temp. to cause orientation of the film. It followed that the penetration power is smaller in the irregular condition than in the oriented condition. The no. of emitting centers is larger in the irregular state. It is assumed that the emit-

ting centers are disturbed spots in the compact metal layer, more of which are present in the irregular arrangement than after orientation. Possibly these spots have free atoms in which the electrons are not bound (cf. Mahl, *Jb. AEG Forsch.* **6**, 33 (1939)). B. J. C. van der Hoeven

Secondary electron emission. IV. Compounds with a high capacity for secondary electron emission. H. Bruining and J. H. de Boer. *Physica* **6**, 823–33 (1939) (in English); cf. *C. A.* **33**, 2028⁸.—Any pure alkali metal compd. easily emits secondary electrons, these coming principally from the highest energy level of the nonmetallic element. The metal furnishes cond. electrons. **V. Mechanism of secondary electron emission.** *Ibid.* 834–9.—An energy diagram is used to explain the conclusions in the above article. Gregg M. Evans

Production of a beam of fast neutrons. Paul C. Aebersold. *Phys. Rev.* **56**, 714–27 (1939).—The app. consists of a tapering channel of paraffin lined with Pb on both the inside and outside of the channel, in conjunction with the 8-m. e. v. D-Be source of a cyclotron. Ionization measurements and photographs indicate that the fast neutron effects are localized in the collimated beam. The beam was found suitable for many phys. and biol. expts. Earl A. Gulbransen

Nuclear reactions in stellar evolution. G. Gamow. *Nature* **144**, 575–7, 620–2 (1939); cf. *C. A.* **32**, 4065⁸, 8254⁷.—Values for Q (energy of reaction) and Γ (Γ/h = probability of reaction after penetration of the potential barrier) are tabulated for nuclear reactions of H^1 with H^1, H^2, H^3, Li^6, Li^7, Be^9, B^{10}, B^{11}, C^{11}, C^{12}, C^{13}, N^{14}, N^{15}, O^{16}, F^{19}, Ne^{22}, Mg^{26} or Si^{30}. It is shown that energy production in the sun is due to the cycle: $C^{12} + H^1 \rightarrow N^{13} + h\nu$; $N^{13} \rightarrow C^{13} + e^+$; $C^{13} + H^1 \rightarrow N^{14} + h\nu$; $N^{14} + H^1 \rightarrow O^{15} + h\nu$; $O^{15} \rightarrow N^{15} + e^+$; $N^{15} + H^1 \rightarrow C^{12} + He^4$ (C^{12} and N^{14} are catalysts for the reaction $4H^1 \rightarrow He^4 + 3h\nu + 2e^+$). The positions on the Hertzsprung-Russell diagram of those stars which derive their energy from the C-N cycle and the direction of motion of the sun on that diagram during its evolution are discussed. The positions on the diagram occupied by red giant stars and variable stars and the positions of stars whose sources of energy are principally B^{10}, B^{11}, Be^9, Li^7, Li^6, H^3 and H^2 reactions are indicated. The course of stellar evolution is briefly discussed. The problem of stellar energy sources and the main features of stellar evolution can be considered as practically solved. G. M. Petty

Helium and hydrogen of mass 3. Luis W. Alvarez and Robert Cornog. *Phys. Rev.* **56**, 613 (1939); cf. *C. A.* **33**, 8106⁵.—The isotopic ratios He^3/He^4 are 10^{-5} for gas-well He and 10^{-7} for atm. He. He^{+++} ions, at 24 m. e. v., induce a radioactivity in Si: $_{14}Si^{28} + {}_2He^3 \rightarrow {}_{15}P^{30} + {}_1H^1$; ${}_{15}P^{30} \rightarrow {}_{14}Si^{30} + e^+$. H^3 has a definite activity of long half-life. G. M. Petty

The energies released in the reactions $Li^7(p,\alpha)He^4$ and $Li^6(d,\alpha)He^4$, and the masses of light atoms. Nicholas M. Smith, Jr. *Phys. Rev.* **56**, 548–55 (1939).—The energies of α-particles arising from the reactions $Li^7(p,\alpha)He^4$ and $Li^6(d,\alpha)He^4$ were measured by stopping the particles in a calibrated, variable-pressure, air-filled absorption cell. The energy release of the Li^7 disintegration was found to be 17.28 ± 0.03 m. e. v.; that for Li^6, 22.20 ± 0.04 m. e. v. Taken together with the Be-proton disintegrations the following masses for the light atoms are obtained: Li^6, 6.01682 ± 0.00011; Li^7, 7.01784 ± 0.00009; Be^8, 8.00766 ± 0.90015; Be^9, 9.01486 ± 0.00013. H. C. Thomas

Noninterchange of elementary radiosulfur with carbon disulfide. Robert A. Cooley, Don M. Yost and Edwin McMillan. *J. Am. Chem. Soc.* **61**, 2970–1 (1939).—Results are reported to show that there is practically no interchange between S and CS_2 even at 100°. The extent of any interchange must be less than 2% or less than the exptl. error of the activity measurements. Therefore, CS_2 may be used as a solvent for radio-S without fear of loss by interchange. C. J. West

β-Ray spectra of Mg^{27}, Cu^{62} and the nuclear isomers of Rh^{104}. E. C. Crittenden, Jr. *Phys. Rev.* **56**, 809–13 (1939).—The cloud chamber is used to investigate the β-ray spectra of several radioactive elements. The following results were obtained: (1) the spectrum of Mg^{27} gave an upper limit of 1.8 m. e. v., (2) the spectrum of Cu^{62} gave an upper limit of 2.6 m. e. v., (3) the spectra of the 2 nuclear isomers of Rh^{104} were found to have the same upper limit of 2.3 m. e. v. and the same shape within the exptl. error. The similarity in shape of the 2 spectra leads C. to explain the disintegration of the 4.37-minute isomer as proceeding entirely by a γ-ray transition to the ground state of Rh^{104} followed by a β-ray transition to the ground state of Pd^{104}. Earl A. Gulbransen

Deuteron bombardment of silver. R. S. Krishnan and D. H. T. Gant. *Nature* **144**, 547 (1939).—Pure Ag was bombarded with 9-m. e. v. deuterons. The activities are listed in the order of their prominence. (1) An activity (e^-) of 2.4 min.: $Ag^{107}(d,p)Ag^{108}$. (2) The active ppt. was chemically sepd. into Cd and Ag fractions. The Cd fraction contained a 6.8-hr. substance emitting a soft e^- radiation, x-rays and a very weak γ-radiation. The reaction is $Ag^{107}(d,n)*Cd^{108}$ or $Ag^{109}(d,n)*Cd^{110}$. (3) The Ag fraction contained a 26-min. substance emitting e^+, with an absorption unit of 1.8 m. e. v. This suggests Ag^{106}, but the 8-day period was missing. (4) The Ag fraction exhibited an e^- activity with a life of at least several weeks. (5) No activity shorter than 2.4 min. could be detected. G. M. Petty

Deuteron bombardment of silver. N. Feather. *Nature* **144**, 547 (1939); cf. preceding abstr.—By use of the method of crit. absorption (*C. A.* **33**, 4870¹), the data and interpretations of Krishnan and Gant were confirmed. G. M. Petty

A particular mode of fission of the uranium nucleus. V. G. Khlopin, M. A. Pasvik-Khlopina and N. F. Volkov. *Nature* **144**, 595–6 (1939).—Na pyrouranate was exposed to slow neutrons from Rd-Th + Be for 17 days; the fission products were sepd. chemically. The ppts. and their half-lives were: La + K, 30 min., 9.5 hrs., 45 hrs.; Sr, 20 min., 7.5 hrs. and one isotope of much longer period, Ba, 10 and 50 hrs. A sample of U oxide was irradiated 36 hrs. with slow neutrons in a cyclotron. Some transformation products were gathered from the vessel walls. Radio-isotopes of Kr and Xe are intermediary products of the fission, coming in the middle of the transmutation chain. G. M. Petty

Fission of thorium by neutrons. Y. Nisina, T. Yasaki, H. Ezoe, K. Kimura and M. Ikawa. *Nature* **144**, 547–8 (1939); cf. *C. A.* **33**, 1211⁵.—Th nitrate, carefully freed from MsTh and other disintegration products except RdTh, was exposed 1–5 hrs. in the cyclotron to fast neutrons from D + Li. Chem. sepn. showed the presence of radioactive Bi, Hg, Sb, Sn and Ag: radioactive elements in the alkali, halogen, Mo, Se + Au and Cu + Cd fractions have not been identified. Radioactive Pb and As were absent. The chem. sepn. required 2–3 hrs., so short-lived radioelements escaped detection. Starting with U, radioactive ppts. of Bi, Hg, Ag, Sb + Sn and the Cu + Cd fraction were obtained. G. M. Petty

The radioactivity of potassium as a means for determination of the relative age of elements in meteorites. Hans Suess. *Naturwissenschaften* **27**, 702 (1939).—The radioactivity of K from tectites (*C. A.* **32**, 8920⁹) and from meteorites (1868, 1882 and 1932) was detd.; the K content of the latter was from 0.1 to 0.3%. Geiger-Müller tube measurements on KCl, corrected for cosmic radiation, showed a ratio between activity of terrestrial K and cosmic K of from 0.91 to 1.2. On the average all values are within the limits of error of 5 to 10%. This result of identity of both K species seems to indicate that the elements of the earth were formed at the same time as those of a wide expanse of the universe (catastrophe theory). Difference in age would have been indicated by difference in K^{40} content and in radioactivity. B. J. C. van der Hoeven

Element 87 (moldavium, Ml). Horia Hulubei. *Compt. rend.* **209**, 675–8 (1939); cf. *C. A.* **32**, 421⁹.—Processes deemed likely to conc. this element, in particular that based on differences in the soly. of the alkali chlorides obtained, applied to various minerals, etc., e. g., pollucite, beryl, lepidolite, autunite and various com. samples of

Rb and Cs salts, showed in some cases an undoubted strengthening of the line $L\alpha_1$ attributable to Ml. Results with autunite were the most hopeful. C. A. Silberrad

A precision camera for measuring lattice constants by the powder method. Giulio Cesoni. *Atti XXVII riunione, Bologna, Soc. ital. progresso sci.* **5**, 323–30(1939).—A simplification of the Straumanis and Jevins camera (*C. A.* **30**, 2447[4]) for obtaining Debye-Scherrer photographs is described. Its advantages include rigid connection between the film and sample supports and a camera diam. of 86 mm. for facilitating calcns. A study of Al indicated a precision of from 0.0002 to 0.0008 A., identical with that of S. and J. H. A. Frediani

L spectrum of tungsten: strong lines. Mme. Marcel Rouault (nee Boudin). *Compt. rend.* **209**, 650–1(1939).—Remeasurements of 24 *L* lines of W were made with Cauchois' spectrograph, each line being measured by comparison with the nearest $K\alpha$ lines of other elements on each side. Results generally agree well with those previously obtained, the av. difference being 0.17 X. U. (0.01–0.44) (cf. Friman, *C. A.* **21**, 794, and Idei, *C. A.* **25**, 2638). C. A. Silberrad

Identification of characteristic x-rays associated with radioactive decay. Philip H. Abelson. *Phys. Rev.* **56**, 753–7(1939).—A bent rocksalt crystal spectrograph is applied to the identification of x-rays emitted during radioactive decay. The x-rays assocd. with the disintegration of $_{31}Ga^{67}$, $_{29}Cu^{64}$, $_{35}Br^{80}$ and $_{43}Ma$ have been identified. Earl A. Gulbransen

Magnetic moments of the proton and the deuteron—radiofrequency spectrum of H_2 in various magnetic fields. J. M. B. Kellogg, I. I. Rabi, N. F. Ramsey, Jr., and J. R. Zacharias. *Phys. Rev.* **56**, 728–43(1939); cf. *C. A.* **32**, 5291[8]; **33**, 2802[2].—The mol.-beam magnetic-resonance method is used to measure the magnetic moments of the proton and deuteron. The radiofrequency spectrum of ortho-hydrogen in the first rotational state was obtained and 6 resonance minima were found. The analyzed spectrum yields 9 energy levels, from which are obtained (1) the proton moment from the Larmor precession frequency—$\mu_P = 2.785 \pm 0.02$ nuclear magnetons, (2) the proton moment from the magnitude of the dipole interaction between the 2 magnetic moments $\mu_P/r^3 = 34.1 \pm 0.3$ gausses which gives $\mu_P = 2.785 \pm 0.03$ nuclear magnetons and (3) the value of the spin orbit interaction const. of the proton moment with the rotation of the mol. or the magnetic field H' produced by the rotation of the mol. at the position of the nucleus. $H' = 27.2 \pm 0.3$ gausses. The deuteron magnetic moment was found to be $\mu_D = 0.855 \pm 0.006$ nuclear magnetons. Earl A. Gulbransen

Influence of temperature on the pressure broadening of spectral lines. H. Horodniczy and F. Jabłoński. *Nature* **144**, 594(1939); cf. *C. A.* **33**, 2032[9].—The influence of temp. (420–1300°K.) on the width of the Hg absorption line 2537 A. was found to be 3.6% (the av. of plates which varied from −2.3% to +10%). The const. concn. of Hg was 6×10^{14} atoms per cc., with 1.4×10^{19} atoms of A. per cc. This broadening is substantially smaller than that calcd. from the theories of Lorentz (*Proc. Roy. Acad. Amsterdam* **8**, 591(1906)) or of Weisskopf (*C. A.* **27**, 1830). There was a slight diminution of the asymmetry of the line with increasing temp. G. M. Petty

The forbidden $^3P_0$-$^1D_2$ line of O III in the nebular spectrum of Nova Herculis 1934. J. Dufay and M. Bloch. *Nature* **144**, 593–4(1939); cf. *C. A.* **32**, 7818[3].—The forbidden $^3P_0$-$^1D_2$ line of O III, the transition probability of which is small but not zero, was identified in the spectra of 2 nebulae (Bowen and Wyse, *Public. Astro. Soc. Pacific* **51**, 348(1938)). The line 4932.2 ± 0.6 A., which was observed in the nebular spectrum of Nova Herculis, is attributed to this transition. G. M. Petty

Line absorption spectra of rare earth ions in crystals. E. J. Meehan and G. C. Nutting. *J. Chem. Phys.* **7**, 1002–11(1939).—Absorption spectra of the sulfate octahydrates or Er^{+++} (161 lines) and Ho^{+++} (98 lines) at 14, 20, 78, 169 and 300°K., of Dy^{+++} (99 lines) at 20, 78 and 300°K. and of Tm^{+++} (35 lines) at 20 and 78°K. are tabulated. Energy levels were found in Er^{+++} at 19, 41 and 86 cm.$^{-1}$ above the normal state, and in Dy^{+++} at 22 and 57 cm.$^{-1}$ above the lowest; no such low energy states were found in Ho^{+++} or in Tm^{+++}. G. M. P.

Bands of the first positive system of the nitrogen molecule. René Bernard and Renée Fouillouze. *Compt. rend.* **209**, 647–50(1939); cf. *Thèse*, Paris, (1939).—Intensity-exciting energy (I/E) curves for 3 bands (heads λλ 8546, 6323 and 6071) of the first pos. system of $N_2(1P)$ were detd. by the method used for the bands N_2^+ and $N_2(2P)$, with thoriated-W cathodes. The curves, which are similar for all 3 bands, rise slowly from $E = 7.5$ v. to $E = 10.5$, and then very rapidly to 13.5, at which there is a sharp max.; they then decrease more slowly. Variations in pressure from 0.7 to 0.01 mm. Hg or addn. of He or Ne has no effect. C. A. Silberrad

Apparent anomalous isotopic effect in some bands associated with the Swan bands. Chas. H. Townes. *Nature* **144**, 631(1939).—Heads of bands due to C^{12} were identified at 4770.21, 4836.16 and 4910.95 A.; of C^{13}, at 4764.77, 4827.57 and 4898.92 A. The emitting mol. contains only 1 C atom. The anomalously large isotopic shift indicates the presence of C combined with a persistent impurity; the mol. should not be very complex. G. M. Petty

Absorption spectrum of vapors in presence of a foreign gas (spectrum of ICl). Michel Kantzer. *Compt. rend.* **209**, 675(1939).—The spectrum of ICl in presence of various amts. of H_2, N_2, O_2 or CO_2 was examd. If the pressure of ICl is above 0.1 mm. Hg absorption increased with the proportion of added gas to a limit; if below, it passed through a max. before reaching the limit; both max and min. depend on the nature of the added gas. C. A. S.

The near ultraviolet absorption of substituted benzenes. A. L. Sklar. *J. Chem. Phys.* **7**, 984–93(1939); cf. *C. A.* **31**, 7758[8].—Math.-theoretical. The intensification of ultraviolet absorption in substituted over unsubstituted C_6H_6 is attributed to the destruction of the 6-fold symmetry of C_6H_6 by the partial migration of an electron to the ring or out of it. Calcns. made for PhMe, $PhNH_2$, PhOH and PhF agree with empirical data. The SH group should be particularly effective in intensifying the absorption. G. M. Petty

Absorption spectra of solid substances. Masahisa Kobayasi and Ryutaro Tutida. *J. Chem. Soc. Japan* **60**, 769–73(1939).—The technique of the detn. of light absorption by the single-crystal method, the microscopic method and the reflection method has been worked out. The absorption spectra of Cr alum, $[Co(NH_3)_4Cl^{(1)}_{(2)}]$, $[Co(NH_3)_4CO_3]Cl$, $[Co(NH_3)_4CO_3]NO_3\frac{1}{2}H_2O$, $[Co(NH_3)_4CO_3]_2SO_4.3H_2O$, ZnS, CdS and of Hg are given. T. K.

The infrared absorption by hydrogen selenide, deuterium selenide and deuterium hydrogen selenide. Donald M. Cameron, Wm. C. Sears and Harald H. Nielsen. *J. Chem. Phys.* **7**, 994–1002(1939).—Infrared spectra are reported in graphs and in tables for H_2Se (4.05–4.58 and 8.0–10.3 μ), D_2Se (5.5–6.5 and 11.5–14.2 μ) and HDSe (4.0–4.5, 5.5–6.3 and 10.0–11.6 μ). The fundamental frequencies $\nu_{1,2,3}$ are, in cm.$^{-1}$: H_2Se, 2260, 1074, 2350; D_2Se, 1630, 744, 1696; HDSe, 1691, 905, 2352. The angle H-Se-H is slightly more than 90°. The distances H-Se and H-H are 1.6 and 2.3 A., resp. The product relations of Redlich (*C. A.* **29**, 4673[2]) are used to verify assignments of frequencies and detns. of band centers. G. M. Petty

The spectroscopic determination of the carbon-chlorine distance in methyl chloride. G. B. B. M. Sutherland. *J. Chem. Phys.* **7**, 1066(1939); cf. *C. A.* **32**, 2796[7].—The discrepancy between the diffraction (1.77 ± 0.02 A.) and spectroscopic (1.66 ± 0.05 A.) values for the C-Cl distance in MeCl is increased by the interpretation of the spectrum by Nielsen and Nielsen (*C. A.* **33**, 9138[2]). The newer results are reinterpreted, and the discrepancy is slightly reduced. G. M. Petty

Spectroscopic apparatus. Wm. F. Meggers. *J. Applied Phys.* **10**, 734–40(1939).—A review with 31 references. E. H.

Wide-range intensity-measurements in photoelectric

spectrophotometry. Walter C. Bosch and Barremore B. Brown. *J. Optical Soc. Am.* **29**, 466–9(1939). E. H.

The oscillation frequencies of nitrites. Dudley Williams. *J. Am. Chem. Soc.* **61**, 2987–90(1939).—The infrared absorption spectra of $NaNO_2$, and KNO_2 were studied between 5 and 16 μ. Absorption bands were observed at 7.6, 8.2 and 13.3 μ, which are interpreted as arising from fundamental vibrations of the nitrite group. The valence-force-field proves to be an unsatisfactory approximation for the nitrites. The HNO_2 spectrum is compared with the nitrite spectra. It is suggested that the similarities in these spectra may be accounted for on the basis of OH and NO_2 groups in HNO_2. A. B. Garrett

Rotatory dispersion and absorption spectra of carboxylic acids and hydrocarbons containing a phenyl or a cyclohexyl group. Alexandre Rothen and P. A. Levene. *J. Chem. Phys.* **7**, 975–83(1939).—Max. optical rotations are tabulated for (*a*) MeCHRCOOH, (*b*) MeCHRCH$_2$COOH, (*c*) EtCHRCOOH, (*d*) PrCHPhCH$_2$COOH, (*e*) EtCHPhBu, (*f*) RCH$_2$CHMeCOOH, (*g*) RCH$_2$CHMeCH$_2$COOH, (*h*) PhCH$_2$CHMeEt, (*i*) RCH$_2$CH$_2$CHMeCOOH, (*j*) RCH$_2$CH$_2$CHMeCH$_2$COOH, (*k*) PhCH$_2$CH$_2$CHMeCH$_2$CH$_2$COOH, (*l*) cyclo-C$_6$H$_{11}$CH$_2$CH$_2$CHMeCH$_2$CH$_2$COOH, (*m*) RCH$_2$CH$_2$CHMeCH$_2$CH$_2$CH$_2$COOH, (*n*) PhCH$_2$CH$_2$CHMeEt, where R = Ph, cyclo-C$_6$H$_{11}$ or C$_6$H$_{13}$. Calcd. and observed rotatory dispersions are compared at 3–23 wave lengths between 2300 and 6700 A. for solns. in heptane of all the Ph compds. except *a*, and the cyclohexyl compds. *a*, *b*, *c*, *f* and *g*; and for the cyclohexyl compds. *i*, *j*, *l* and *m* and for *e*, *h* and *n*: rotatory dispersions are plotted ($1/\alpha$ against λ^2) for the Ph compds. *b*, *f* and *m*, and for cyclohexyl compds. *a*, *f* and *i*; the max. mol. rotations are plotted against $\lambda\lambda$ (3900–6300) for cyclo-C$_6$H$_{11}$CHEtCOOH. Absorption spectra are plotted $\lambda\lambda$ (2200–2800) for the Ph compds. *b*, *c*, *f*, *i*, *j*, *m* and *n*; for the cyclohexyl compds. *a*, *l* and *m*; and for PhCHMeBu. Absorption bands (5–7 each) of PhCH$_2$CONH$_2$, Ph(CH$_2$)$_6$CONH$_2$, PhMeCHCOOH, PhCH$_2$CH$_2$CHMeCOOH and PhCH$_2$CH$_2$CHMeCH$_2$COOH are compared. Shifts in the absorption bands of these disubstituted carboxylic acids were studied as a function of the Ph—COOH distance. The first absorption region of the Ph group furnishes no detectable rotatory contribution in this type of acid. The first rotatory contribution is allocated to the COOH group. The Ph and cyclohexyl groups have a vicinal effect similar to that of the hexyl group with respect to the sign of rotation. G. M. Petty

Polarization and resonance in the study of aromatic nuclei. I. Benzene and substituted benzenes. G. B. Bonino. *Gazz. chim. ital.* **69**, 417–35(1939).—In the present paper, certain concepts concerning the constitution of aromatic nuclei, which have already been described (cf. *C. A.* **30**, 2849[4]), are applied to the polarization phenomena of the electronic cloud induced by substituents, and to the resonance phenomena between the electronic wave of the aromatic nucleus and the substituents with analogous symmetry. When the concomitant effect of polarization and of resonance induced by substituents in the aromatic ring results in a "displacement" of the d. of the cloud of the p_z charge of the C_6H_6 nucleus toward the substituent itself, it is of advantage in studying the phenomenon (very complex in itself and difficult to express qualitatively) to regard the electronic group remaining in the aromatic system (p_z) as sep. from the electronic group assocd. with the substituent. In the particular case treated, viz., BzOH, this relatively simple hypothesis is shown to be of aid in evaluating the phenomena in a qual. way. It is also applicable to the study of $C_{10}H_8$ and condensed aromatic nuclei in general. C. C. Davis

Studies in photoelectric photometry. A photoemissive cell specially designed for high-precision measurements. G. A. Boutry and P. Gillod. *Phil. Mag.* **28**, 163–84(1939).—Reasons were studied for deviations from proportionality between the illumination on a photocell and the resulting current. These reasons are the ionization of the residual gas, space charge and the influence of surface charges on the walls of the cell. Two types of cell are described for which the response is strictly linear. One has a disk cathode surrounded by a guard ring, and a parallel anode which is a grid of fine wires. The other consists of a cathode at the end of a Faraday cylinder. This cell has a satn. p. d. of about 0.1 v. and a very small space charge. Both of these cells are used with such a low p. d. that dark current is negligible. E. J. Rosenbaum

Optical activity and magneto-optical activity of crystalline nickel sulfate in the near ultraviolet. F. G. Slack and Philip Rudnick. *Phil. Mag.* **28**, 241–7(1939); cf. *C. A.* **32**, 8938[8].—The rotatory power of the α hexahydrate of $NiSO_4$ in the wave-length range 3400–6300 A. is represented by $\alpha = [0.718/(\lambda^2 - 0.0244)] + [1.834/(\lambda^2 - 0.8156)] + [0.0104/(\lambda^2 - 0.1482)]$. The value of n is given by $n^2 - 1 = 1.2461 + 0.012126/[\lambda^2 - (0.135)^2]$ and the magnetic rotatory dispersion by $n\,\delta = 0.01025\lambda^2/[\lambda^2 - (0.135)^2]^2$. E. J. Rosenbaum

Measurement of light components in mixed phosphors with mixed luminous materials. Peter Brauer. *Ann. Physik* **36**, 97–104(1939).—The contribution of each component to the total light emitted was estd. by measuring the intensity of individual lines in the emission spectrum of the mixt. In CaO-PrSm phosphors the emission from Sm was strongly suppressed by Pr, for several values of the Sm/Pr ratio. Momentary excitation showed that the Sm was nevertheless capable of emitting light. The suppressive effect depends upon the total concn. Applications to other problems in phosphorescence are discussed. S. L. Gerhard

An arrangement of apparatus for the isolation of monochromatic light of high intensity at λ, 254 mμ. Lawrence J. Heidt. *Science* **90**, 473–4(1939). E. H.

Experimental studies of the phenomena accompanying the emission of light. O. Deutschbein. *Ann. Physik* **36**, 183–8(1939).—A study was made of the directional relations of intensity and polarization of the light emitted by Eu ions in crystals of Eu salts, viz., the hexagonal bromate and Et sulfate, the monoclinic sulfate and the triclinic acetate, when excited by ultraviolet light. It was found that some groups of emission and absorption lines can be ascribed to radiation from magnetic dipoles, for which $\Delta J = \pm 1$, and others to emission from elec. dipoles, for which $\Delta J = \pm 2$. S. L. Gerhard

Investigation of the CO-O_2 flame. V. Influence of temperature on the yield of visible light in the spectrum of the 2CO + O_2 flame. E. Kondrat'eva and V. Kondrat'ev. *J. Phys. Chem.* (U. S. S. R.) **13**, 169–73(1939); cf. *C. A.* **33**, 4523[9], 8091[4].—For combustions of less than 10% the yield of light is independent of the flame temp. (620–730°). For greater values of γ, the yield of light decreases with increasing temp. Since the quenching effect of CO_2 was shown to be less than that of CO and O_2 mixts., K. and K. conclude that the decreased yield is due to interaction of the reaction chains at higher temps. F. H. Rathmann

Mechanism of photochemical formation of hydrogen peroxide. K. Yamahuzi, N. Nisioeda and H. Imagawa. *Biochem. Z.* **301**, 404–17(1939).—According to the authors the photochem. formation of H_2O_2 is of 3 types: (I) $2H_2O = H_2O_2 + 2H$; (II) $2H + O_2 = H_2O_2$; (III) $AH_2 + O_2 = H_2O_2 + A$, where A is an oxidizable substance. According to Baur and Neuweiler (*C. A.* **22**, 1104) the presence of O_2 is essential for the photochem. production of H_2O_2 from H_2O, but the authors maintain that this reaction proceeds in the absence of O_2 when biol. photosensitizers are present. In a series of expts. using ZnO, eosin or hematoporphyrin as sensitizers, there was a large increase in H_2O_2 in the presence of glucose, glycerol or glycine only with ZnO. Similarly a large increase in the H_2O_2 formation was found when eosin or hematoporphyrin was illumined in the presence of photosensitizing prepns. from yeast or leaves. With ZnO there was no increase or only a small increase under similar exptl. conditions. Expts. were made in manometers to det. if any O_2 is taken up when ZnO, eosin, hematoporphyrin or the biol. prepns. are illumined, but uniformly the gas vol. (O_2) remained unchanged. The H_2O_2,

which appears in measurable amts. after 5 sec., is shown to be formed even when ordinary room light is used but fails to appear in the dark. The H_2O_2 formation with ZnO, which is not affected by the amt. of sensitizer, is greatly increased by the addn. of glucose, and for a given amt. of ZnO increases progressively with the amt. of added glucose. Temp. affects the quantity of O_2 absorbed but is practically without any effect on the amt. of H_2O_2 formed. Although reaction III would seem to indicate that H_2O is dispensible, nevertheless H_2O is actually indispensible for H_2O_2 formation. Expts. were carried out with various sensitizers (chlorophyll, eosin or hematoporphyrin) with and without an oxidizable substance (olive oil), in the presence and absence of H_2O. Only in the presence of H_2O did H_2O_2 appear on illuminating the system. In view of these expts. it is suggested that reaction III should be represented as follows: $A + OH_2 + O_2 = AO + H_2O_2$.

S. Morgulis

The photolysis of azomethane and of azomethane-acetaldehyde mixtures. Francis F. Blacet and Alvin Taurog. *J. Am. Chem. Soc.* **61**, 3024–7(1939).—The quantum yield of azomethane decompd. by λ 3660 A. at room temp. and in the pressure range 49 to 80 mm. has been found to be 1 and 0.75 when calcd. on the basis of the no. of mols. of free N formed per quantum absorbed and on the basis of the pressure increase, resp. Azomethane will photosensitize the decompn. of AcH when the ratio of AcH to azomethane is greater than 10 to 1. This is interpreted as meaning that free Me radicals produced in the photolysis of azomethane will react with either azomethane or AcH, preferably with the former.

A. B. Garrett

Quantum yields and kinetics of a photosensitized production of reducing sugars from sucrose in aqueous solutions of uranyl sulfate by visible and ultraviolet light. Lawrence J. Heidt. *J. Am. Chem. Soc.* **61**, 3223–9 (1939). —Quantum yields, ϕ, were calcd. as mols. of sucrose decompd. per photon absorbed by the system. The variation of ϕ with the concn. of sucrose was given by $\phi = a[1 - \exp(-g\,[\text{sucrose}])]$. The value of ϕ increased when the solns. were not buffered but is independent of the light intensity over a 200-fold range, the temp. between 10 and 35°, the pH between 3 and 6 and the concn of uranyl sulfate between 0.0008 and 0.008 molar. Beer's law was obeyed. The kinetics of the reaction are discussed.

A. B. Garrett

Relation between absorption spectra in the ultraviolet and the constitution of org. compds. (Dimroth) **10**. Formation of 3-indoleacetic acid by ultraviolet irradiation (Berthelot, *et al.*) **10**. Degradation of oriented cellulose structures by polarized ultraviolet light (Mason, Rosevear) **23**. Chemistry of vitamin E—absorption spectra of tocopherols, chromans, coumarans and related compds (Webb, *et al.*) **10**. Magnetic properties of the compds. ethylisocyanide-ferrohemoglobin and imidazole-ferrihemoglobin [absorption spectra] (Russell, Pauling) **11A**. Photochem. production of reducing sugars from glycosides by ultraviolet light (Heidt) **10**.

Atomic disintegration. Auergesellschaft A.-G. Brit. 508,233, June 28, 1939. In carrying out nuclear reactions, the energy requisite for activating the elementary particles participating is produced in a gas discharge under a mean gas concn. of more than 10^{19} mols. per cc., in which energies of 100 w.-sec. and more are dissipated during intervals of 10^{-6} sec. and less, corresponding to momentary outputs of 10^6 kw. and more. The concn. is preferably that corresponding to a pressure of 1 atm. at 18°. Neutrons are produced by a discharge in D, alone or mixed with H. He is produced by a discharge in Li vapor mixed with H; 2 isotopes are produced. A neutron-producing reaction may take place in a vessel lined with a B compd., e. g., $B(OCH_3)_3$.

Red-fluorescent material. The British Thomson-Houston Co. Ltd. Brit. 507,639, June 19, 1939. The material, more particularly for use with discharge lamps, comprises heat-treated MgO, SiO_2 and an activator such as Mn, prepd. by mixing the finely divided oxides in mol. proportions with addn. of less than 2% of a Mn compd., e. g., oxide, nitrate or carbonate, and firing at about 1250° or less for 1 hr. or longer. The material may be applied to the interior of the envelope of a low-pressure discharge tube filled with rare gas, e. g., A, Kr, Ne, Xe, at a pressure of 1–10 mm. Hg. It may be attached by a bond such as glycerol (I), a mixt. of I and H_3BO_3, K silicate, castor oil, or H_3PO_4, or may be embedded in the glass by heating this to the softening temp.

4—ELECTROCHEMISTRY

COLIN G. FINK

Evolution of the electric arc furnace in metallurgy. R. Berr. *Usine* **48**, No. 36, 23(1939).—Progress in elec. arc furnaces is seen not so much in the type (which is still the old Héroult principle) but mainly in the improvement of refractories for lining and in the roof, as these have to stand 3000–3500°. Silica and chrome-magnesite bricks for the roof are now preferably employed; for bottom and supports siliceous and magnesite products mixed with dolomite are used to give them sufficient thermal resistance against repeated shutting down and heating up. Three principal types of electrodes are used: amorphous carbon, Acheson graphite and Soderberg electrodes; the last two are the more common. The great advantage of elec. steel furnaces lies in improved steel quality, diminished oxidation and diversity of products. In Scandinavia, elec. arc furnaces are used also for the smelting of Fe ore, reduction being made with coke with part of the ore added in powder form. Energy consumption is about 2300 kw.-hrs./ton for acid open-hearth steel, and 2800–3000 kw.-hrs. for pig iron rich in Si. The gas produced in this process is rich in CO and has a heating value of about 2500 cal./cu. m.

M. Hartenheim

Electrolytic preparation of molybdenum phosphides. Jean Lucien Andrieux and Marcel Chêne. *Compt. rend.* **209**, 672–4(1939); cf. *C. A.* **32**, 3269⁴.—Varying proportions (1–20%) of MoO_3 dissolved in molten (800°) $NaPO_3$ to which about 6% NaCl was added were electrolyzed in a C crucible which formed the anode, a rod of C being the cathode, for 15 min. with a current of 15 amp. and 12 v. (c. d. at cathode 0.2 amp./sq. cm.). On cooling, the cathode product was dissolved in HCl aq. when crystals remained undissolved. Their compn. was MoP_2 (Hartmann, *et al.*, *C. A.* **31**, 8384⁸) and PMo_3 according as the bath contained not more than 4% or 11–20% of MoO_3. With more MoO_3, MoO_2 was formed. PMo_3 has d. 6.7 and, like PMo_2, forms fine metallic needles not attacked by HCl but readily so by HNO_3, less so by H_2SO_4, also by molten alkali or oxidizing material.

C. A. Silberrad

Comments on the paper of S. Pletenev and V. Rozov: "Cathode polarization during the electrolysis of fused salts." S. Karpachev. *J. Phys. Chem.* (U. S. S. R.) **13**, 147(1939); cf. *C. A.*, **33**, 3699⁶.—K. contends that the criticism of P. and R. against older methods of measuring cathode polarization is not valid. Cf. K. and Poltoratskaya, *C. A.* **30**, 7045⁹. **Reply.** S. Pletenev. *Ibid.* 148.—P. defends his views, and contends that K. and P. measured not the polarization but the change of potential of the C electrode in their expts. with molten $PbCl_2$.

F. H. Rathmann

A theory for the passivity of chromium. Sister M. Aida Ryan and Herbert Heinrich. *Trans. Electrochem. Soc.* **77**, 20 pp.(preprint)(1940).—In an attempt to discover the true cause of the phenomenon of passivity, numerous Cr electroplates were produced, exposed to various conditions and then tested for their activity. The theories that have previously been advanced do not

take into consideration the behavior of Cr under all of the conditions imposed upon the metal in the authors' expts.; therefore, a theory based on the electronic structure of Cr has been formulated: The atoms on the face of each unit cube of Cr share the electrons in their outermost orbits in such a way as to bring about a stable condition. To this complementary relation is attributed passivity of the metal. C. G. F.

Determination of thickness of electrodeposited chromium. M. M. Beckwith. *Monthly Rev. Am. Electroplaters Soc.* **26**, 769–75(1939).—B. recommends Clarke's modification of the drop test for the thickness of Cr. This test consists in placing a drop of a reagent composed of 20 g. of Sb_2O_3 dissolved in 1 l. of HCl (sp. gr. 1.16) on the Cr-plated surface, and noting with a stop-watch the no. of sec. required for the Cr to dissolve, as indicated by the beginning and cessation of gas evolution. Sb deposits during the test and is said to render the end point sharper. Graphs are given for converting the no. of sec. to coating thickness. The rate of soln. of Cr increases with the temp. At 75–80° F. each second of time is equiv. to 0.000001 in. thickness of Cr. A. Brenner

Current density range characteristics—their determination and application. R. O. Hull. *Monthly Rev. Am. Electroplaters Soc.* **26**, 753–67(1939). The presence of impurities in a plating bath or the effect of brightening agents can be ascertained by examg. the deposits over a range of c. d. A method is described for checking the performance of a plating bath over a wide range of c. d. in a single expt. The app. consisted of a plane cathode and anode in a rectangular plating cell. The anode was at one end of the cell. The cathode was at the other end of the cell and was inclined at an angle to the anode. The c. d. over the cathode was not uniform but varied from about 140 amp./sq. ft. on the projecting part to less than 5 amp./sq. ft. in the vertex of the angle formed by the cathode and the side of the cell. The current distribution over the cathode was detd. by plating Cu or Ni on the cathode. The latter was then cut into strips and the metal on each strip detd. Another method employed consisted in measuring the current through a test strip which was placed in different positions along the cathode. For app. of the specified size, graphs are given showing the current distribution over the cathode for various plating baths; they permit the c. d. at any point on the cathode to be detd. within 5–8 amp./sq. ft. The plating bath which is to be exaind. is placed in the cell and the cathode plated for 10–15 min. The different types of deposits, such as bright, dull or burnt, which are characteristic of different c. d. ranges, are obtained as vertical bands on the cathode. A. Brenner

Bright-silver electroplating. Robert Weiner. *Z. Elektrochem.* **45**, 743–50(1939). A crit. review of the methods proposed for the production of bright electrodeposits of Ag. S. Glasstone

Alkali cleaning as it affects the plating industry. L. C. Camel. *Monthly Rev. Am. Electroplaters Soc.* **26**, 777–85 (1939).—A review. A. Brenner

Electrolytic polishing. W. C. Elmore. *J. Applied Phys.* **10**, 724–7(1939).—The complicated voltage-current relations involved in the Jacquet method (*C. A.* **30**, 2115[4]) for electrolytic polishing of Cu are studied. It is concluded that when conditions are right for polishing the concn. of dissolved Cu at the anode is the highest possible, so that the rate of soln. is controlled entirely by the concn. gradient. As there is greater diffusion from raised areas of the anode because of steeper concn. gradients near them, the surface becomes progressively more nearly level. Details are also given for the electrolytic polishing of Fe with a H_3PO_4 electrolyte. A. O. Allen

Irreversible electrode phenomena of thallium. I. Hydrogen overvoltage in sulfuric acid. I. Milton LeBaron and A. R. Choppin. *Trans. Electrochem. Soc.* **77**, 12 pp.(preprint)(1940).—The overvoltage of Tl in H_2SO_4 solns. was detd. A wide variation in concn. and in temp. was used. A neg. temp. coeff. of about 0.0032 v. was found. No mechanism is proposed, but the data are applied to the math. derivations of Bowden (*C. A.* **24**, 1039). C. G. F.

Electrolytic reactions at the anode as the effect of the hydroxyl. Alfons Klemenc. *Z. physik. Chem.* **A185**, 1–36(1939).—Oxidation at the anode is ascribed to the action of primary charged hydroxyl, free diffusion of which is assumed. A Pt anode is considered as an O_2 electrode, the potential of which is 1.237 v. at 18° detd. from the free energy of the O_2-H_2 reaction. The primary anode process in the electrolysis of water is the discharge of the OH^-. The free OH formed is similar in electron structure to the F atom and its chem. reactivity is similar to that of F. The kinetics of the compd. PtO_{2n} on the anode is discussed along with the problem of overvoltage. Oxidation of hydroquinone at potentials above and below the point of generating O_2 is discussed as well as the temp. dependency of anodic oxidation. The oxidation of H_2SO_4, H_2SO_3, Na thiosulfate, aliphatic acids and ester acids and the monomeric behavior of persulfates and of hydroperoxides are also discussed. Victor R. Deitz

Cathode polarization of nickel. O. Esin and M. Loshkarev. *J. Phys. Chem.* (U. S. S. R.) **13**, 186–93 (1939).—Exptl. data for the overvoltage of Ni in an air-free system are given for $NiSO_4$ solns. from 0.4 to 2.0 *N* at temps. from 0 to 60°, current strengths of 0.03 to 29 milliamp. and with saddns. of acetate, borate, NH_4^+ or OH^- ions. F. H. Rathmann

Overvoltage in the electrodeposition of mercury on tantalum. I. M. Malkin. *J. Phys. Chem.* (U. S. S. R.) **13**, 194–9(1939).—The electrodeposition on Ta previously treated with HNO_3 of Hg from an acetate soln. was studied alone and in the presence of iso-amyl alc. and butyric acid. No definite relation could be found between overvoltage and surface tension on the Hg-soln. interface, but a definite relation to the shape of the Ta electrode was shown. From the exptl. data M. concludes that the overvoltage is due to delayed discharge in accord with the theory of Erdey-Grúz and Volmer (cf. *C. A.* **26**, 1197). F. H. Rathmann

Effect of air on the hydrogen overvoltage of cadmium. M. Straumanis and N. Brakss. *Z. physik. Chem.* **A185**, 37–44(1939).—The H overvoltage curve for Cd upon admission of air to a 0.1 *N* H_2SO_4 was investigated. The overvoltage is lowered by O_2 but only in the low c. d. range. For c. ds. of about 0.3 milliamp./sq. cm. the measured potential is partly dependent on the c. d., $\epsilon = e(I - a_1)/b_1$. However, if the O_2 for the oxidation of the H generated no longer suffices, the curve becomes exponential, $\eta = a + b \log I$. Victor R. Deitz

Influence of hydrated aluminum hydroxide on the overvoltage of hydrogen. F. A. Manusova. *J. Phys. Chem.* (U. S. S. R.) **12**, 647–52(1938).—The curve $\eta/\log I$ for the H overvoltage on a smooth Pt electrode in solns. of H_2SO_4, $Al_2(SO_4)_3.18H_2O$, NaOH and $NaAlO_2$ obeys Tafel's equation with b = 0.10–0.13, 0.25–0.30, 0.16–0.17 and 0.25–0.30, resp. The value of b, when colloidal Al is present, is considerably higher than required by the theory for a delayed discharge. M. suggests that the theory of Volmer and Erdey-Grúz (cf. *C. A.* **25**, 452) is applicable if allowance is made for the change in the electrode surface produced by the colloid. F. H. R.

Application of the theory of absolute reaction rates to overvoltage. H. Eyring, S. Glasstone and K. J. Laidler. *J. Chem. Phys.* **7**, 1053–65(1939). G. M. Petty

Electrolytic migration in metallic surfaces. Karl E. Schwarz. *Z. Elektrochem.* **45**, 712–14(1939); cf. *C. A.* **28**, 5731[4].—Under a potential gradient of about 0.2 v./cm. metallic Po, deposited on the surface of a fine Ag wire cleaned in HNO_3 or H_2SO_4, migrates to the anode at 350–400°. The rate of migration increases as the temp. is raised. The movement is sensitive to slight changes in the Ag surface owing to etching or to impurities. S. Glasstone

Chemical behavior of hydrogen and nitrogen in the glow discharge with a graphite electrode not previously outgassed. Reino Näsänen. *Suomen Kemistilehti* **12B**, 19–20(1939) (in German).—If the electrode contains O, the discharge even in H forms carbon oxides, no hydrocarbons

being recognizable. In N a brown ppt. is formed, which could not be identified. Gregg M. Evans

Oxidation of a graphite electrode in highly rarefied water vapor. V. Sihvonen and R. Näsänen. *Suomen Kemistilehti* **12B**, 25–6(1939) (in German).—In H_2O vapor the primary product is CO. This is further oxidized by the H_2O. Gregg M. Evans

Preparation of acetylene in the interrupted discharge. M. Ya. Kushnerev and A. B. Shekhter. *J. Phys. Chem.* (U. S. S. R.) **13**, 259–66(1939).—On passing an impulse discharge through anthracene oil, a gas contg. 22–30% C_2H_2 is obtained. The energy required is 11–12 kw. per cu. m., and is practically independent of the capacity from 5.10^{-6} μF. to 0.25 μF. F. H. Rathmann

---

Prepg. steel bumper bar for Ni and Cr plating (U. S. pat. 2,173,092) 9. Alloys for elec. leading-in wires (U. S. pat. 2,172,148) 9. Complex metal amine salts [for electroplating processes] (U. S. pat. 2,173,823) 10. Impregnating compns. [for elec. purposes] (Brit. pat. 507,855) 12. Sealing leading-in conductors into ceramic material (Brit. pat. 506,530) 19. Sealing leading-in conductors into vitreous material (Brit. pat. 506,469) 19. Sealing leading-in wires through walls of vitreous envelopes (Brit. pat. 506,562) 19.

Storage batteries. Henri G. Andre. Brit. 506,731, May 23, 1939. Addn. to 491,782 (*C. A.* **33**, 1222[3]). The grids or screens for receiving deposited metal in the battery of 491,782 are made of flattened strips that are arranged normally to the surface of the adjacent neg. electrode except at the points where they cross, where they are oblique.

Storage-battery electrolytes. Max Hartmann. Brit. 507,035, June 8, 1938. These are made by adding to hydrated silica, contg. approx. 86% H_2O, sufficient concd. H_2SO_4 to produce a paste contg. 30–32% H_2SO_4. The paste is then allowed to swell or ripen, during which process more 30–32% H_2SO_4 may be added. Ripening may be accelerated by the passage of a weak elec. current and terminated by the addn. of $MgSO_4$ and (or) by heating to 60–90°. To diminish self-discharge of the finished cell, about 0.1% of $BeSO_4$ may be added during the ripening.

Grid-like separators for batteries. Josef Grabec and Adalbert von Ledofsky. Brit. 507,117, June 9, 1939. The horizontal and vertical members of the separators are of rounded or triangular form to provide line contact with the adjacent electrode.

Electrical rectifier. Richard A. Hartley and Craig M. Bouton (to Union Switch & Signal Co.). U. S. 2,172,887, Sept. 12. An asymmetric unit is used consisting of a Cu disk having a layer of Cu oxide formed on one side, with which is brought into contact an electrode consisting of a mixt. of fibrous material such as cellulose fiber and cond. material such as a pulverized metal.

Dry rectifiers. Patentverwertungs G. m. b. H. "Hermes." Brit. 508,177, June 27, 1939. These have tubular units such as Cu tubes with an outer layer of Cu_2O covered by a coating of Zn, the outsides being insulated from one another by a moisture-repelling insulating medium.

Dry-plate rectifiers. The British Thomson-Houston Co. Ltd. Brit. 508,180, June 27, 1939. Addn. to 497,034 (*C. A.* **33**, 3707[2]). The method of 497,034 is modified in that the treatment to which the light metal base is subjected takes place with the use of C as the material for the deposit, the electrode being preferably placed for a short time in the vicinity of a C arc burning under reduced pressure.

Copper oxide rectifiers for alternating currents. Roger H. Cubitt (to Union Switch & Signal Co.). U. S. 2,172,576, Sept. 12. In making a Cu oxide rectifier, a Cu blank is subjected to an oxidizing temp. to form an oxide layer on it, then exposed to cold air for about one min., in order to facilitate the process, and then subjected to an annealing temp.

Single-phase mercury-cathode rectifier. Johannes G. W. Mulder (to N.-V. Philips' Gloeilampenfabrieken). U. S. 2,173,023, Sept. 12. Various structural details.

Electroplating articles of aluminum, magnesium and their alloys. Langbein-Pfanhauser-Werke A.-G. Brit. 507,342, June 14, 1939. The articles are coated with a nonconductive lacquer or varnish, preferably of neutral reaction, on which a conductive layer, e. g., of Ag, is then deposited by treatment with reducible metal salt solns.; the metallized surface is then electroplated, e. g., with Cu from an acid bath. Ni or Cr may be finally deposited. The article may be roughened, e. g., by anodic oxidation in a H_2SO_4 bath, before application of the lacquer.

Depositing metals by electric discharge. Bernhard Berghaus. Brit. 508,278, June 28, 1939. In metallizing metal articles, the cathode is cooled and the input of energy is such that the articles, which may form the anode or may not be connected to any source of potential, acquire a temp. of at least 300°. Thus, a Cu article is degassed, cleaned and heated for 5 min. to 950° by cathodic bombardment in H, a slight deposition of Ag from the cathode accompanying the heating; subsequently, the gas pressure is increased, e. g., to 2–3 mm., and the loading is adjusted so that the article is heated to 800° and Ag is deposited; the Ag alloys with the Cu; after 30 min., the temp. of the article is reduced to 600° and then slowly to 400° to form a layer of pure Ag. In another form, the Ag is deposited at a temp. at which it only diffuses into the surface and the alloy is not formed, the article being heated subsequently to form the alloy. Cf. *C. A.* **33**, 3705[4].

Separating plating from iron. Metallgesellschaft A.-G. (Max Wohlwill, inventor). Ger. 679,931, Aug. 18, 1939 (Cl. 40b, 1). Nonferrous heavy metals or alloys are removed from Fe or steel plated with them, by making the Fe or steel plate the anode in an electrolytic bath of a nitrate or nitrite, preferably of an alkali- or alk.-earth metal or of Mg, and having a porous diaphragm sepg. the anode and cathode. Thus, Fe coated with Cu or Zn is electrolyzed in $NaNO_3$ soln. to dissolve off the Cu or Zn.

Recovering tin from stannic chloride. Jesse O. Betterton and Yurii E. Lebedeff (to American Smelting and Refining Co.). U. S. 2,173,268, Sept. 19. App. is described, and a process for recovering Sn from $SnCl_4$ which involves adding sufficient water to the $SnCl_4$ to produce an electrolyte therefrom while avoiding production of solid products of hydrolysis, placing the resulting electrolyte into an electrochemical cell including a metal electropositive to tin as an anode and a metal electronegative to tin as the cathode, enclosing the anode in a permeable diaphragm for retaining solid materials sepd. from the anode, electrically connecting the anode and cathode to form a shorted cell and allowing the tin to ppt. at the cathode as a sludge.

Zinc dust. I. G. Farbenindustrie A.-G. Brit. 506,590, May 30, 1939. See Ger. 677,992 (*C. A.* **33**, 9159[3]).

Copper-calcium alloys. Siemens-Schuckertwerke A.-G. Brit. 506,922, June 7, 1939. The electrodes of a spark-gap, particularly for use in a converting system, are constructed of a Cu-Ca alloy to reduce the voltage drop across the gap during operation. The gap is preferably surrounded by A, Xe, Kr, He or like medium, for the same purpose.

Apparatus for extracting or concentrating, by electrolysis, elements in solution or in suspension in liquids. Jules W. A. Convert and Pierre P. J. F. Mommen. Brit. 507,397, June 19, 1939. The app. is provided with electrode chambers, the filtering walls being completely immersed and being disposed at or near the base of these chambers, combined with means for the withdrawal of liquid from inside the chambers to set up a hydrostatic pressure across the filtering walls toward the electrodes. Back diffusion may be restricted by the provision of intermediate compartments, and the filtering walls that delimit the said compartments may have surfaces that are different and calcd. to assist in regulating the flow of the liquids.

Electrodes for arc converters, electric welding, etc. Allgemeine Elektricitäts-Gesellschaft. Brit. 507,757,

June 16, 1939. These consist of an alloy of 2 or more metals and are operated in a mixt. of gases 1 of which attacks 1 of the constituents of the alloy to form a thin coating on the surface of the electrode, which reduces disintegration of the electrode and improves the burning of the arc. Thus, the electrode may consist of a eutectic mixt. of Cu and Ag burning in a mixt. contg. O; the Ag acts as an O carrier and produces a coating of sep. layers of the 2 oxides of Cu.

Carbon electrodes and other articles. Walter A. Cloud. Brit. 508,008, June 23, 1939. C for electrodes, etc., is made by mixing finely ground anthracite coal having a fixed C content of approx. 90% and 1% ash, bituminous coal, calcined flame lampblack and petroleum still coke with coal tar and (or) pitch as a binding agent, reducing the mixt. to a plastic mass by heat, molding or extruding the mass to the desired shape and then baking the articles, the process being initiated at 212°F. and conducted thereafter at a gradually increasing temp. up to about 2000°F. For a softer grade of C, caramel from cane sugar or carbonized sugar may be used as a binder instead of the tar or pitch and, if desired, foliated graphite may be incorporated in the mixt.

Electrode system of unsymmetrical conductivity. Gilles Holst and Willem C. van Geel (to N.-V. Philips' Gloeilampenfabrieken). U. S. 2,173,904, Sept. 26. An electrode system for the detection or amplification of elec. currents comprises a pair of main electrodes in spaced relation, one of which has a high emitting capacity and is made of Ag, Cu or Al, and the other of which has a low emitting capacity and is made from Se, a plurality of control electrodes also in spaced relation interposed between the main electrodes, and thin layers of insulating material interposed between and coming into contact with the surfaces of adjacent control electrodes and the surfaces of adjacent main and control electrodes.

Electrode materials. Siemens & Halske A.-G. Brit 507,589, June 13, 1939. A secondary electron-emissive material consists of 1 or more of the sulfides, oxides or selenides of the alk. earth metals mixed with not more than 0.1% of a finely divided metal such as Cu, Bi, Pb, Mn, Ni or Sb. The material is similar in compn. to known Lenard phosphors but with 2–3 times as much heavy metal. Preferably, not more than 10% of a fusible flux, e. g., Li, Na or K phosphate, NaCl, KCl, MgF_2, NaF or CaF_2, or mixts. of these, is added. If the alk. earth oxide is added as hydroxide, the flux may be dispensed with. The emissive material may contain up to 50% of alk. earth sulfates, carbonates or nitrates as diluents. The mixt. is prepd. in aq. or alc. soln., any insol. compds. being ground up or pptd. so as to be capable of suspension or reduced to colloidal form, e. g., a colloidal soln. of $CaCO_3$ is prepd. by passing CO_2 through a suspension of CaO in MeOH.

Electrode materials. Electrical Research Products, Inc. Brit. 508,995, July 10, 1939. In prepg. photosensitive surfaces for discharge devices by oxidizing a Ag or Cu surface that is afterward treated with Cs vapor, the O is supplied in the form of moist O_2.

Electrode for use in liquids for control of a pump, etc. Robert D. McIntosh (to Imperial Brass Mfg. Co.). U. S. 2,174,109, Sept. 26. Various structural details.

Alloy electrodes for electric discharge devices. Jan H. de Boer and Gottfried B. Jonas (to N.-V. Philips' Gloeilampenfabrieken). U. S. 2,172,967, Sept. 12. A gas-free electrode which sets free substantially smaller quantities of gas than Ni when heated in a vacuum is formed of Ni alloyed with Zr 0.05–3.0%. U. S. 2,172,968 relates to the like use of an alloy of Cu with a small proportion of Zr.

Electrodes for gaseous discharge devices. Jean Lecorguillier (to Soc. anon. pour les applications de l'électricité et des gaz rares établissements Claude-Paz & Silva). U. S. 2,173,208, Sept. 19. An electrode for gaseous discharge devices comprises 2 ribbons, one of refractory metal such as Ta and the other of a Pt or Ni group metal, alternate layers of which are sepd. by a layer of emissive material such as BaO_2 (various structural details being described).

Cleaning the surfaces of etched electrodes, particularly electrodes for electrolytic condensers. Siemens & Halske A.-G. Brit. 508,075, June 22, 1939. Electrodes that are roughened by etching to increase their effective surface area are cleansed by connecting the electrode as a cathode in a cleaning electrolyte liquid that is substantially free from constituents of the etching bath used prior to the cleansing. Preferably, the cathode and anode are sepd. by a suitable diaphragm, and the process may be supplemented by a further washing both of anode and cathode spaces with a liquid free from foreign ions, e. g., distd. H_2O, glycerol, glycol. The ions removed from the electrolyte surface may be removed by a colloidal or colloidal-chem. process, which may comprise, if the acid used for etching is HCl, (1) chem. deposition of the Cl ions freed by the cleansing, (2) conversion of added substances to complex compds. by the freed ions, (3) conversion of substances of ionic character into nonionic substances or (4) absorption of the freed ions and sepn. into flocculent form by means of colloids. Process (1) may be conducted by adding an appropriate salt or compd. to the bath, e. g., Ag_2O, $HgNO_3$, $Pb(NO_3)_2$ or $(AcO)_2Pb$ to ppt. AgCl, HgCl or $PbCl_2$, or by use of a counter-electrode of an appropriate metal, e. g., Ag, Sb, Pb or Bi to give AgCl, SbOCl, $PbCl_2$ or BiOCl; process (2), by adding $PtCl_4$, $Cr(OH)_3$, Pd NH_4 chloride or $PdCl_2$; process (3), by adding to the anode compartment benzene diazonium hydroxide, which is converted to benzene diazonium chloride by the freed Cl ions, which immediately loses N to give PhCl; and process (4), by adding colloidal $Fe(OH)_3$, $Al(OH)_3$, $Cr(OH)_3$, TiO_2 or ZrO_2. Diaphragm materials specified are leather, parchment paper, viscose and cellophane.

Electric condensers. Siemens & Halske A.-G. Brit. 507,242, June 7, 1939. In condensers wherein the dielec. consists of sheets of a polymerized vinyl compd., the condenser is sealed against moist air by being dipped in or brought into contact with a suitable liquid that has a solvent action on the polyvinyl compd., the product of this action being subsequently consolidated by the driving off of the volatile constituents or by polymerization. Suitable liquids may be pure solvents, e. g., Me_2CO, or unsatd. solns. of polymerizable products, e. g., a soln. of polystyrene in styrene.

Electric condensers. Standard Telephones and Cables Ltd., Thomas R. Scott and Archibald A. New. Brit. 508,057, June 26, 1939. These are prepd. having as insulator, preferably in tape form, a mixt. of a solid polymerized olefin, such as polystyrene, polyisobutylene or polyethylene, and finely comminuted inorg. particles having a permittivity greater than 5. Mica, marble, Iceland spar, $PbCO_3$, rutile, AgCl, AgBr, zircon, cassiterite, pyromorphite, HgCl, corundum, cerussite, Rochelle salt, PbO, Tl chloride, Tl bromide, CuO, sintered Al_2O_3, quartz, fused SiO_2, com. steatite, ultrasteatite and fused TiO_2 are specified. Examples are given of mixts. contg. polystyrene, rubber and ceresin wax with mica, Iceland spar, rutile or $PbCl_2$.

Apparatus and method for treating articles with liquids. Robert Barlow and Peter Renold. Brit. 508,384, June 29, 1939. An article, e. g., a can end, the surface of which is to be treated with a liquid is mounted on a chuck and is lowered into contact with the surface of the liquid which is supplied to a tray by a central pipe and overflows over its walls. The treatment may comprise electroplating, electrophoretic deposition of wax or lacquer, anodic oxidation or electrolytic cleaning, the chuck and tray being in these cases insulated and appropriately connected as electrodes. Alternatively, the treatment may comprise coating with lacquer by contact with the lacquering liquid.

Luminous signs with translucent display characters of methyl methacrylate resin. James Penoyer. U. S. 2,173,371, Sept. 19. Various details.

Electrical resistance units of materials such as tinned copper. Torrence A. Swartz and Wilmer P. Uhler (to The S. S. White Dental Mfg. Co.). U. S. 2,173,186, Sept. 19. Various structural and mfg. details.

Electrolytic recording paper suitable for use with telegraphic apparatus, etc. Paul Talmey (to Radio Inventions, Inc.). U. S. 2,173,141, Sept. 19. A supporting sheet is used of material such as paper contg. a substantially insol. oxyhalide of Sb or Bi, such as $Sb_4O_5Cl_2$, and also contg. a soln. of an electrically conducting compd. such as KCl in sufficient quantity to render the sheet conducting.

Electric fusible lead for fuses. Eduard Grünwald (50% to Helmut Lenk). U. S. 2,173,200, Sept. 19. A body of Mg is used with a surrounding shell of good elec. cond. and contacting metal such as Cu in intimate contact with the Mg along its entire length.

Asymmetric electrode system for photoelectric cells. Jan H. de Boer and Willem C. van Geel (to N. V. Philips' Gloeilampenfabrieken). U. S. 2,173,249, Sept. 19. Bi 1.5 and I 3.0%, based on the wt. of Se used, are mixed with equal quantities of melted amorphous Se, forming a compd. of Bi iodide in the Se, and the mixt. is applied to a metal base such as brass or to carbon as a coating of about 0.05 mm. thickness, cooled for solidification, and then heated to about 200° for a suitable time (which may be about 10 hrs.) to convert the amorphous Se to the cryst. form; an insulating coating such as polystyrene is applied to the Se coating, and a conducting coating such as Wood metal is applied to the insulating coating.

Active metal compound suitable for "getters" of vacuum tubes. Ernest A. Lederer (to Radio Corp. of America). U. S. 2,173,258, Sept. 19. As a source of Ba free of products of decompn., a product of Ba and Be chemically combined with O is coated upon a refractory core such as one of Ta, W, Mo, Ti or V which is capable of reducing the Ba-Be compn.

Active metal compounds suitable for "gettering" of vacuum tubes. Ernest A. Lederer (to Radio Corp. of America). U. S. 2,173,259, Sept. 19. A source of Ba comprises a core of Fe, Ni, Cb, chrome iron, Ni-Fe-Cr alloy, Mo or W carrying a coating including O compds. of Ba and Be mixed with about 10% of powd. Al, Cb, W, Mo, Th, Ta or Si.

Discharge lamps. The General Electric Co. Ltd. and Basil N. Clack. Brit. 507,519, June 16, 1939. In a Na vapor lamp, the electrodes are formed from a W wire of 0.1-mm. diam. wound upon a mandrel of 0.2-mm. diam. W wire, the whole being made into 2 concentric helices of stated turns and diams.; the helices are coated with a suspension of $BaCO_3$ and $SrCO_3$.

High-pressure metal-vapor electric discharge lamp. Victor J. Francis and John W. Ryde (to General Elec. Co.). U. S. 2,172,839, Sept. 12. A sheath contg. not less than 80% of ZrO_2 (and which may also contain MgO or ThO_2 and CaO) and which is permeable to light is interposed between a sealed envelope and the discharge path between thermionic electrodes, the sheath being pervious to the gaseous filling and serving to prevent deviation of the discharge from a substantially straight path between the electrodes.

Arc lamp cathodes. Le Carbone-Lorraine. Brit 509,291, July 13, 1939. A cathode for a high-intensity arc having an anode with a mineralized core of known type is provided with a core of C mixed with a compd. of an alkali metal not contg. O, e. g., a halide, fluoborate or fluosilicate; this inhibits the formation of carbides of the metals contained in the anode core, which carbides interfere with the burning of the arc. The compd. is preferably such that the core contains 1 atom of alkali metal to 2.5–7.5 of C.

5—PHOTOGRAPHY

E. R. BUI

Photographic "negative" material and light filters for "photomicrography." Hermann Schopf. *Phot. Korr.* **75**, 8–15(1939). E. R. Bullock

Hypersensitization. Georges Steenackers. *Photo* (Belgium) **6**, 85–7(1939). S describes the procedure in the methods of hypersensitizing by (1) bathing in NH_3 soln., (2) fuming with NH_3 vapor, (3) bathing in ammoniacal $AuCl_3$ soln. as recommended by Gevaert and (4) leaving, for a comparatively long time, over Hg in a closed container; and summarizes the results obtained. In the last case the treatment if given, alternatively, after the light exposure, intensifies the latent image. E. R. Bullock

Desensitization. E. Katsenelenbogen. *Sovet. Foto* 1939, No. 8, 28–9.—The most common photographic desensitizers are pinacryptol green and pinacryptol yellow. Both are produced in the U. S. S. R. *Pinacryptol green* is prepd. as dark-green crystals, which do not stain hands or emulsion, and do not affect the latent image or the time of keeping of developing solns. Too prolonged bathing in solns. of this desensitizer without immediate development tends to destroy the latent image. This soln. acts in proportion to its concn. After bathing a certain no. of films in pinacryptol green, the latter becomes exhausted. Solns. should be kept in the dark and not longer than 10 days. Foam which occasionally forms on the surface of these solns. must be removed before treating films. The presence of developing solns. greatly increases the action of this desensitizer. Dilns. up to 1:25,000 in metol-hydroquinone are more effective than that of 1:5000 in H_2O. Not all developers can be used. Modified Kodak and Agfa developing formulas with addn. of pinacryptol green are given. *Pinacryptol yellow* is a yellow powder, less cryst. than pinacryptol green. Its action on panchromatic film is greater than that of pinacryptol green. Since it is destroyed by Na_2SO_3, it cannot be used in developing solns. The film must be bathed in aq. solns. of the desensitizer prior to immersion in the developer. Films treated in 1:1000 solns. for 2 min. may be developed in yellow-orange light at a distance of 60–80 cm. Expts. showed that films could be developed in white light (10–15 w. at 50-cm. distance), if development was not longer than 2 min. W. R. Eichler

Empirical relations between sensitometric and size-frequency characteristics in photographic emulsion series. A. P. H. Trivelli and W. F. Smith. *Phot. J.* **79**, 330–8 (1939).—A photographic emulsion series is defined, and a detailed description is given of the emulsion-making technique employed for these expts. A distinction is made between single-grain-layer and multigrain-layer coatings in exposure to (visible) light. In the latter case, the total projective area, as such, is not of primary importance. The av. thickness and the total surface, both derived from the total projective area, are important, however, in the study of grain development and physicochem. reactions on the sensitivity of photographic materials. The most important size-frequency characteristics are the av. grain size ($\bar{a}$), the total no. of grains per cc. of emulsion, and the standard deviation. The most important sensitometric characteristics are speed and gamma. From the data obtained, a series of equations was derived. They were of the exponential type in all cases except 3, in which a direct proportionality was shown to exist. The direct proportionality between the H. & D. speed (S) and the av. grain size, gives as $S/\bar{a}$ a measure of the av. sensitivity factor of the gelatin used in these emulsion series.

Authors

Empirical relations between Hurter and Driffield speed and average grain size of photographic emulsions. A. P. H. Trivelli and W. F. Smith. *Phot. J.* **79**, 463–8(1939); cf. preceding abstr. and *C. A.* **33**, 8513⁶.—An extended investigation concerning the direct proportionality between H. & D. speed and av. grain size shows that this relation holds for a wide range of grain sizes in which, in different emulsion series, the AgI content, the time of finishing the emulsion and the time of development were varied. The emulsion-making technique was the same as

that described in the previous paper. Deviations were found with pure AgBr emulsions having extremely large grains and with large grain Ag bromoiodide emulsions made with gelatin having a low sensitivity factor.

Authors

Image reversal on photobromides. Lüppo-Cramer. *Phot. Ind.* **37**, 919–22(1939).—L.-C. discusses in detail the phenomena of color adaptation or bleaching of light-darkened AgBr and of synthetic photobromides. He describes his own recent tests on the Arens' nitrite bleaching-out process (*C. A.* **34**, 37[1]), and points out that, because of the higher order of magnitude of the exposure necessary for the direct darkening in this case as compared with that for the 1st reversal of the latent image, the increase in particle size reported is not conclusive for the "coagulation" theory of ordinary solarization.

E. R. Bullock

Color print processes. II. Duxochrome. Geo. L. Wakefield. *Process Engraver's Monthly* **46**, 257–8(1939); cf. *C. A.* **33**, 4533[8], 9163[3].—A disadvantage of the Duxochrome process is that exposure is different for each of the 3 positives and the positives cannot be checked with a densitometer at an early stage as in Carbro or the Eastman Wash-Off Relief process. The tanning developer is somewhat unstable and any process using developed relief is apt to be uncertain. Fixing is not necessary. The process can give very rich prints, with brilliant colors, highly suitable for reproduction purposes. A. M.

The procyanines. I. Diquinolyls and procyanines: the 2,3′-quinoline-procyanines. E. Calzavara. *Science ind. phot.* **10**, 193–8(1939). A yellow base is obtained when quinoline is heated with $NaNH_2$. This is stated to be 1,2,3,4,1′,2′,3′,4′-octahydro-2,3′-diquinolyl, which C. calls "2,3-quinoline-procyanine." [This substance contains no acidic radical and is not a member of the cyanine dye series.] The base forms a brick-red hydrochloride. Various substituted derivs. are also described as well as a product derived from β-picoline and quinaldine. These bases sensitize both AgCl and AgBr emulsions and also can act as photographic developers. L. G. S. B.

Ultrarapid drying. Don M. McCutcheon. *Am. Phot.* **33**, 496, 498–9(1939).—Films can be rapidly dried without the support badly curling or the gelatin becoming damaged if heat rays are used which are absorbed strongly by the H_2O but only weakly by the film base. Suitable wave lengths lie between 0.6 μ and 5 μ. These are furnished by heater-type coils fitted with 0.5–1.0 mm. clear glass or by the use of standard C filament infrared lamps. Infrared-treated film dries 40–100% faster than untreated film. R. A. Purdy

The early scientific daguerreotypists. Luppo-Cramer. *Phot. Ind.* **37**, 177–8(1939).—Some account is given of the observations and opinions of Edm. Becquerel, Gaudin and Lerebours, F. Moser and Donné, with a short discussion of the actual nature of the latent photographic image.

E. R. Bullock

Densitometry of photographic paper positives. W. Falta. *Z. wiss. Phot.* **37**, 247–58(1938).

Hypersensitizing papers for speed and artistry. J. Kairow. *Am. Phot.* **33**, 321–2, 324(1939). The speed of contact paper can be increased 20–100%, and that of enlarging paper 80–225%, by treatment with Hg vapor. These speed increases depend on the kind of paper and the time of treatment. R. A. Purdy

---

Color photography. Geoffrey B. Harrison (to Ilford Ltd.). U. S. 2,173,110, Sept. 19. A method of producing pictures in color from exposed light-sensitive photographic material comprising two light-sensitive layers, the first arranged to record substantially only one of the three primary colors and contg. a latent color-sepn. record of that color and the second arranged to record the other two primary colors and contg. latent color-sepn. records of those two colors produced by exposure through a two-color screen the colors of which are respectively (*a*) one of the two primary colors other than that which the first layer is arranged to record and (*b*) the color complementary to (*a*) involves treating the first layer to convert the latent record into an image in color complementary to the color of which it is a record and treating the second layer to convert the latent records of that layer into an image in the color which was recorded by the first layer.

Color photography. I. G. Farbenindustrie A.-G. Brit. 507,009, June 7, 1939. Photographic material comprises a support carrying on 1 or both sides Ag halide emulsions of different sensitivity and contg. dye-formers, at least 1 of the emulsions being in the form of finely subdivided particles and at least 1 other in the form of a continuous layer. Two or more differently sensitized emulsions may be distributed as fine particles in a gelatin layer and 1 or more differently sensitized emulsions having different dye-formers may be arranged as continuous layers above this. Brit. 507,142, June 12, 1939. Uniform prints of multi-colored drafts or designs are prepd. by printing the colored original onto a photographic material comprising 1 or more Ag halide emulsions contg. dye components fast to diffusion and subjecting the material to color development. The components may be in emulsion layers arranged on 1 or both sides of a support or contained in a mixed-particle emulsion on a support. The dye components are described in Brit. 458,400 (*C. A.* **31**, 3405[5]), 465,823 (*C. A.* **31**, 7777[1]), 479,838 (*C. A.* **32**, 5320[4]), 483,000 (*C. A.* **32**, 7358[6]), 484,698 (*C. A.* **32**, 7358[9]), 489,093 (*C. A.* **33**, 603) and 489,274 (*C. A.* **33**, 612).

Color photography. Béla Gáspár. Brit. 507,151, June 9, 1939. Multilayer material comprises several differently sensitized Ag halide emulsion layers, at least 1 of which contains an image-forming dye that can be locally bleached by a Ag image, and at least 1 other layer arranged behind said colored layer contains a filter dye of the same color that is destroyable by a photographic developer. In the example, a paper support carries in superposition a blue-green layer, a magenta layer and a yellow layer, sensitized to red, green and blue, resp. The top layer contains Xylenewalkgelb G (I), the next layer contains Tuchechtbrillantrot 2B (II) and an auxiliary yellow dye 4,4′-methenylbis[1-(*p*-sulfophenyl)-3-methyl-5-pyrazolone], and the 3rd layer contains Pontamine sky blue 5BX (III) and, in addn., either the dye from 1-(*p*-sulfophenyl)-3-methyl-5-pyrazolone and β-anilinoacrolein-anil or the sulfonic acid derived from methenylbis[hydroxythianaphthene]. The material may be exposed behind colored or black and white pos. part images or behind a multicolor master positive, the auxiliary filter dye decolorized by use of a developer of alk. reaction, and the image-forming dyes destroyed at the image points by acid thiocarbamide soln. or 5% HBr. In Brit. 507,152, June 9, 1939, at least 1 layer of a multilayer sensitive material is dyed to a color d. higher than that required for accurate color reproduction by a dye that is fast to ordinary photographic treating solns. but capable of being locally bleached in the presence of metallic Ag, said layer comprising also either metallic or colloidal Ag or a Ag salt which is uniformly exposed or sensitized, e. g., to infrared, so that it can ultimately be exposed, for the purpose of removing the excess dye. In the example, the film comprises on 1 side of the support a blue-sensitive emulsion colored blue-green with III and on the other side a red-sensitized emulsion colored yellow with I and a blue-sensitized emulsion contg. the magenta dye II. The yellow dye is in excess of that required for correct image formation. The 2 other layers may also contain excess. Cryptocyanine may be used to sensitize the layers to infrared. The images and the exposed Ag salt are both transformed by dye destruction with either HBr or thiocarbamide soln. Brit. 507,211, June 9, 1939. An addnl. colloid layer that is mounted in front of 1 of several Ag halide emulsion layers in a color photographic material contains an acid dye of appropriate color and resistance to ordinary photographic treating solns. and an evenly distributed substance that assists in the bleaching of the dye by dye-destroying agents, e. g., finely distributed Ag, colloidal Ag, fogged Ag halide emulsion, exposed Ag halide or color-sensitized Ag halide. The Ag halide emulsion layer behind the colloid layer is sensitive to light that

is absorbed by the colloid layer but is sensitized to light transmitted by the latter. Among several examples, (1) a blue-sensitive layer in front of green- or red-sensitive layers contains the surplus yellow dye on the rear part, the emulsion in this part being exposed during the coating operation; the coating operation for each of the layers may be avoided by the formation of 2 sep. strata in a single dyed emulsion layer by surface illumination, and (2) the front element of a bipack has a blue-sensitive layer and a green-sensitive layer sepd. by an intermediate gelatin layer contg. Milling Yellow G and an amt. of exposed AgBr emulsion; after development and fixation, the element is dyed by being soaked in a 1% soln. of Pontamine Sky Blue and the dyes in the layers are then destroyed by acid thiocarbamide soln. or HBr and the Ag is removed by bleaching; the intermediate layer is consequently decolorized and the gelatin is tanned by the bleaching; the film is fixed and dried, and the upper layer treated with Na hyposulfite soln.; the decolorized upper layer is then colored at the unhardened places by a H$_2$O-sol. dye. Brit. 507,418, June 9, 1939. Multilayer material comprises at least 1 sensitive layer that is colored with a dye that transmits the light to which the layer is sensitized and absorbs the light to which the layer above it is sensitive and that is capable of being bleached by the Ag image, the layer contg. an addnl. dye of the same color, which is, however, totally removed by the treating solns. which are harmless to the image-forming dye. Alternatively, the addnl. dye is 1 of similar properties to the image-forming dye and is destroyed in the presence of finely divided Ag. The concn. of the 1st dye is sufficient for coloring the most intensely colored parts of the image while the concns. of both dyes are together sufficient to absorb all the light to which the front layer is sensitive. The auxiliary dye may be in a sep. colloid layer. In an example, a green- or red-sensitized emulsion dyed by a mixt. of Xylenewalkgelb and 4,4′-methenylbis[1-(*p*-sulfophenyl)-3-methyl-5-pyrazolone] is arranged between a blue-sensitive Ag halide emulsion layer dyed magenta with a salt of Tuchechtbrillantrot (I) and a blue-sensitive Ag halide layer dyed blue-green with Pontamine Sky Blue 5BX (II). The support may be adjacent 1 of the outer layers or between the layers. The dye is decolorized by an alk. developer or by sulfite or bisulfite compds. and the dye images are produced as in Brit. 415,040 (*C. A.* 29, 1339[1]). In a 2nd example, a support is coated with a Ag halide layer colored blue-green with a quinolinium salt of II and sensitized with Cryptocyanine for infrared light and contg. also a destructible dye obtained from 1-(*p*-sulfophenyl)-3-methyl-5-pyrazolone and glutaconic dialdehyde dianilide. The destructible dye may be in a sep. thin gelatin layer. An emulsion layer sensitized to red with pinacyanol and colored magenta with a quinolinium salt of I is coated directly on the blue-green layer. The magenta layer or a sep. layer lying above it contains a red dye which may be the diphenylguanidine salt of the sulfonic acid of methenylbis[hydroxythianaphthene]. A yellow-colored layer sensitized to green is coated above this layer. The auxiliary layers may be light-sensitive and the dyes therein destroyed after a diffuse illumination, which allows a sep. exposure of the auxiliary layers. Brit. 507,485, June 9, 1939. A multilayer light-sensitive material comprises a support carrying a plurality of superimposed Ag halide emulsion layers each differently sensitized and at least 1 of the layers contg. a dye that is fast to ordinary photographic treatment solns. but can be locally bleached in the presence of a Ag image and absorbs the light rays for which the layer is predominantly sensitized, another layer being arranged behind this colored layer and sensitive to these light rays so that a removable light filter dye of substantially the same color as the other dye is present in a layer in front of the 2nd dye but not in front of the 1st layer. The concn. of the image-forming dye is sufficient for the color intensity at the most intensely colored parts of the image. The filter dye may be one that is destroyed by the photographic developers and is included either in the 1st layer or in a sep. layer of clear colloid between the 2 layers. In the example, a paper support carries a blue-green emulsion sensitized to red light, a magenta-dyed emulsion sensitized to green and a yellow-dyed emulsion sensitive to blue. The top layer contains Xylenewalkgelb G in the form of its Ca salt, and in the same layer or in a sep. gelatin layer the yellow dye 4,4′-methenylbis[1-(*p*-sulfophenyl)-3-methyl-5-pyrazolone]. The magenta layer contains Tuchechtbrillantrot 2B as its methylnaphthoquinolinium salt and in the same or a sep. layer either the sulfonic acid derived from methenylbis[hydroxythionaphthene] or the red dye obtained from 1-(*p*-sulfophenyl)-3-methyl-5-pyrazolone and β-anilino-acrolein-anil. The next layer is panchromatic and contains Pontamine Sky Blue 5BX. The material is exposed behind colored or black and white pos. part images and the image-forming dyes are locally destroyed by an acid thiocarbamide soln. or 5% HBr, the other dyes being destroyed in the development.

Multilayer material for color photography. Béla Gáspár. Brit. 507,357, June 14, 1939. The material comprises at least 1 colored Ag halide emulsion layer that has a considerably lower sensitivity to the light absorbed by the dye in the layer and is used for the exposure of the superimposed layer or layers. In an example, 3 AgBr gelatin emulsion layers are arranged upon 1 or both sides of a transparent support, the middle-layer emulsion being unripened and having an inherent blue-sensitivity that is about 0.1 that of the other emulsion. The unripened emulsion is dyed yellow with an image-forming dye, which may be Chrysophenin G rendered insol. by treatment with triphenylguanidine lactate, and is sensitized to green with Erythrosin. The 2 outer layers are not specially sensitized and are dyed blue-green and magenta with Pontamine Sky Blue and Tuchechtbrillantrot 2B, resp. This material is used for printing, exposure being from both sides. If neither or only 1 of the other layers is colored, 1 of them may be sensitized to red, and in this case the support may be opaque with all the layers on 1 side and sepd. by clear gelatin layers, exposure being from the side of the blue layer. The dye images are prepd. as described in Brit. 408,991 (*C. A.* 28, 6074[6]).

Tone-and-color synthesis in color photography. Francisco G. Yanes. U. S. 2,173,490, Sept. 19. A cinematographic film is prepd. suitable for projection carrying four color sepn. positive part images of subtractive character provided with their corresponding pigments and representing the same subject, the part images so arranged in the film that one picture space shows a green and a magenta part image in register while the adjacent picture space shows a yellow and a blue-violet part image in register, and so in successive picture spaces of the film.

Fine-grain photography. John R. Weber (to Du Pont Film Mfg. Corp.). U. S. 2,173,739, Sept. 19. A method for producing a properly graded fine-grained photographic image comprises developing a latent image in a Ag halide emulsion to metallic Ag to a gamma not greater than approx. 0.5 with a color-forming developer comprising a photographic developing agent and a dye coupling component to form a dye image *in situ* with the Ag image and subsequently printing the combined Ag and dye image onto another sensitized layer.

Cinematography. Fred W. Jackman (to Warner Bros. Pictures, Inc.). U. S. 2,173,518, Sept. 19. App. is described, and a method of producing a cinematographic picture showing a tonal change of successive kinematic phases of action which comprises arranging portions of the action in different colors, simultaneously photographing the action upon two cinematographic films while suppressing the color value of one of the different colors as photographed upon one of the films, and prepg. a cinematographic picture by conjoining successive images of a portion of the action on one of the films wherein the color [illegible] suppressed [illegible] portion of the action on the other of the films wherein the color value is not suppressed.

Producing fractional density combinations between differing aspects of a scene in cinematography. Ivan M. Terwilliger. U. S. 2,173,866, Sept. 26. A method of printing a positive film strip from a negative film strip

bearing on successive frames the variant component images of stereoscopic image sets comprises printing the images on the negative to partial d. on the positive film strip, and varying the quantity of printing light such that the ds. of successive images so printed on the positive alternate between two values, then again printing the positive film strip from the negative, but with the positive shifted an integral number of frame lengths with reference to the negative, whereby slightly differing images become superposed on the positive, and in such second printing, so varying the quantity of printing light that the images on the negative are printed to partial ds. on the positive, whereby the positive frames receive superposed component images in partial ds., making up successive composite images of substantially normal densities.

Stabilizing photographic sensitive materials. John D. Kendall (to Ilford Ltd.). U. S. 2,173,628, Sept. 19. As fog inhibitors for light-sensitive Ag halide gelatin emulsions, use is made of 2-amino-4-hydroxy-pyrimidine, alkyl, aryl, aralkyl and arylene substituted 2-amino-4-hydroxy-pyrimidines or their tautomeric compds. or salts.

Oxazole trimethinecyanines. Wilhelm Schneider (to Agfa Ansco Corp.). U. S. 2,173,486, Sept. 19. Photographic Ag halide emulsions are sensitized by incorporating in the emulsion a symmetrical or unsymmetrical benzoxazole-trimethinecyanine dye which is substituted in one or both benzene rings of the benzoxazole nuclei and may contain a substituent in the trimethine chain linking the benzoxazole nuclei. Suitable substituents for the benzene rings of the benzoxazole nuclei are: alkyl groups, hydroxy groups, alkoxy groups, halogens and amino groups; the H atoms of the amino groups may be substituted by alkyl groups, acetyl groups, propionyl groups or other org. acid radicals. The substituted dyes used are well suited for the orthochromatic sensitization of photographic Ag halide emulsions. As compared with the unsubstituted benzoxocarbocyanines, they produce a maximum of sensitivity which is displaced toward the long wave region of the spectrum. Furthermore, the aforesaid substituted dyes are distinguished by an increased intensity of sensitization. Numerous examples with details are given.

Photographic diazotype layers. S. C. & P. Harding Ltd. and Werner P. Leuch. Brit. 507,153, June 9, 1939. Light-sensitive layers contain diazo compds. derived from amines of the type 1-amino-2,5-dialkoxy-4-*N*-alkyl (or -aralkyl)-acylaminobenzene. In place of alkoxy groups, β-alkoxy-alkyl ether groups may be used. Suitable acyl groups are Bz, Ac, carboalkoxy, *p*-toluenesulfonyl and substituted Ac groups such as alkoxyacetyl or phenoxyacetyl groups. Among examples, the $ZnCl_2$ double salts of (1) 4-diazo-1-*N*-ethylbenzoylamino-2,5-diethoxybenzene and (2) 4-diazo-1-*N*-butylacetylamino-2,5-dipropoxybenzene are used. Paper so sensitized may be developed with a soln. of phloroglucinol, BzONa, HCOONa, tartaric acid and saponin. In the case of papers to be developed by NH_3 gas, slow-coupling azo components such as R-salt and Schaeffer-salt are included in the layer.

The compds. are prepd. by converting an aminohydroquinone dialkyl ether into the monoalkylamine by treatment with an alkyl ester of *p*-toluenesulfonic acid, acylation of the amino group, mononitration of the product, reduction of the NO_2 group with Fe and HCl or AcOH, and diazotization of the resulting amine.

Developing images on a diazo layer with use of steam. Roelof J. H. Alink and Johannes Aninga (to N.-V. Philips' Gloeilampenfabrieken). U. S. 2,172,783, Sept. 12. Various details of app. and operation.

Photographic fixing salts. Kodak A.-G. Ger. 677,381, June 26, 1939 (Cl. 57*b*. 13.04). Addn. to 638,735 (*C. A.* **31**, 2952[9]). A fixing salt (thiosulfate) compn. resistant to decompn. by acids is made by dry-mixing a solid acid with a fixing salt and adding alkali sulfite or sulfonate, together with NH_3, borax or amines. Thus, the mixt. may contain $(NH_4)_2S_2O_3$, anhyd. $Na_2S_2O_3$, borax and boric acid.

Photographic film. Martin Marsco (to Du Pont Film Mfg. Corp.). U. S. 2,172,801, Sept. 12. A transparent support such as one of a nitrocellulose compn. carries a light-sensitive layer, and an intermediate layer of a synthetic resin formed by the action of an aldehyde such as CH_2O on a hydrolyzed polyvinyl acetate to which has been added a soln. contg. benzene 20–40, BuOH 5–15 and Bu lactate 15%, etc.

Motion-picture film with printed marginal indicia such as footage numbers. John H. Clewell and Frank H. McCormick (to Du Pont Film Mfg. Corp.). U. S. 2,173,505, Sept. 19. A roll of film is made which comprises a film base having on one side nonsmearing, permanently indelible, ink-printed marginal indicia, with the other side supporting an unexposed light-sensitive Ag halide emulsion unfogged and unimpaired by its close assocn. with such indicia, and provided with marginal perforations spaced from the indicia and undistorted by the application of the ink used.

Photographic printing paper. I. G. Farbenindustrie A.-G. Brit. 507,168, June 12, 1939. A metal soap of a sulfonated castor oil that is insol. in the treatment baths to be used is incorporated in 1 or more layers of the paper. Suitable salts are the Al, Ba, Ca and Mg salts. The soaps may be added to the emulsion, to the baryta loading, to a backing, adhesive or protective layer, or to the paper pulp. In an example, methylcellulose (I) in aq. soln. is mixed with sulfonated castor oil and a mixt. of I and Al_2O_3 in aq. AcOH soln. is added, the resulting dispersion being mixed with the photographic emulsion.

Protective layers on photographic pictures. Adolf Jung (to Agfa Ansco Corp.). U. S. 2,173,480, Sept. 19. A photographic material having a gelatin emulsion layer contg. a developed, fixed and washed picture, such as one on a support of film material, is provided with a protective layer by applying to it, while still moist, an aq. dispersion of a highly polymeric compd., such as polyacrylic acid methyl ester, adapted to form a uniform film with a hard surface of natural or artificial org. colloidal character, and drying the coating layer.

6—INORGANIC CHEMISTRY

W. C. FERNELIUS AND L. L. QUILL

Polyborates. I. Alkali borates. Adolfo Ferrari and A. Magnani. *Gazz. chim. ital.* **69**, 275–84 (1939).—In spite of numerous investigations, the structure of alkali polyborates is not clear, and different workers have obtained discordant results. In view of this, the following polyborates were prepd. and their constitutions studied. *Metaborates.*—$K_2B_2O_4.3H_2O$, $Rb_2B_2O_4.3H_2O$, $Cs_2B_2O_4.7H_2O$. *Tetraborates.*—$K_2B_4O_7.4H_2O$, $Rb_2B_4O_7.5H_2O$, $Cs_2B_4O_7.5H_2O$, $(NH_4)_2B_4O_7.4H_2O$. *Decaborates.*—$K_2B_{10}O_{16}.8H_2O$, $Rb_2B_{10}O_{16}.7$ or $8H_2O$, $Cs_2B_{10}O_{16}.7H_2O$, $(NH_4)_2B_{10}O_{16}.7$ or $8H_2O$. In prepg. the borates, the procedures described in the literature were followed. Only *Cs tetraborate* and *Cs decaborate* are new. Although the literature describes successful attempts to prep. hexaborates, octaborates and dodecaborates, none of these could be prepd. by F. and M. by following the procedures described. The H_2O contents of the borates were in general higher than the value corresponding to the general formula of thallous borates, $Tl_2B_{2n}O_{3n+1}.nH_2O$, already found by F. and Ciccioli (*C. A.* **32**, 4456[5]) and the compn. of the borates prepd. in the present work corresponded to $M_2B_{2n}O_{3n+1}.(n+2)H_2O$. Although the borates are derived from the acid $H_2B_{2n}O_{3n+1}.nH_2O$, they contain 2 extra H_2O mols. because each of their cations is capable of hydration. The greater tendency to hydrate and the greater electrostatic character of the alkali cations compared with those of Tl cannot be attributed to the smaller sizes of these cations because the radius of the Tl ion is

almost equal to that of Rb and is less than that of Cs, although it should lie within the electronic sphere of Tl. The very large no. of external electrons of Tl acts therefore as a more effective screen than in the case of alkali metals against the pos. charge of the nucleus, to which the attraction of the H_2O mols. to O and hence hydration of the cations is attributable. The anomalies shown by $Cs_2B_2O_4.7H_2O$, $Rb_2B_4O_7.5H_2O$ and $Cs_2B_4O_7.5H_2O$ are discussed. They are difficult to explain, but further light may be thrown on the problem by an x-ray study. **II. Tetraalkylammonium borates.** A. Ferrari and G. Pareti *Ibid.* 284–90.—Since only 1 tetraalkylammonium borate has been described (cf. Milbauer, *C. A.* **7**, 2544) and the H_2O in this does not conform to the formula assigned by F. and Ciccioli to tetraboric acid (cf. *C. A.* **32**, 4456[8]), other borates of this type were prepd. and studied. Attempts to prep. $(NMe_4)_2B_4O_7$ by the method of Milbauer (*loc. cit.*) and also with other proportions of NMe_4OH and H_3BO_3 were unsuccessful, and if this compd. exists it is too sol. to isolate. Similarly a definite compd. could not be isolated from NEt_4OH and H_3BO_3, although in this case a solid product was obtained. Because with increase in the B_2O_3 content of borates of a given base the soly. diminishes, it was found to be possible to prep. decaborates. The following new borates were prepd., in each case by pptn. from a boiling aq. mixt. of H_3BO_3 and the particular alkylammonium base. *Tetramethylammonium decaborate*, $(NMe_4)_2B_{10}O_{16}.nH_2O$; *trimethylethylammonium decaborate*, $(NMe_3Et)_2B_{10}O_{16}.nH_2O$; *dimethyldiethylammonium decaborate*, $(NMe_2Et_2)_2B_{10}O_{16}.nH_2O$; *methyltriethylammonium decaborate*, $(NMeEt_3)_2B_{10}O_{16}.nH_2O$; *tetraethylammonium decaborate*, $(NEt_4)_2B_{10}O_{16}.nH_2O$, where n is 4 or 5. In each case there was doubt whether $4H_2O$ or $5H_2O$ was present. The general formula is therefore either $(NR_xR'_{4-x})_2B_{10}O_{16}.4H_2O$ or $(NR_xR'_{4-x})_2B_{10}O_{16}.5H_2O$. Either formula makes impossible the formula assigned by Menzel to decaboric acid. However, the degree of hydration conforms to the general formula $H_2B_{2n}O_{3n+1}.nH_2O$ attributed by F. to polyboric acids. At 16° satd. aq. solns. of $(NH_4)_2B_{10}O_{16}.nH_2O$, $(NMe_4)_2B_{10}O_{16}.nH_2O$ and $(NEt_4)_2B_{10}O_{16}.nH_2O$ contained 0.1408, 0.1195 and 0.2593 mol., resp., per l. of soln. C. C. Davis

Phosphoryl bromofluorides. Harold S. Booth and Charles G. Seeguiller. *J. Am. Chem. Soc.* **61**, 3120–2 (1939).—The fluorination of phosphoryl tribromide with SbF_3 yields POF_3, POF_2Br and $POFBr_2$. These compds. have been isolated and purified. The b. ps., vapor pressure data, gaseous and liquid ds. of POF_2Br and $POFBr_2$ and some of their chem. properties are described. A. B. Garrett

The polymerization and depolymerization of phosphonitrile chloride. O. Schmitz. *Z. Elektrochem.* **45**, 651 (1939). Phosphonitrile chloride, $NPCl_2$, is one of the few inorg. compds. for which a series of polymers exists. The lowest member of the series is triphosphonitrile chloride, which, when heated above 250°, as is the case with the other polymers, yields a rubber-like polymer of high mol. wt. Although the structure of the latter is established the polymerization process has been studied very little. S. reports the related exptl. work dealing with equil. relations. On heating 1 g. of the trimer in a sealed 100-cc. quartz tube at 600° polymerization occurs in a homogeneous gas phase without the formation of the rubber-like polymer of high mol. wt. The reaction mixt. contains appreciable quantities of a tetramer besides higher polymeric cryst. and liquid forms and also unchanged trimer. Systems of similar compn. are obtained when the tetramer or the rubber-like polymer is subjected to the same exptl. conditions. Thus a true equil. is believed to exist. If true equil. exists between the individual polymers, an increase in concn. or an increased pressure must cause an increase in the quantity of higher polymer formed in the system. This is established by exptl. work. Increase of temp. for certain compns. of the mixt. favors the formation of the rubber-like form. With increasing temp., the quantity of the higher polymeric form existing in equil. decreases. Accordingly polymerization is an exothermal process. From the above it follows that the rubber-like polymer must depolymerize completely. This is accomplished by heating *in vacuo* at 380°. Heating phosphonitrile chloride to higher temps. induces irreversible reactions of a secondary type in which traces of a nitrilophosphonitrile chloride and an inelastic polymer of high mol. wt. were observed. W. A. Cook

The reaction of gallium and perchloric acid and the preparation and properties of gallium perchlorate hydrates. Laurence S. Foster. *J. Am. Chem. Soc.* **61**, 3122–4 (1939).—Ga dissolves rapidly in hot concd. $HClO_4$ and in $KClO_4$-H_2SO_4 mixts. Prepn. and properties of $Ga(ClO_4)_3.6H_2O$ and $Ga(ClO_4)_3.9.5H_2O$ are described. A. B. Garrett

The periodates of copper. R. K. Bahl and Surjit Singh. *J. Indian Chem. Soc.* **16**, 269–72 (1939).—Quaternary Cu paraperiodate (Cu_2HIO_6) was obtained as a yellowish green cryst. powder by drying at 45° the ppt. formed from (1) treating an aq. suspension of Cu carbonate with paraperiodic acid or (2) boiling an aq. suspension of $Na_2H_3IO_6$ with excess of $CuSO_4$ soln.; it is stable at 120° (in air) or at 110° (*in vacuo*). Deep-green Cu paraperiodate heptahydrate $[Cu_5(IO_6)_2.7H_2O]$ was formed by drying at 45° the ppt. formed by the addn. of paraperiodic acid to dil. Cu acetate soln.; at 74° (65° *in vacuo*) water was slowly lost with formation of the pentahydrate. The vapor pressures of the heptahydrate and pentahydrate at 74° were 5 and 3 mm., resp. George Ayers

The aquation of carbonato pentammine cobaltic bromide. Arthur B. Lamb and Roger G. Stevens. *J. Am. Chem. Soc.* **61**, 3229 33(1939).—Conductance data indicate that carbonato pentammine bromide, $[Co(NH_3)_5CO_3]Br_3$, undergoes a slow aquation to give an equil. mixture of bicarbonato, $[Co(NH_3)_5HCO_3]Br_2$, aquo, $[Co(NH_3)_5H_2O]Br_3$ and hydroxo pentammine bromides, $[Co(NH_3)_5OH]Br_2$. Bicarbonato pentammine salts undergo a much more rapid aquation. The velocity consts. were computed for these aquation and anation reactions. The mechanism of these reactions is discussed. A. B. Garrett

The stereochemistry of complex inorganic compounds. V. The reaction of carbonates with dichlorodipropylenediamine cobaltic chloride. A new method of determining relative configurations. John C. Bailar and J. P. McReynolds. *J. Am. Chem. Soc.* **61**, 3199–3203 (1939); cf. *C. A.* **33**, 8135[6].—Two diastereoisomeric forms of carbonato di-*l*-propylenediamine cobaltic carbonate were prepd. by a Walden inversion method. A comparison of rotatory dispersion curves for these compds. and analogous compds. in the diethylenediamine series made it possible to det. which of the 2 carbonato forms is obtained. A mechanism for the production of the 2 forms of the carbonato complex has been advanced. The noninverted form is produced through the preliminary displacement of the chloride ions in the *cis*-dichloro-di-*l*-propylenediamine cobaltic chloride by water mols., followed by the displacement of the water mols. by carbonato groups. The inverted form is produced by direct substitution of the carbonato group for the chloride ions within the complex. It was found possible by varying the reaction conditions on the basis of this mechanism to produce either form with either Ag carbonate alone or K carbonate alone. Further it was found possible to produce the inverted form of carbonato diethylenediamine cobaltic carbonate with K carbonate for the first time. A. B. Garrett

Cis-trans interconversion among coördination compounds. I. Investigation of the isomeric dichlorobisethylenediaminocobaltic chlorides by means of a radioactive isotope of chlorine. G. W. Ettle and C. H. Johnson. *J. Chem. Soc.* **1939**, 1490–6.—The mechanism of the interconversion of green 1.6$[Coen_2Cl_2]Cl$ (I) and violet 1:2-$[Coen_2Cl_2]Cl$ (II) was studied by means of the redistribution of Cl ions in the presence of radioactive Cl obtained by mixing $RaCl_2$ and powd. $Be(_{17}Cl^{35} + {}_0n^1 \rightarrow {}_{17}Cl^{36})$. Intramol. rearrangement is improbable. In hot H_2O, the Cl in the coördination sphere is replaced by H_2O, and the

isomers are then obtained after evapn. The relative amts of the isomers appear to be controlled largely by the soly. The *cis*-chloride (II) is less sol. than the *trans*-(I); this accounts for the I → II conversion in hot H_2O. The *trans*-chloride forms a sparingly sol. addn. compd. with HCl; this explains the action of HCl in the II → I conversion.
Wm. E. Trout, Jr.

Color in relation to chem. constitution of inorg. salts of isonitrosopyrazolones and isoxazolones (Dutt, Dass) 10.

7—ANALYTICAL CHEMISTRY

W. T. HALL

Titration with polarometric indication of the end point. A. Neuberger. *Arch. Eisenhüttenw.* **13**, 171-4(1939); cf. *C. A.* **33**, 3715⁸.—In many cases it is not necessary to resort to the lengthy polarographic analysis which accomplishes the detn. of different ions in a soln. one after another by applying a gradually increasing voltage to the soln. and photographing (or recording) the satn. currents. If only one single ion is to be detd. polarographically it is sufficient to start with a certain voltage across the cell and add the titration agent; the deflection of the galvanometer decreases and as soon as this remains const. the end of the titration is reached. The simple visual observation, no recording, of the current in the galvanometer gives an accurate indication in short time. A practical example of the titration of Cu with salicyl aldoxime in a sample of steel is described in detail. Ten references. M. Hartenheim

Rapid method for the volumetric titration of copper in bronze, etc. Ursula F. Willis. *Analyst* **64**, 816-17 (1939). Dissolve 1 g. of the sample in 10 ml. of a mixt. prepd. from 250 ml. concd. HCl and 50 ml. of concd. HNO_3. Heat gently until the dense brown fumes have evapd. Cool, add 40 ml. of cold water and 7 g. of urea. To the cold soln. add 5 g. of KI and titrate with $Na_2S_2O_3$ soln. which contains 40 g. of the crystd. salt and 1 g. Na_2CO_3 per l. The thiosulfate should be standardized against Cu in the same way. W. T. H.

Rapid method for iron in open hearth slags. Chas. H. Cramer. *Chemist Analyst* **28**, 59(1939).—The usual method of titrating Fe with $KMnO_4$ in the presence of HCl is described; the novelty consists in first treating 0.3 g. of the sample with 2 ml. of water, 5 ml. of 70% $HClO_4$ and 3 ml. of HF. After fuming 2 min. the usual procedure is followed. W. T. H.

Silicosis and the analyst. F. S. Fowweather. *Analyst* **64**, 779-87(1939).—The various aspects of this disease are considered and it is shown that, as a rule, the chemist can give very little help to the physician and radiologist. Occasionally, however, an abnormally high SiO_2 content of the lungs may give a clue to the existence of the disease although the lungs may not show any fibrosis. Directions are given for ashing lungs and detg. the SiO_2 content along orthodox lines. W. T. H.

Determination of manganese by means of 8-hydroxyquinoline in presence of magnesium. G. Stanley Smith. *Analyst* **64**, 787-94(1939).—According to Gotô, *C. A.* **32**, 2863⁴, oxine ppts. Mn completely at pH 5.87-10.0 but Mg is not pptd. below pH 7. It should, therefore, be possible to ppt. Mn in the presence of Mg with oxine. The method which S. proposed for detg. Al, *C. A.* **33**, 8519⁸, was applied to the detn. of Mn. As a result of considerable experimentation, the conclusion is drawn that 5-30 mg. of Mn can be sepd. by a single pptn. with oxine provided only 10 mg. of Mg is present, but with larger quantities of Mg (0.1-0.5 g.) a double pptn. is necessary. W. T. H.

Detection of germanium in ores and industrial wastes. S. A. Borovik and S. K. Kalinin. *Soviet Geol.* **9**, Nos. 4-5, 140-1(1939).—Spectral data are given for ores and residues from Zn, Cd, Pb and Cu smelters from various parts of the U. S. S. R. F. H. Rathmann

Centrifugal-volumetric determination of metals as oxinates. Yasumitu Uzumasa and Isao Kayama. *J. Chem. Soc. Japan* **60**, 839-44(1939).—A simple, though not very accurate method for detg. Ni, Co, Zn, Mn and W consists in forming a ppt. with 8-hydroxyquinoline and measuring the vol. of ppt. in a graduated centrifuge tube.
T. Katsurai

Composition of lithium and potassium salts precipitated by the uranyl acetate reagents for sodium. Earle R. Caley and W. O. Baker. *Ind. Eng. Chem., Anal. Ed.* **11**, 604-7(1939).—Triple acetates, analagous to those of Na, are formed by Li in the presence of uranyl acetate and Mg, Co, Ni, Fe(ous) and Mn. No ppts. were obtained with Cd, Hg and Cu. Sensitivity studies of these reagents with Na and Li indicate that the triple acetate formed with Cu should be the most satisfactory qual. reagent for Na since the other more sensitive reagents are also sensitive to Li. From concd. K solns. $KUO_2(OAc)_3$ is pptd. by all uranyl acetate reagents for Na. H. A. Frediani

The hypochlorites of calcium of high titer and their preservation. A. Guillaume and Y. Nicolas. *Ann. chim. anal. chim. appl.* **21**, 261-6(1939).—In France, bleaching powder is evaluated in terms of Gay-Lussac degrees which represent the l. of Cl_2 which can be obtained from 2 kg. of the powder. Four large French supply houses furnish "chloride of lime" equiv. to 220° under the names, *Jav, Chlorfix, Perchlorfix* and *Perfix*. In Nov., 1938 expts. were started which were meant to cover 1 yr. but were terminated in July because of the impending war. These expts. show that bleaching powder of 220° has excellent keeping qualities in an unlighted ice chest and is much more stable under all conditions than are ordinary samples of bleaching powder. Three methods of iodometric titration were employed in the tests: (1) treatment with KI and AcOH followed by titration with $Na_2S_2O_3$ soln., (2) treatment with HCl in place of the AcOH and (3) substitution of $KHCO_3$ for the acid. The Pontius method, which uses $NaHCO_3$, gives somewhat higher values than are obtained when HCl is used and the results are a little higher with HCl than with AcOH, but the difference rarely exceeds a few Gay-Lussac degrees. Diln. with $CaCO_3$, Na_2CO_3 and $NaHCO_3$ caused more rapid deterioration of the product in the order named. Diln. with sand or talc had no effect upon the keeping qualities. The keeping qualities are excellent when the samples are kept in sandstone or metallic containers and there is much less loss of Cl_2 than with ordinary bleaching powder over a period of several months. W. T. H.

Determination of hydrocyanic acid by the picric acid method and the KWSZ photometer. J. T. Sullivan. *J. Assoc. Official Agr. Chem.* **22**, 781-4(1939). A procedure (technique described in detail) is proposed for the detn. of small quantities of HCN in individual white clover plants. It consists essentially in autolyzing 10 g. of fresh clover leaves in a 500-cc. short-necked Kjeldahl flask by allowing to stand several days at room temp. with 5 cc. C_7H_8, steam-distg. 80-90 cc. into 5 cc. of 2% KOH, making to 100 cc., adding a 20-cc. (or smaller) aliquot to 10 cc. of aq. alk. picrate soln. (25 g. Na_2CO_3 and 5 g. picric acid per l.), heating in boiling water for exactly 5 min., placing in 1 absorption cell of the KWSZ photometer and placing in the other cell a blank prepd. by heating 10 cc. of the alk. picrate soln. with 20 cc. of H_2O or of 0.1% KOH, balancing the instrument against the blank (with a 10% aq. soln. of $CuSO_4.5H_2O$ as a light filter), reading the transmission of the unknown in the other cell and converting the percentage of transmission into wt. of HCN by means of a curve previously prepd. from standards. The method can measure amts. of 0.01-0.20 mg. HCN. A comparison with the alk. titration method gave results averaging 8% higher by the picrate method. The various steps of the procedure, especially the conditions of autolysis and distn., need further study, particularly if the method is applied to plants other than white clover. A. P.-C.

The catalytic microchemical reaction of Denigès for

detecting hydrocyanic acid and its application to the study of uric acid. Ardoino Martini. *Pub. inst. investigaciones microquím., Univ. nacl. litoral* (Rosario, Argentina) 1, 61–4(1937).—If uric acid is oxidized with HNO_3 the alloxan thus produced can be detected by transforming it to an oxaluramide by means of the HCN-catalyzed reaction of Denigès (*C. A.* 21, 2628). The use of various amines instead of NH_3 in the formation of the oxaluramide increases the sensitivity of the reaction; butylamine gives the most sensitive test. Aprox. 1 γ of uric acid can be detected in this way. T. H. Dunkelberger

The microchemistry of the rare earth metals. Ardoino Martini. *Pub. inst. investigaciones microquím., Univ. nacl litoral* (Rosario, Argentina) 1, 71–5(1937).—The behavior of each of the rare earth metals toward Na_2SO_4, K_2SO_4, NH_4 succinate (I), RbCl, CsCl and $K_4Fe(CN)_6$ is redetd. and the sensitivity of each reaction is found. The most sensitive is that with I (about 1 γ of each element). By means of CsCl and RbCl, separately, in concd. H_2SO_4 it is possible to differentiate microscopically between the Ce and Y subgroups. Yt can be differentiated from Er by means of the neg. reaction of the latter with Na_2SO_4; similarly, Th can be distinguished from the rare earths by its neg. reaction with $K_4Fe(CN)_6$. T. H. D.

Microiodometric determination of nitrogen. S. M. Strepkov. *Ann. chim. anal. chim. Appl* 21, 257–60(1939).—To det. 2.5–0.1 mg. of N in org. materials, it is recommended to heat 10–15 min. with concd. H_2SO_4 with occasional addn. of H_2O_2 to oxidize all C compds. and convert the N into NH_4HSO_4. After this treatment, cool and add water to exactly 25 ml. Mix and take 10 ml. aliquots for further analysis. To the aliquot add 3 ml. of 0.1 *N* $KBrO_3$ and 1 ml. of 10% KBr soln. Mix, add 3–3.2 ml. of 5 *N* NaOH, shake well and then add 1 ml. of 10% KI and 3–3.5 ml. of 5 *N* HCl. After 20 min. in the dark, titrate the liberated I_2 with 0.01 *N* $Na_2S_2O_3$. At the same time run a control expt. with the same quantities of reagents. The ml. of $Na_2S_2O_3$ equiv. to the $KBrO_3$ required to oxidize NH_4^+ to N_2 (3 equiv. for each N) is detd. by the difference between the vol. used in the control expt. and that of the analysis. W. T. H.

Colorimetric determination of carbon disulfide. W. Demann and A. Adelsberger. *Gluckauf* 75, 556–60(1939). The CS_2 content of benzene or of motor fuel has usually been detd. by the xanthate method in which the CS_2 reacts with EtOH and KOH and the product with Cu^{++}. Tischler, *C. A.* 26, 1212, proposed a somewhat simpler method which is the same in principle as the patented process of Robinson Bros., Parkes and Mitchell (*C. A.* 31, 8847[1]) for removing small quantities of CS_2 from vapors. The procedure here described is based on the same reaction, but it is more accurate than the xanthate method for detg. small concns. of CS_2. The gas is made to react with a soln. of piperidine in monochlorobenzene whereby pentamethyldithiocarbamic acid is formed. This acid in the presence of Cu^{++} is converted into a brown salt which, at low concns., can be used for the colorimetric detn. of CS_2. The method is suitable for detg. 0.01–0.07% CS_2 in benzene after the removal of H_2S and mercaptans by washing with NaOH soln. Thiophenes up to 20% do not interfere. A simple device is described for mixing 1 ml. of benzene with 21.5 ml. of the reagent. L. P. Rockenbach

Detection of barbital in exhumed decaying corpses. E. Weinig. *Deut. Z. ges. gerichtl. Med.* 31, 189–93(1939).—W. discusses available methods for detg. barbital in decaying material and recommends a few minor changes in the procedure for obtaining the chloroform ext. Frances Krasnow

Determination of nicotine in fatal poisoning. Knud O. Møller and Margarethe Simensen. *Deut. Z. ges. gerichtl. Med.* 31, 55–9(1939).—Nicotine picrate analysis was found dependable in detg. the cause of death. F. K.

A method for the determination, in the form of ammonia, of amido and nitrile nitrogen. Léon Palfray, Sébastien Sabetay and Santiago Rovira. *Compt. rend.* 209, 483–5(1939).—The N of amides or nitriles can be measured more accurately as NH_3 liberated by hydrolysis than by measuring the amt. of alkali hydroxide consumed in the hydrolysis. Take a sample contg. 0.01 atom of N, boil 1 hr. with 100 cc. BzOH and 10 g. KOH, collect the liberated NH_3, in H_2O, and titrated with 0.1 *N* H_2SO_4 in the presence of methyl orange. Rachel Brown

Determination of ethyl alcohol in the presence of methyl alcohol, isopropyl alcohol and acetone. E. J. Boorman. *Analyst* 64, 791–4(1939).—MeOH, isopropyl alc. and EtOH are often present in solvents and lacquers. They are not removed completely by the Thorpe and Holmes method (*J. Chem. Soc.* 83, 314 (1903)) and their presence lowers the d. of the distillates and increases the apparent EtOH content. The prepn. of a distillate contg. the 4 compds. just mentioned is obtained easily by the method of T. and H. It has been shown by Denigès (*C. A.* 4, 1725[1]) and later by Hoskins (*C. A.* 31, 6583[6]) that AcMe forms an insol. compd. with $HgSO_4$. The method here proposed depends upon the formation of an analogous compd. with $HgCr_2O_7$ which will completely ppt. acetone. These Hg compds., however, are sensitive to shock or heat when dry. For this reason the proposed method should only be used when other methods are inconvenient and then only by skilled workers. To the distillate obtained by preliminary purification, which has been dild. if necessary, add 100 ml. of a reagent which has been prepd. by dissolving 100 g. HgO in 250 ml. concd. H_2SO_4 and dilg. to 2 l. with water contg. 135.7 g. of $K_2Cr_2O_7$. After 30 min. in a well-stoppered flask, boil the soln. under reflux for 15–20 min. If AcMe or isopropyl alc. is present a heavy red ppt. is obtained; the isopropyl alc. is oxidized to AcMe during the treatment. Allow the contents of the flask to cool somewhat and obtain 500 ml. of distillate by distg. with steam. The MeOH has been oxidized to CO_2 and the EtOH to AcOH. Finally titrate the AcOH in the distillate with 0.1 *N* NaOH to a phenolphthalein end point. W. T. H.

Bromine number of cinnamic derivatives. A. Lespagnol, R. Herlemont and G. Stern. *J. pharm. chim.* 29, 447–59 (1939); cf. *C. A.* 31, 6820[9]; 33, 9545[1].—In Br titration (cf. Volmar and Samdahl, *C. A.* 22, 2476), $Na_2S_2O_3$ is replaced by aq. SO_2 soln. in removing excess of Br, so as to avoid pptn. of S. (*a*) Tentative sapon. of PhCHBr·CHBrCO$_2$H (*A*), m. 200° by boiling with concd. alc. KOH shows that heating should last at least 8 hrs. (not 5 hrs.) for complete removal of Br_2. Also, a new reaction is found: An alc. soln. of *A* gives with $AgNO_3$ soln. quant. pptn. of 1 mol. of AgBr, with formation of ω-bromostyrolene (PhCH:CHBr) and 2 bromocinnamic acids of steric difference. (*b*) Quant. bromination of PhCH:CHCO$_2$H (*B*) to obtain *A* takes place very slowly (cf. Duquénois, *C. A.* 31, 2185[7]). Dissolve 0.20 g. *B* in 20 cc. Et_2O cooled by a freezing mixt., add 0.8 g. Br (= 3 times in excess) and leave it for 24 hrs. at lab. temp. in diffused light. Remove excess of Br with dil. aq. SO_2 and wash the Et_2O soln. with H_2O (test with $AgNO_3$). Evap. the Et_2O. Warm the residue with 95% alc., bring to 100 cc. and det. Br in an aliquot, after boiling for 10 hrs. with alc. KOH. (*c*) In brominating benzyl cinnamate, and cinnamyl cinnamate, a large excess of Br than with *B* (3–5 times) and 24 hrs.' contact are needed for quant. addn. of Br; removal with alc. KOH is the same as with *B*. The $AgNO_3$ reaction in both cases even after 24 hrs. is far from quant. S. Waldbott

Analytical functional study of nucleic acids. J. A. Sanchez. *J. pharm. chim.* 29, 529–44(1939).—Two colorimetric methods for detg. nucleic acid (*A*) are given. (*a*) By acid hydrolysis of *A*, purine and pyrimidine bases are set free, capable of coupling with the *p*-nitraniline diazo reagent (to 5 cc. of soln. of 0.5 g. *p*-$NH_2C_6H_4NO_2$ in 100 cc. H_2O contg. 0.5 cc. concd. H_2SO_4 add 1 drop of 10% $NaNO_2$). After making alk., a yellow color is formed. The procedure is described in detail. (*b*) Morphine-HCl, a 1% soln. in 50% H_2SO_4, forms with solid *A* a strongly red-violet, stable color, proportional in intensity to the concn. of *A*. From a type soln. of 0.1 g. *A* in 100 cc. of 50% H_2SO_4 a scale of standards from 0.0001 to 0.0005 g. of *A* is made, and compared with 0.2 and 0.5 cc. of solns. of the

unknown in 50% H_2SO_4. (*c*) Modifications of other known reactions of *A* are also given. S. Waldbott

Studies on the microdetermination of glucose, free and conjugated glucuronic acid. I. Determination of free and conjugated glucuronic acid in the presence of glucose in aqueous solutions. Saburo Kakinuma. *J. Pharm. Soc. Japan* **59**, 635-47 (in English, 244-6) (1939).—The colorimetric method of Ogata and Yamanouchi (*C. A.* **23**, 4718; **25**, 1861) for the microdetn. of free and conjugated glucuronic acid in aq. solns. or in urine does not work in presence of glucose. This difficulty, however, can be easily overcome if the glucose present in the sample is decompd. by fermentation with yeast, previous to the application of the colorimetric method. In the preliminary expts. which are described in this paper and which deal only with ingredients in aq. solns., K. dils. the samples so that the glucose concn. becomes 1% or less, adds NaCl to 0.5–1.0%, and decomposes the glucose by fermenting it for 18 hrs. at 28° by means of *Saccharomyces saké* No. 2. After centrifuging off the yeast, the colorimetric method of O. and Y. for the detn. of free and conjugated glucuronic acid is applied. Nao Uyei

Chromium in the soils of Western Samoa and Niue Island [detn. of small amts.] (Farrell, *et al.*) **15**. Effect of HCl concn. on the reduction of molybdate in the Ag reductor (Hiskey, *et al.*) **2**. Reduction by amalgamated Zn (Stone, Hume) **2**. Sulfanilamide derivs. [analytical studies] (Crossley, *et al.*) **10**.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

ARTHUR M. BRANT

Dolomitization of calcareous sediments. A. Rivière. *Compt. rend.* **209**, 691-2 (1939); cf. *C. A.* **34**, 584[4].—Sea water left in contact with $CaCO_3$ loses much more Mg than is deduced from decrease in the "alkaline reserve," especially when the pH is maintained at a high value, e. g., by removal of CO_2. Any action tending to raise the pH, e. g., circulation or disturbance of the sea by wind or tide, or removal of CO_2 by photosynthetic action, increases the effect. This explains the almost total absence of dolomitization in an undisturbed area, its large amt (up to 17%) in some calcareous sands of the Bahamas Islands, in some dead corals, and in some extremely dolomitized (up to 30–40%) reefs in the Dead Sea. C. A. S.

Differential thermal analysis of kaolinite. S. Caillère and S. Hénin. *Compt. rend.* **209**, 684-6 (1939); cf. *C. A.* **28**, 75[9]; **31**, 8448[8].—Expts. are briefly described showing the influence on the differential thermal analysis curves, particularly the portion indicating the exothermal phenomenon at 1000°, of kaolinite from Djebel Debar (Constantine, Algeria) (1) of the size of the particles (greater or less according as the diam. is above or below 2μ), (2) of various ions introduced by base exchange (Ca, K, Fe, the effect decreasing in this order, the phenomenon with Fe being less than in untreated kaolinite), and (3) of the amt. of base fixed and method of fixation (the effect decreases as the amt. fixed increases, but is increased by subsequent dialysis). Interpretations are not discussed. C. A. Silberrad

The influence of stresses on the arrangement of quartz and crystobalite crystallites in chalcedony, quartzine and lussatite. Fritz Laves. *Naturwissenschaften* **27**, 705-7 (1939).—X-ray work showed that the cryst. part of the blue "chalcedonies" of Weitendorf (near Graz) consists of cubic or quasi-cubic cristobalite. This chalcedony has a lower *n* (1.48) than normal, it is pos. in the fiber direction and has been called quartzine (Meixner). Fiber diagrams of the cristobalite showed that it is weakly deformed cubical and the product is optically pos. like tetragonal crystobalite. The Weitendorf chalcedony has the cristobalite fibers perpendicular to its fiber direction and is a parallel to ordinary chalcedony, which has neg. quartz crystals with *c*-axis perpendicular to its fiber direction. The Mallard name of lussatite is recommended for the chalcedony contg. cristobalite; lussatine is recommended for it if the fibers are optically neg. Further work on specimens contg. chalcedony showed that during crystn. the *c* axes always orient themselves in the direction of the stresses. Quartzine with the reverse optical activity is formed when spherulites crystallize in an opal medium such that the spherulites are not compressed but expanded in the crystn. process. The *c* axes then arrange themselves parallel to the fiber direction. B. J. C. v. d. H.

Chemical and mineralogical study of a new titanium mineral from Nellore District. N. Jayaraman and K. R. Krishnaswami. *Quart. J. Geol., Mining Met. Soc. India* **10**, 97-108 (1938).—Black, opaque, magnetic grains occur as inclusions in garnet. In reflected light they are steel-gray, tinged with pale violet. Chem. analysis gave SiO_2 0.12, TiO_2 65.90, FeO 18.88, Fe_2O_3 15.27 and total 100.17. The results from chem. and phys. investigations show the presence of ilmenite ($FeTiO_3$) and magnetite (Fe_3O_4) mols. with a high content of TiO_2 probably in solid soln., indicating a possible wide range of miscibility between the mols. $FeTiO_3$, Fe_3O_4 and TiO_2. J. F. Schairer

Caledonian tectonics and metamorphism in Skye. E. B. Bailey. *Bull. Geol. Survey, Gt. Brit.* **2**, 46-62 (1939).—The MnO content of the garnets in the Moine rocks near Tarskavaig (Skye) is about 4.2%, and n = 1.80. The relations between the compn. of this garnet and the biotite of the contg. rock and the grade of metamorphism are discussed with references to similar occurrences elsewhere. Cf. Elliot, *et al.*, *C. A.* **32**, 2056[4]. C. A. Silberrad

Discovery of analogs to carnotite sands in northern Fergana. V. I. Popov. *Soviet Geol.* **9**, Nos. 4-5, 32-9 (1939).—The geochem. nature of these sands is very similar to that of the Mesozoic carnotite sands of Colorado and Utah. F. H. Rathmann

Magnetic survey of hematite ore in south Cumberland and Furness. A. F. Hallimond and J. T. Whetton. *Bull. Geol. Survey, Gt. Brit.* **2**, 1-17 (1939).—A magnetic survey of a hematiferous area near Millom (Cumberland), in which the position of the hematite deposits was fairly known through their being worked, showed that the ore is appreciably magnetic, and that it should be possible to detect in this way a vein 10 ft. wide under 60 ft. of cover, but caution is necessary as the magnetic values observed are much less than those due to many dike rocks, being comparable to those due to large boulders in boulder clay or magnetic country rocks. C. A. Silberrad

Cupriferous chalk deposits of Kugitang. V. S. Domarev *Tsvetnye Metal.* **1939**, No. 1, 5-16.—Geol. occurrence and genesis of cupriferous deposits of Kugitang, South-West Turkomania, Russia, are described. Mineralized gypsum lenses are embedded in formations of argillite. The minerals are chalcocite in the sulfide zone, and, probably, malachite and atacamite in the oxidized zones. The Cu contents of the deposits, as far as the preliminary exploration indicates, is too low to justify com. exploitation at the present. B. N. Daniloff

Deposits of copper at Outokompu, Finland and its treatment. Achille Mestre. *Génie civil* **112**, 417-18 (1938).—Ann Nicholson Hird

Copper-bismuth deposits of Adrasman. E. M. Yanishevskiĭ and M. I. Kharitonov. *Soviet Geol.* **9**, Nos. 4-5, 78-94 (1939).—Chalcopyrite is assocd. with quartz, pyrite, hematite, bismutite and emplectite ($CuBiS_2$). F. H. Rathmann

Copper-containing magnetite deposits of the Urals and their exploitation. V. A. Glazkovskiĭ. *Soviet Geol.* **9**, No. 6, 96-101 (1939).—The deposits contain 59% Fe; Cu can be obtained as a by-product. F. H. R.

Nickel and cobalt content of the manganese ores of the U. S. S. R. I. I. Ginsburg. *Soviet Geol.* **9**, Nos. 4-5,

60–77(1939).—Ni and Co enrichment is found in continental Mn and Mn-Fe ores (weathered serpentinites) but not in deposits of marine origin. F. H. R.

Nickel oxide deposits in the Urals. Basile Bogitch. *Compt. rend.* **209**, 652–3(1939).—The chief deposit occurs near Orsk in the southern Urals. It extends horizontally, some 4–20 m. thick, over several 100 km. at a moderate depth below a stratum, rich in Fe_2O_3, 1–4 m. thick. The ore as worked contains about 2% Ni present mainly as garnierite, and has resulted from concn. by atm. action from underlying serpentine, which in the unaltered state contains 0.01 to 0.1% Ni. The total Ni available is estd. at 300,000 tons. Less important deposits occur in the middle Urals within 100 km. of Sverdlovsk. The ore, likewise derived from serpentine, encloses a large mass of marble, which has greatly affected the decompn. of the serpentine, the Ni content varying from 10 to 15% in immediate contact therewith to 1–1.5% at a few m. distance. The ore as worked averages 2–3% Ni, and the amt. available is estd. at 100,000 tons. C. A. S. 2

Ore deposits of southeast Bulgaria. Walther E. Petrascheck. *Metall u. Erz* **36**, 481–4(1939).—A description of the geology of chrome serpentine and Pb-Zn deposits of Bulgaria. H. Stoertz 3

Molybdenum in ores of Kazakhstan (Russia). I. P. Novokhatskii and S. K. Kalinin. *Tsvetnye Metal.* **1939**, No. 4–5, 46–9.—Mo occurs widely distributed as admixt. in various ores of Kazakhstan, particularly in assocn. with Pb ores. The presence of Mo in some of the Cu ore deposits points to its origin from granodiorite-monzonite magmas. In some localities the concns. of wulfenite are of com. interest. B. N. Daniloff 4

Tungsten-molybdenum ore deposits at Lyangar (Russia). I. I. Surnin. *Tsvetnye Metal.* **1939**, No. 4–5, 50–2.—A description of occurrence and mineralogy of W and Mo ores in the Lyangar deposits, Uzbek Republic, Russia. Minerals observed were scheelite, molybdenite and others. No estimate of com. possibilities is given. B. N. D. 5

Coal deposits of the Eastern Urals. V. S. Shekhunov. *Soviet Geol.* **9**, No. 6, 18–30(1939). **New coal deposits in Kirgizia (Fergana).** N. V. Shabarov. *Ibid.* 31–47. **X-ray studies of coal.** I. D. Seletskii. *Ibid.* 48–63.—X-ray data are given for various bituminous and anthracite coals, graphite, humic acids and lignin. **Report on coal and shale deposits. Dublikanskii coals.** A. K. Matveev. *Ibid.* 114–15. F. H. Rathmann 6

Oil occurrences in southwest Lancashire. T. Wolverson Cope. *Bull. Geol. Survey, Gt. Brit.* **2**, 18–25(1939).—Investigation of the oil seepage near Formby (Lancashire) with a peat auger put down 16 ft. showed alternate strata of peat and silty clay both contg. oil, examn. of which gave d. 0.885, initial b. p. 205°, and amts. distg. to 225°, 250°, 275°, 300° and 325°, resp., 1.5, 7, 15, 23.5 and 33.5%; cracking began at 350°. The low sapon. value (1.2 mg. KOH/g.) indicates a probable mineral origin from a deep source, possibly from Carboniferous beds below the underlying Trias. This is rendered more probable by the fact that examn. of the algae of the peat showed that though some are oil-producing, the quantity of such is insufficient to account for the oil found. C. A. S. 1

Perspectives for oil deposits in Turkmenia and Western Uzbekistan. M. I. Varentsov and P. G. Suvorov. *Soviet Geol.* **9**, No. 6, 64–91(1939).—The gases contain 90–98% CH_4 and 0.3 to 0.8% noble gases. Data are given on oil, bitumen and S content. **Combustible shales of the Far East.** A. Z. Lazarev. *Ibid.* 116–18. F. H. Rathmann 2

Heavy mineral assemblages of the Burma oilfields. S. Krishnaswamy. *Quart. J. Geol., Mining Met. Soc. India* **10**, 109–21(1938).—The source rocks of the sediments of the Burma oilfields were cryst. schists and related metamorphic rocks as indicated by heavy mineral assemblages described. J. F. Schairer 3

Petrology of the Permian rocks of the vale of Eden. Henry C. Versey. *Quart. J. Geol. Soc. London* **95**, 275–98 (1939).—The relative amts. of the heavy minerals in these beds (including zircon, rutile, garnet, anatase, staurolite, barite and a little fluorite, sphene aplite and cassiterite) were detd., and their source is discussed. The origin of the red coloration (due to Fe_2O_3), especially of the Penrith sandstone, is discussed, as also the nature and origin of the cementation. C. A. Silberrad 4

Economic geology of Panchet Hill. B. C. Roy. *Quart. J. Geol., Mining Met. Soc. India* **10**, 209–14(1938).—Three analyses of dolomitic limestones are given. Red ocher, fireclay, ironstone, graphite, building stones and road materials are also found in the area. J. F. S. 5

Geology of Jamkhandi (Deccan). Y. T. Apte. *Quart. J. Geol., Mining Met. Soc. India* **10**, 123–33(1938).—Petrographic descriptions of granite gneiss, hornblende-schist, dolerites, traps and some sedimentary rocks are given. J. F. Schairer

Geology of Vengurla Peta. B. G. Deshpande. *Quart. J. Geol., Mining Met. Soc. India* **10**, 167–78(1938).—Two analyses of the Vengurla granite-gneiss are included. J. F. Schairer 6

Report of the imperial agricultural chemist [on soils] (Nath) **15**. Radioactivity of K as a means for detn. of the relative ages of elements in meteorites (Suess) **3**.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Use of activated charcoal in hydrometallurgy and in flotation. S. M. Yasukevich. *Tsvetnye Metal.* **1939**, No. 6, 54–69.—Y. describes the results of his investigation of methods of prepn. of activated charcoal and its use in hydrometallurgy and in flotation. Various gases were tried for the activation of raw birch, pine and spruce charcoals. The best results were obtained by treatment of birch or pine charcoal in a CO_2 atm. in a rotating muffle furnace for 4 hrs. at 800°. Methylene blue was used for the detn. of adsorptive power of the product. The yield of activated charcoal increased from 50% to obtain the specific surface of 180 sq. m. per g. of charcoal, to 87% to obtain the specific surface of 5 sq. meters per g. The following applications of activated charcoal were investigated: (1) Adsorption of Au and Ag from solns. One hundred % extn. of Au and Ag was obtained in lab. from cyanide solns. of low concns. with large amts. of charcoal. With agitation, 150 mg. charcoal of 142 sq. m. surface per g. is required per g. of Au to effect a practically complete extn. of Au from solns. contg. 0.2–16 mg. Au per l. Best results were obtained at temps. of +5 to +20°. Further expts. showed that still better results can be obtained in the extn. of Au from chloride solns. and Ag from nitrate solns. Charcoal pulverized to 100- to 200-mesh was found to be most effective, and also convenient for flotation. When percolation of solns. is employed, 20-mesh is recommended. The above tests were made in the lab. with pure solns., but tests made on actual flotation mill materials confirmed the above results. (2) Flotation. A study of flotability of activated charcoal showed that the more adsorbent the charcoal the more difficult it is to float. Of the various reagents tested, kerosene, pine tar and shale oil were found satisfactory. From 90 to 95% extn. was obtained with charcoals of lower specific surfaces (5 to 12 sq. m./g.), the consumption of the reagents varying from 160 to 180 kg./ton of Au-carrying charcoal. Extn. decreases with increasing liquid/solid ratio, but the purity of the concentrate increases. Neutral or acid flotation pulp produces the best results. (3) Treatment of Au-charcoal concentrates. After various methods of recovering Au were tried, the following method was selected as the most satisfactory: The Au charcoal concentrate is mixed with water (50%) and pressed into briquets at 70–75 atm. pressure. The briquets are then 8 9

ignited in iron burners in air. The product is then melted into Doré metal. (4) Purification of industrial waters. Activated charcoal is useful for purification of circulating flotation water, and for removal of excess oil. The treatment increases the output in flotation of Cu and Zn ores.
B. N. Daniloff

Extraction of minerals by means of selective grinding. F. N. Belash, V. I. Saltanov and E. V. Vinokurova. *Tsvetnye Metal.* **1939**, No. 1, 55–6.—With a view of improving the sepn. of molybdite by flotation the authors propose a selective method of grinding molybdite ores, which takes advantage of the low hardness of molybdite, 1 to 2 on Mohs' scale, as compared to 6 to 7 of the gang minerals, quartz and feldspar. The grinding was done in a rod mill with pulp d. of 50% and the weight of rods 2.4% of the weight of ore. The rods were covered with rubber sheaths. It was found that the gang was not ground appreciably whereas a considerable proportion of molybdite passed through 325-mesh. The enrichment ratio of 5.8 to 6.45 was obtained with the extn. of 84–85%. This method was also tried on urano-radium sulfidic ores whereby 65% of the mineral was sepd. into −325 class.

Present milling practice on Kirkland Lake [gold] ores. Harry Hanson. *Can. Mining J.* **60**, 596–9(1939).
W. H. Boynton

Milling lead-zinc-gold ores in Marinduque. Lee E. Blinzler. *Eng. Mining J.* **140**, 51–3(Nov., 1939).—The project of Mineral Resources, Inc. on Marinduque in the Philippines yields a concentrate of low metal content which necessitates close control of operation. Mine capacity is 150 tons, turning out Pb and Zn concentrates and a Au bullion. The flow sheet is shown.
W. H. Boynton

Howe Sound's new Holden mill H. A. Pearce and V. A. Zanadvoroff. *Eng. Mining J.* **140**, 31–4, 35(Nov., 1939).—The Holden orebody is primarily a Cu deposit, but contains important Au as well as minor Ag values The capacity of the recently enlarged concentrator now exceeds 2000 tons per day. The use of deep matless air-lift cells is a feature of the flotation section. Flowsheets are shown.
W. H. Boynton

Flash-roasting and losses in cyanidation of calcined concentrate. H. C. Baghurst and H. W. Gartwell *Chem. Eng. Mining Rev.* **32**, 13–14(1939).—Hard spherical grains found on calcining Kalgoorlie flotation concentrates are presumably caused by unintentional flash-roasting. Support is given to the suggestion that these grains might be a source of loss by being impenetrable to cyanide solns.
W. H. Boynton

Treatment of Kalgoorlie ore. Straight cyanidation. R. C. Buckett. *Chem. Eng. Mining Rev.* **31**, 489–90 (1939).—Straight cyanidation is claimed to have the following advantages over the precyanidation process: (1) in a new mill, it is cheaper in first cost; (2) on straight sulfide ore as treated by Lake Shore and Star, Ltd. the flotation process as outlined yields tailing carrying negligible amts. of sulfide and no free Au particles. Exptl. tests of straight flotation followed by cyaniding the tailing and also precyaniding followed by flotation gave identical results. **Precyanidation process.** J. Cornelius. *Ibid.* 490.—Factors favoring this process are: (1) higher recovery, (2) less locking up of Au in the grinding circuit and concentrate and calcine circuits and (3) incomplete flotation of pyrite does not mean higher tails. Disadvantages are: (1) loss of sol. Au in the flotation tailings, (2) more difficult flotation and higher reagent costs and (3) higher constructional costs. **Great Boulder experiences.** J. R. Hylton. *Ibid.* 490–1.—The 2 outstanding factors that play the most important part in effecting recoveries are widely divergent head values and the differential actions of different types of ore in the flotation circuit. Temp. control in the roasting section avoiding temps. in excess of 600° is necessary for good Au recovery. At Great Boulder the gain by precyanidation has been approx. 8 shillings per ton with the extra recovery offsetting the extra cost of treatment.
W. H. Boynton

Noamundi Iron Mine. F. G. Percival *Trans. Mining Geol. Met. Inst. India* **35**, 143–52(1939).—A very complete chem. analysis of the hematite ore is given. 250 million tons of ore of average Fe content over 60% are available.
J. F. Schairer

Autoclave process of extraction of tungsten from concentrates. I. N. Maslenitskiĭ. *Tsvetnye Metal.* **1939**, No. 4–5, 140–3.—M. conducted lab. and semicom. tests with the purpose of developing a chem. process of extn. of W from scheelite concentrates contg. about 10% WO_3 by the use of autoclaves. Preliminary tests were made with mixts. of scheelite ground to −200 mesh, and Na_2CO_3. It was found that at 200° and 15 atm. pressure the ratio $Na_2CO_3 . WO_3 = 3$ should be used to effect an almost complete (98%) decompn. of scheelite according to the formula $CaWO_4 + Na_2CO_3 \rightleftarrows Na_2WO_4 + CaCO_3$. Further tests showed that ore concentrates with various concns. of scheelite require greater amts. of Na_2CO_3 than pure scheelite mixts.; for 90% decompn. of $CaWO_4$ the ratio should be from 3 to 4.5 the poorer the concentrates. On semicom. scale 85% decompn. of $CaWO_4$ was obtained. Extn. of W from solns. gave ppts. contg. 50–63% WO_3. The work is being continued to establish the technique of the autoclave process on com. scale.
B. N. Daniloff

Neutralization of injurious effects of oxygen and carbon dioxide in the flotation of copper-zinc ores. V. A. Malinovskiĭ. *Tsvetnye Metal.* **1939**, No. 1, 44–50.—In earlier reports (*C. A.* **33**, 9221[8]) it was stated that CO_2 decomps. Cu cyanide ions to form Cu^{++} ions; these deposit on the surface of Zn blende and activate it, and thus raise the Zn content of the Cu concentrate. M. developed a new group of reagents (catalytic adsorbers) for neutralization of the injurious effects of Cu^{++} ions. These reagents are colloidal sulfides of Fe, Zn, Pb and Ni. They were prepd. by mixing the sulfides of these metals with Na sulfide. Colloidal sulfides were introduced into a soln. of $CuSO_4$. Results of numerous expts. showed that ZnS is the most efficient deactivating reagent; it improves selectivity and does not decrease the extn. of Cu into the Cu concentrate. Analyses of filtrates showed 0.01 to 0.015 g. Cu per l.; without the addn. the Cu content was 0.20 to 0.30 g. per l. The action of these colloidal sulfides is due to the adsorption of Cu^{++} ions on their surface. Sponge iron is also used for pptg. Cu^{++} ions, but the colloidal sulfide reagents are superior to it. These results were corroborated by tests on com. scale, and the method has been adopted in some of the flotation mills. It is claimed that the extn. of Zn was increased from 61 to 72% and that of Cu from 81 to 86%.
B. N. D.

Features of the Zinc Corporation's new mill. M. A. Mawby. *Chem. Eng. Mining Rev.* **32**, 27–8(1939).—A brief description of the new mill of Zinc Corporation Ltd. at Broken Hill, N. S. W. Capacity is 10,000 tons weekly. Pb, Ag and Zn are recovered by flotation methods.
W. H. Boynton

Agglomeration of pyrite dross. V. Bezhanishvili. *Novosti Tekhniki* **1939**, No. 13–14, 30.—Pyrite dross contg. Fe 52.56, SiO_2 12.20, Cu 0.81, Mn 0.25, P 0.39, S 4.02 and moisture 10.2% was agglomerated with Krivorog ore in the following proportions: 25:75, 40:60 and 60:40. The second type of charge gave the largest yield of agglomerate. The charge was 200 mm. thick and it contained 4% C and 7.5% moisture. The output was higher and the fuel consumption and use of gas for ignition were lower than in the agglomeration of the ore without the dross. The 1.20% S in the charge was reduced to 0.08% in the agglomerate. The Fe content in the agglomerates obtained with the above 3 charges was 61.3, 61.0 and 60.5%, resp.

G. G.

Notes on steel foundry practice. S. Leetch. *Foundry Trade J.* **61**, 182–3, 197–8, 214–16(1939).—A general description of British foundry practice.
I. H.

Serious manganese poisoning among Egyptian manganese miners. E. W. Baader. *Arch. Gewerbepath. Gewerbehyg.* **9**, 477–86(1939).—Mn poisoning caused mental disorders which developed after several years in

men who worked in Mn ore mines when drilling was done by hand. With mech. drilling the mental disorders occurred after 3 weeks to 5 months. Many deaths from pneumonia were noted. Maurice M. Rath

The occurrence of occupational manganese poisoning in the steel industry (apropos of manganese poisoning in a grinder of ferromanganese). H. Voss. *Arch. Gewerbepath. Gewerbehyg.* 9, 453–63(1939).—A ferromanganese grinder after several months developed manganism in which a mask-like face, amyostatic symptoms, disturbances in speech and walk, monocytosis and mild polyglobulism were noted. Considerable improvement occurred in the nervous lesions. Maurice M. Rath

Progressive bulbar paralysis and amyotrophic lateral sclerosis after chronic manganese poisoning. H. Voss. *Arch. Gewerbepath. Gewerbehyg.* 9, 464–70(1939).—Mn caused this condition in a man who worked 15 years with MnO_2. Maurice M. Rath

Metallic materials in the telephone system. Earle E. Schumacher and W. C. Ellis. *Metal Progress* 36, 617–22 (1939).—Qual. chem. compns. and uses of alloys of Pb, Cu, Zn, Ni, Fe, Co, Mo, Cr and Al are given. W. A. M.

Recrystallization of pure aluminum. Masahide Kosaki. *Nippon Kinzoku Gakkai-Si* 3, 349–58(1939).—A new recrystn. diagram of Al was constructed from the measurement of grain sizes of 0–10% worked and annealed Al plates. Grain-growth after recrystn. occurs generally in specimens which were subjected to a large degree of deformation and annealed at high temp. Conclusion: This phenomenon is induced by mutual relation between the difference in potential energy of neighboring crystals and intercryst. diaphram of impurity. H. N.

Some metallurgical features of joining processes for copper and aluminum. F. A. Fox. *Machinery* (London) 54, 681–1(1939).—If Cu plate or sheet is heated with a blowpipe to temp. between 950° and 1050° for a min. or two the oxide globules will segregate to the main boundaries and the strength of the metal will be reduced by as much as 50%. The heating time must be short. The flame is to be neutral. Filler rods contain P as deoxidizer and may contain small quantities of Ni, Ag and V. Hot-hammering is recommended. Al is welded with slight excess of acetylene. H_2 causes embrittlement. If the filler rod is not of the same metal the weld will anodize differently. A 5% Si alloy is widely used. Hammering improves the mech. properties but reduces the corrosion resistance. In bronze welding the use of rods of different analysis from the base metal may lead to local electrolytic corrosion. In the brazing of stainless steel the flow point of the alloy must be above 850°, i. e., above the range where the steel tends to carbide formation. A steel article which has been pickled can only be efficiently brazed (with molten brass) after a period of time has elapsed or after annealing at 700–750°. H_2 must be allowed to escape. If Cu jointed with Sn solder is subject to heat the intermetallic compound layer may grow, and thus affect the strength of the joint. Richard P. Seelig

Properties and methods of manufacture of oxygen-free copper. P. I. Baranov. *Tsvetnye Metal.* 1939, No. 1, 73–83.—A review and discussion of the manuf. and properties of O-free Cu are followed by a description of results of expts. made with the purpose of developing a process of manuf. with the use of Li and Be and by melting under CO_2 atm. Wire bars 5.5 × 5.5 × 55 cm. cast from cathode Cu melted under charcoal and deoxidized with 0.012% Li or Be have high d., good mech. properties and workability. Two-mm. wire drawn from these bars has elec. cond. not lower than that of O-free Cu, but lower ductility. Bars cast from cathode Cu under charcoal without addn. of Be or Li are porous and low in mech. properties. Wire made from these has satisfactory cond. and ductility. Cathode Cu melted in CO_2 atm. and cast into vertical molds possesses good mech. properties and d.; wire made from these bars also possesses good mech. properties and good cond. Cu melted in a H atm. is lower in cond. and mech. properties, particularly in the form of cold-drawn or annealed wire. 15 references. B. N. Daniloff

Laboratory test for machinability. A. S. Kenneford. *Metal Ind.* (London) 55, 269–74(1939).—Previous work is reviewed. This paper deals with the Oxford-Airey machine which measures the work required to remove 1 cu. in. of metal. Depth of cut has slight effect on the results; increasing the feed from 0.005 to 0.02 in. decreases the work required by about half. This was true of several alloys tested, including 6% Sn bronze, 80:20 cupro-nickel, 60:40 brass and Mg. Addns. up to 1% Pb to 70:30 and 60.40 brasses reduced the specific work required by half. Further addns. up to 5% Pb had a considerably smaller effect in the same direction. 4 references. J. N. Lynn

Cementation equilibrium and cementation reaction in CO-gas current. Osamu Madono. *Tetsu-to-Hagane* 25, 134–44(1939).—In view of a wrong representation of the cementation equil. by formula $3Fe + 2CO = Fe_3C + CO_2$, M. discussed the fact that the cementation velocity can never exceed the satn. point of solid soln. Agr and the cementation phenomena never occur below the A_1 point. The reason is that Fe is the most conspicuous catalyzer which augments the dissocn. of CO and at the moment of contact with Fe the equil. $2CO \rightleftarrows C + CO_2$ is attained with the instantaneous dissocn. of CO; hence the actual action of pure CO and Fe is impossible even in CO gas current. Fe_3C might, however, occur at a temp. below 500°, as the dissocn. velocity becomes small at a comparatively low temp. The action of cementation in the CO gas current becomes weak when the current velocity becomes small. This is due to the diffusion layer made on the surface of the specimen by CO_2 which is generated by the cementation reaction. M. Ishida

Influence of heating and quenching conditions on mechanical properties and microstructures of high-tensile steel rivets. Genziro Mima. *Tetsu-to-Hagane* 25, 721–33(1939).—Some of the effects of the operation for rivet-making and riveting on the mech. properties and microstructures of high-tensile steel rivets are described. Overheating accentuates blue-brittleness, secondary brittleness and transformation brittleness of high-tensile steel rivet bar. The high-tensile rivets always decrease in tensile strength and elongation with the quenching operation within the blue-brittleness and secondary-brittleness ranges. The best temps. of heating are: for ordinary riveting, 900°; for pneumatic riveting, 1,050° (10–30 sec.) when heating is in an elec. furnace, 1,100° (1–3 sec.) when heating is in a coke-fired furnace. M. Ishida

Heating and liquid quenching massive sections. II. Joseph A. Duma. *Heat Treating Forging* 25, 505–8 (1939); cf. *C. A.* 33, 8541[2].—There are 2 fundamental methods of liquid quenching for steel; these are austempering, and direct quenching in either brine, water and oil baths, or interrupted quenching utilizing 2 baths. Austempering is good for small sections, but has not yet been applied commercially to heavy sections. The second method is almost invariably employed in large work. Cooling data are given and tempering treatments are described. 11 references. I. Hartmann

Continuous wire annealing in open gas flame. Harry W. Smith, Jr. *Heat Treating Forging* 25, 513–16; *Wire and Wire Products* 14, 643–5, 662(1939).—The principle of open flame annealing is outlined and a new app. is described which includes the first continuous wire annealing indicator mechanism. I. Hartmann

A precise method of measuring heat conductivity applicable to either molten or solid metals. Thermal conductivity of zinc. Charles C. Bidwell. *Phys. Rev.* 56, 594–8(1939).—A metal rod or hollow vertical graphite cylinder contg. molten metal is packed in silocel contained in an outer iron cylinder. Downward heat flow is established and vertical and radial gradients are measured differentially by thermojunctions. Previously published values for solid Zn are verified and extended through the m. p. to 730°. The cond. of liquid Zn decreases slightly with rise in temp. H. C. Thomas

Solid impurities in metals. L. Guillet, Jr. *Rev. universelle mines* 15, 511–18(1939).—In general, the non-additive properties, as soln. potential, elec. and thermal

conds., crystn. velocity and mech. properties, are most sensitive to impurities. If the impurity is in soln. in the metal its effect is the greater the farther impurity is from the base material in the periodic system. If the impurity is insol. in the metal a second phase appears which exerts a noticeable effect on corrosion, brittleness and malleability. Numerous examples illustrate the various conditions and effects. Twenty-five references. M. Hartenheim

Motor-car rear-axle design and production. G. W. H. Nash. *Machinery* (London) **54**, 653–6(1939).—Steel S. A. E. 4620 is used for carburized rear axle gears. It is necessary to anneal the gears after forging: heated to 1010°, held for 1 hr., cooled in air blast to 540°, then at 40° per hr. to 315°, then in still air. Both the box and the gas carburizing methods may be used for gears and pinions. In the first case the charge is carburized at 925°, cleaned, quenched in quenching press, and, in some cases, drawn at 135°. The press holds the pieces in a die while they are immersed in the oil to keep them round and flat. If gas carburizing is used the parts are quenched directly from the furnace; no cleaning is necessary. Richard P. Seelig

Restoration of artificially removed or disfigured metal stamps. J. Dettling. *Deut. Z. ges. gerichtl. Med.* **31**, 1–11(1939).—Suitable methods of corrosion can be used to bring marks into temporary or permanent relief which may be photographed. Frances Krasnow

A note on the effect of the addition of molybdenum, tungsten and titanium, together with calcium silicide, to cast iron. J. E. Hurst. *Foundry Trade J.* **61**, 265–6, 280 (1939).—Oxides of the alloying elements Mo, W and Ti were added in powder form to molten refined pig iron, in conjunction with the reducing agent $CaSi_2$. The metal was cast into test bars and expts. were made to det. the modulus of rupture, tensile strength, hardness, etc. The results are tabulated. Of special interest are the very high tensile and transverse strengths obtained by the addn. of CaSi and both MoO_3 and FeMo. CaSi addn. alone reduces the S content, but this effect is greatly enhanced when FeMo or MoO_3 is also added. Addn. of WO_3 does not cause so great an increase in strength nor so marked a reduction in S as MoO_3. Addn. of CaSi and TiO_2 reduces the combined C content considerably, but it has little effect on S or on strength. I. Hartmann

Hydrogen in steel. Sasaburo Kobayasi. *Tetsu-to-Hagane* **25**, 745–73(1939).—Vacuum extn. at 800° is the most suitable for the estn. of H in steel. The sampling of specimens for accurate analysis is discussed. The variation of H_2 and other elements in various stages of steel melting and the means for decreasing H are explained. The relation of H in steel in the course of melting to that in slag was investigated, and the mechanism of intrusion of the H was studied. M. Ishida

Isothermal transformation in steels. Edmund S. Davenport. *Metal Progress* **36**, 623–9(1939).—Illustrated extracts from the annual Campbell Memorial Lecture are given. W. A. Mudge

Manufacture and use of stainless steel wire. Stanley P. Watkins. *Wire and Wire Products* **14**, 527–38(1939). George Ayers

Properties and application of acid-resistant chromium and chrome-nickel steel castings. F. Schulte. *Giesserei* **26**, 477–84(1939).—By addn. of at least 12% Cr to Fe a steel can be produced whose surface can easily be passivated. It is rust-proof and to a certain extent resists oxidizing chemicals, e. g., HNO_3. Eighteen Cr steels resist HNO_3 at elevated temp. within a wide range of concn. The toughness of low-C Cr-steels is low; somewhat higher Cr content and C render heat-treatment possible (e. g., 15% Cr, 0.2% C, f. p. 1400°, practically no interval). These heat-treating steels are somewhat low in impact strength although their elongation is good. Complete nonrusting properties are obtained only with polished surfaces. Rough surfaces form a rust film which does not penetrate further. Applications are: steam armatures, turbine parts, ship propellers, app. for the food industry. 1.5% Ni and 1.5% Mo may be added for safety and better chem. resistance. Higher-C alloys must be used in the hardened condition for best corrosion resistance (e. g., plunger and valve steel with 18% Cr, 0.5% C, 2% Mo, quenched from 1000° in oil, yields 60 Rockwell C). Steels for wear resistance have 1 to 2% C and 14 to 22% Cr; they are rust-proof if hardened (Ledeburite Cr-steels used for pump gears, grinding and pulverizing machinery, etc.). On account of its rust resistance and good castability chrome-casting (1 to 2% C, 30 to 35% Cr) is sometimes used instead of bronze; it is also applied where severe wear and corrosion resistance are required; it stands up well in mixed HNO_3 and H_2SO_4. Cr-Ni steels can be made pptn. hardening by Ti, Be, Al, B addns. This is little used as the resulting heterogeneous structure is less corrosion-resistant than pure austenite. 18/8 with Mo is used mainly in the sulfite wood pulp industry. For H_2SO_4 and HCl, Si castings are usually used (14–16% Si) which are rather brittle. Ten % Cr, 20% Ni, 4% Mo and 4% Cu steel resists H_2SO_4 in all concns. at room temp. and up to 70 and 80° at almost all concns. For highest resistance to HCl Ni-Mo-Fe alloys are used. Richard P. Seelig

The hardening of chromium-molybdenum and chromium-nickel case-hardening steels. A. Pomp and A. Krisch. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch. Düsseldorf* **21**, 309–26(1939); cf. *C. A.* **32**, 7877⁴.—Two Cr-Mo, 1 Cr-Ni-Mo and 2 Cr-Ni steels were case-hardened and the cores of the case-hardened pieces (diams. varying from 5 to 60 mm.) were examd. by hardness (Brinell and Vickers), tensile, notch-impact and fatigue-bending tests. There were only slight differences in surface hardness; these were due to C different contents and chem. compns. Differences over the section were found to 30 units in the 5 10-mm. rods. The hardness of 30-mm. rods was in general 10 units lower than that of 20-mm. rods. The required tensile strength for these steels of 90–110 kg./sq. mm. was reached only in the 5- and 10-mm. rods; the 20- and 30-mm. rods showed only 68–85 kg./sq. mm.; the differences over the section were slight. The ratio of elastic limit to ultimate strength was in all cases not quite 0.70. Elongation at fracture was better in all cases than the required min. of 8–10% and notch-impact strength higher than 7.5 kg./sq. cm. Reduction of area was 47–59%. Most steels had a fine martensitic hardening structure, but some specimens had ferritic spots due to incomplete transformation. The frequency curve of the ratio tensile strength/Vickers hardness is an asymmetric curve with a max. at 0.35; that of tensile strength/Brinell hardness is more regular with the max. at 0.35 and 0.36. M. Hartenheim

A permanent magnetic alloy with anisotropic magnetic properties. H. G. Muller. *Z. Elektrochem.* **45**, 674–8 (1939).—The alloy investigated contained Fe 20, Ni 20 and Cu 60%. It can be homogenized at about 1100° and is made magnetic by quenching from the homogenizing temp. and then annealed for 10 to 20 hrs. at 600° or ½ hr. at 700°. Study of the magnetic properties of this alloy shows that magnetic anisotropy of cold-worked Fe-Ni-Cu permanent magnet alloys is produced by a strained condition which can be attributed to an anisotropic distribution of heterogeneous infiltrations. Crystallographic structure, therefore, has no relation to this anisotropy. The rolled structure and the anisotropic distribution of sepd. phases are both produced by plasticity changes during cold working. H. Stoertz

Abnormal magnetic properties of hardenable alloys. H. Bumm. *Z. Elektrochem.* **45**, 671–4(1939).—The alloys investigated had the compn. Fe 51.5, Ni 35.5, Cu 13 and Fe 50.5, Ni 34.5 and Cu 15.0%. They were heated at 1000° in H_2 for 1 hr. and cooled rapidly in H_2. The effect of heat-treatment upon the initial premeability and the increase in permeability was detd. Resistance measurements show that Cu sepn. occurs while permeability rises. Abnormal permeability increase therefore causes a dispersion of Cu atoms. The consts. of the fundamental lattice are altered, but the sepd. phase is in such a fine state of division that the newly produced lattice is not discernible either microscopically or by x-ray. Only when the sepd. phase is coagulated are new inhomogene-

ous strains produced which cause a decrease in permeability. Variation in heat-treatment and annealing of these alloys produces such changes in magnetic properties that almost any desired combination of initial and increasing permeability can be obtained in this manner. H. Stoertz

X-ray examination of light alloy castings. Sinkiti Sekito and Tomoki Inoue *J. Metals* (Japan) **9**, 559–61 (1939).—Application of x-ray radiography to light alloy castings is described. M. Ishida

Irregularities in the precipitation-hardening curves of aluminum-copper-magnesium alloys. H. Kostron. *Aluminium* **21**, 687–90(1939).—Curves taken with a *new automatically recording hardness tester* of the increase of hardness with time of pptn.-hardening alloys of the Al-Cu-Mg type have shown quite irregular, wavy form which might indicate that periods of hardening and dehardening alternate during storage in room temp. after quenching. A closer investigation of many such curves and expts. with cooling and stressing by different means (bending, rolling) seem to lead to the conclusion that the irregularities are, probably to be ascribed to local deformations which are caused by quenching stresses and by the inevitable straightening after the quenching process The expts. are described. M. Hartenheim

Thermal conductivities of some industrial alloys of copper and of nickel. J. W. Donaldson. *Engineering* **148**, 539–40(1939).—See *C. A.* **33**, 9256[9]. E. J. C.

Columbium-iron alloys. R. Genders and R. Harrison. *Engineering* **148**, 514–15(1939).—See *C. A.* **33**, 8550[5]. E. J. C.

Acid resistivity of iron-nickel-molybdenum alloys. Takezirō Murakami and Tatui Satō *Nippon Kinzoku Gakkai-Si* **3**, 325–7(1939); cf. *C. A.* **33**, 3738[1].—A series of corrosion tests of Fe-Ni-Mo alloys contg. 50%, 60%, 70% and 90% Ni with varying Mo content about 1–10% and a trace of C was examd. in 10% aq. solns. of HNO_3, HCl and H_2SO_4 at 25° by measuring the loss in weight. The effect of Mo on the loss by HNO_3 is remarkable, though that by H_2SO_4 or HCl is very small. Hideo Nishimura

Constitution of the precipitant from the Corson alloy by artificial aging. Masazo Okamoto. *Nippon Kinzoku Gakkai-Si* **3**, 336–48(1939).— As given by M. G. Corson a pseudo-binary system is not formed on the line $Cu-Ni_2Si$ and the Cu solid soln. and the γ' solid soln. coexist in the compn. range of the Corson alloy. Hence the second phase pptd. from the supersatd. α solid soln in the Corson alloys is not the Ni_2Si, but the γ', which is a phase formed by Ni_6Si_2 contg. about 35% as max. of Cu in the form of solid soln. The κ phase existing in the Cu-Si system at the compn. range of Si from about 4.5 to 7.5% does not appear in the Corson alloy. H. N.

Free-turning brass (machinability) Maurice Cook and E. Davis. *Metal Ind.* (London) **55**, 241–5(1939).—See *C. A.* **33**, 9257[6]. *Ibid.* 275–7.—The distribution of Pb particles in extruded rod was quite uniform both microscopically and in machinability ratings. Annealing caused no appreciable coalescence or effect on either of these factors. J. N. Lynn

Electric resistance wires. C. L. Mantell. *Wire and Wire Products* **14**, 543–9(1939).—The manuf. of Ni-Cr, Ni-Cr-Fe and Ni-Cu alloys and of elec. resistance wire is described. George Ayers

Metallic protective coatings. E. Raub. *Mitt. Forsch.-Inst. Edelmetalle staatl. hoheren Fachschule schwab. Gmund* Aug., 1939, 1–16.—A general discussion of theory and practice, particularly from the point of view of the electrochem. theory of corrosion Examples are described of the plating of Fe with Ni and Zn and of Mg and its alloys with Se. M. Hartenheim

Corrosion of various copper alloys in solutions of 0.1 *N* sodium chloride and 0.1 *N* sodium chloride-0.3% hydrogen peroxide. Akira Itagaki and Eizyun Kuwahara. *Nippon Kinzoku Gakkai-Si* **3**, 327–36(1939).—The corrosion resistance of some Cu alloys and a few Ni alloys to 0.1 *N* NaCl-0.3% H_2O_2 solns. was detd. The corrosion resistance of the alloys in the soln. was better, the higher the Ni content. Among the alloys which contains no Ni or a little, Barberite, Silzin Bronze, Ambrac and Tempaloy were comparatively good resistant alloys; the former 2 especially showed a good resistance in both solns. The corrosion resistance of 10% Al-Cu alloy, which showed an excellent resistivity in dil. HCl, was not so good. Hideo Nishimura

Corrosion protection of magnesium and its alloys. B. Wullhurst. *Mitt. Forsch.-Inst. Edelmetalle staatl. hoheren Fachschule schwab. Gmund* Aug., 1939, 16–25.—The protection of Mg from corrosion by alloying with other metals can be obtained only with a limited no. of metals because of its very strongly electroneg. nature (−2.35 v.), that is only with those in its neighborhood in the potential series. Ag, Cu and Ni can, in general, not be used as their soly. in Mg is only slight and an excess of undissolved metal remains which leads by its higher potential to corrosion; they are used only where the alloys cannot come in contact with electrolytes. The most important alloying metals for Mg are Al, Mn, Zn, Si and, lately, Ca. Al and Zn increase mech. strength, Si and Mn produce fine grain, and Mn and Ca especially have a corrosion-retarding effect. An addn. of Pb (0.5–22%) and of 1–10% Cd to Mg alloys with subsequent aging at 175° is said to produce high corrosion resistance (U. S. pats. 2,124,537, *C. A.* **32**, 7012[1], and 2,124,571, *C. A.* **32**, 7012[5]), or also 0.05% Sb or Bi to Al-Mg and Zn-Mg alloys. Be effects an extraordinary increase of corrosion resistance in amts. of 0.005–0.5%; this upper limit is at the same time the max. soly. of Be in Mg. Be makes coarser grain; this can, however, be counteracted by addn. of Ti or Zr, the latter in amts. of 0.005–0.5%. The elements of the alk earth group have also been proposed to reduce corrosion. Ba is used in alloys for the getter material in electron tubes. Ca increases corrosion resistance of Mg considerably; an alloy with 1% Ca does not decompose water vapor, which explains its corrosion resistance in humid air. Mg with 3% Li shows a considerable increase in mech. strength, and corrosion did not take place after a longer time of storage. According to Brit. pat. 489,320 (*C. A.* **33**, 1171), Mg alloys with 1–5% K or Na are proposed. Protection of Mg by coatings of fluorides, phosphates, silicates and chromates are often used now, especially chromates and phosphates; methods for their production are described. Electrochem. generation of protective films, similar to the eloxation process for Al, have given a limited success; a good adhesion is difficult to obtain and requires very careful pretreatment of the metal. Methods are described, especially for elec. treatment of an alloy of 97.08% Mg with 2.5% Mn, 0.045% Fe and 0.01% Cu in *N* NaOH soln. with d. c. M. Hartenheim

Cold welding of silver. II. G. R. Van Duzee and J. M. Thomas. *Trans. Electrochem. Soc.* **77**, 9 pp. (preprint)(1940).—Pressure welding of Ag sheet was studied at temps. from room temp. to red heat. By preheating the Ag to redness, then allowing it to cool, complete welds were secured at room temp. both with "999.3 fine" Ag and with spectroscopically pure Ag. When the spectroscopically pure Ag was preheated, complete welding took place at room temp. under a pressure of 4950 kg./sq. cm. applied for 30 sec. Similarly treated 999.3 fine Ag sheet showed only slightly lower weldability. The spectroscopically pure Ag which had not been preheated before welding showed a much lower weldability than when heated to redness immediately before pressure was applied. When there had been a preheating treatment, welds were obtained consistently when 4950 kg./sq. cm. was applied for 30 sec.; without preheating no welds at all were formed under the same conditions and the welds formed under a pressure of 7000 kg./sq. cm. applied for 30 sec. were unsatisfactory. Good welds were obtained, however, at 9100 kg./sq. cm. Comparative tests with Au sheet showed similar advantages obtained by heating to redness before pressure application. Results of welding tests with 999 fine Ag powder and "proof" Ag powder are given. C. G. F.

Soldering of light metals. R. Schulze. *Aluminium*

21, 710–12 (1939).—Soft-soldered joints often show a poor adhesion of solder to metal. Numerous solders in the market are investigated with regard to compn., m. p. and metallization. Most solders are based on Zn, Sn or Cd and contain Cu and Ag. Sn and Cd up to 50–80% are present in some with m. p. between 120 and 260°. Zn solders with addns. of Cu and Ag m. 400–500° and have a hard-solder character Al solders with low m. p. do not destroy the oxide film and give satisfactory joints only if they are brushed on with a hard wire brush and overheated very strongly. This, however, injures the base metal. Sn-rich solders have too low a m. p.; those rich in Zn have m. p. that is too high so that hardened metals are softened. The most suitable temp. for soldering as far as the base metal is concerned is about 300°, for then the oxide film is easily removed and a good metallic connection between solder and metal obtained. The solder should have a similar m. p. and a narrow melting range, and should flow readily and alloy easily with the Al base. The eutectic Al-Zn alloy (Ger. pat. 677,568, *C. A.* **33**, 9278[7]) with addn. of Sn and Cd fulfils these requirements. The tensile strength of such butt joints is 3 kg /sq. mm. Overlapping joints (about 12 mm.) gave with Al-Cu-Mg sheets a tensile strength of 32 kg./sq. mm. referred to the section of the specimen with fracture through the joint. Photomicrographs of etchings show the transition zones of the joints. M. Hartenheim

Wire solder—its manufacture and uses. Robert A. Gardiner. *Wire and Wire Products* **14**, 551–2 (1939).—The history, development and uses of wire solder are discussed. George Ayers

Froth flotation of ores. Wolf Kritchevsky (to Ninol, Inc.). U. S. 2,173,909, Sept. 26. An ore such as an oxidized Pb ore contg. Au in quartz is subjected to froth flotation in the presence of an aq. medium contg. a relatively small proportion of a condensation product of an alkylolamine such as mono-, di- or tri-ethanolamine and a higher org. acid substance such as stearic or oleic acid. Numerous examples are given. 6

Treating ore deposits such as those of copper ore with circulating molten sulfur in mining operation. Howard L. Reed (11.3% to Fohs Oil Co.). U. S. 2,172,683, Sept. 12. App. is described, and a method of circulating molten S through an ore deposit and treating the S as it comes from the deposit to remove minerals which it has taken up. 7

Treating ores and tailings for recovery of metals such as gold and silver. John Allingham (50% to Wm. N. Rossberg). U. S. 2,173,090, Sept. 19. App. is described, and a process in which a fluid ore pulp is subjected in the presence of an electrolyte to the action of a mass of materials such as particles of Fe and Zn forming a voltaic couple and of a size such that the materials are brought into intimate contact with the mass, thereby depositing mineral particles on one of the couple materials, these particles being then sepd. from the couple into the fluid pulp and the pulp being sepd. from the couple, and the particles being finally recovered from the pulp. 8

Apparatus for utilizing molten lead for separating gold from sand. Albert Trayman. U. S. 2,172,718, Sept. 12. Various structural and operative details. 9

Treating iron ores. Kaiser-Wilhelm-Institut fur Eisenforschung e. V. Brit. 507,572, June 14, 1939. A magnetic ore-dressing process for $FeCO_3$ ores comprises roasting the ores in an atm. that contains no O or only a small quantity of free O, cooling and finally submitting to a magnetic sepn., the cooling of the hot roasted material being effected by means of a gas that contains no, or almost no, free O, the max permissible O content in each case being 1.8%. In a modification, the cooling below 550° may be effected in a gas contg. free O, e. g., air. The roasting temp. may be 600° and the roasting period 25 min.–3 hrs. The cooling atm. may be a mixt. of N_2 and CO_2, with or without 3% of CO. Cf. *C. A.* **33**, 1256[9].

Obtaining uranium and vanadium from ores. Ralph D. Nye and Dana J. Demorest (to Utah Alloy Ores, Inc.). U. S. 2,173,523, Sept. 19. A process of obtaining U and V from their ores involves subjecting the ore to crushing, sepg. desired mineralized fines normally contg. aluminous material and acid neutralizing elements by a dry pneumatic sepn., subjecting the remaining mineralized tailings only from such sepn. to a moistening and dampening treatment with an acid reagent such as a dil. H_2SO_4 soln., storing the acid-treated tailings in piles to age them and permit reaction of the acid with U and V compds. present, and dissolving out the desired metal values. An arrangement of app. is described. 3

Apparatus for melting metals such as magnesium. Claire S. Harris (to Dow Chemical Co.). U. S. 2,173,063, Sept. 12. An app. for melting readily oxidizable metals such as Mg and its alloys comprises a melting pot, a double-walled dome-shaped cover for the pot, the walls of which are spaced apart to form a closed chamber in which to generate a protective gas or vapor, with an aperture through both walls of the cover of sufficient size to admit a ladle (various other structural details also being described). 4

Roasting metal sulfide fines such as those of iron. Bernard M. Carter (to General Chemical Co.). U. S. 2,174,185, Sept. 26. An arrangement of app. is described, and a method which comprises introducing metal sulfide fines, metal sulfate fines and oxidizing gas into a combustion zone heated to above the ignition point of the sulfide fines, forming in the combustion zone a dispersion of the sulfide and sulfate fines in the oxidizing gas, roasting the sulfide fines while in gaseous suspension, regulating the amount of sulfate introduced so as to avoid reducing combustion zone temp. below that at which sulfide fines introduced into the combustion zone ignite and oxidize in the presence of O, causing the sulfide and sulfate fines to pass through the combustion zone so as to maintain such fines in suspension for a sufficient time interval to roast the sulfide fines and to decompose the sulfate fines to form from the sulfide and sulfate fines SO_2 gas and substantially desulfurized metal oxide cinder, withdrawing SO_2 from the combustion zone, and discharging cinder therefrom. 5

Shaft furnace for fusing metals. Wolfgang Zoller. Ger. 678,261, July 12, 1939 (Cl. 31*a*. 1.01). Addn. to 676,804 (*C. A.* **33**, 7264[2]).

Insulated wall for open-hearth furnaces. Edward J. Parsons. U. S. 2,173,764, Sept. 19. Various structural features.

Bessemer converters. Herman A. Brassert and H. A. Brassert & Co. Ltd. Brit. 507,200, June 8, 1939. In a Bessemer converter having a tuyère box of circular cross-section, the plain upper face of the bottom merges into the spherical wall portion, this portion also merging into a frustoconical belly portion, and the ratio of the vol. of metal in an imaginary cylinder above the tuyères to the vol. of the annulus surrounding this cylinder is not greater than 3.1 in a newly lined converter, this ratio applying to all cylinders and annuli extending up to the max. diam. of the converter. At the height of the bath at the max. diam., which in ordinary converters is 750 mm. above the bottom of the converter, the ratio of the radius of the converter to the radius of the tuyère box is not less than 3:2.

Twin oven unit for annealing castings for malleableizing. Cecil F. Herington (to Amco, Inc.). U. S. 2,173,586, Sept. 19. Various structural features.

Apparatus for continuous extrusion of metals such as lead or its alloys, as in forming electric cable sheaths. Percy Dunsheath (to Henley Extrusion Machine Co., Ltd.). U. S. 2,172,651, Sept. 12. Various structural, mech. and operative details.

Reclaiming manganese from blast-furnace dust in manganese alloy production. Charles B. Francis. U. S.

2,173,535, Sept. 19. Mn-bearing dust is sepd. from blast-furnace gas, mixed with an Fe oxide waste or by-product from the steel mills, and the mixt. is formed into small compact masses, charged into a basic steel-making furnace, and resulting slag is tapped from the furnace and is re-charged into the blast furnace.

Metal powders suitable for making electrical brushes, bearings, etc. Joseph E. Drapeau, Jr., and James O. Johnstone (to Glidden Co.). U. S. 2,173,100, Sept. 19. A substantially dry, nonsegregating, free-flowing metal powder such as mixed Cu and Sn has assocd. with it about 0.0025–0.03% of a nonreactive liquid such as kerosene which serves to inhibit segregation.

Apparatus for polishing metal powders. Henry H. Mandle. Brit. 508,485, June 30, 1939.

Iron powder. Deutsche Gold- und Silber-Scheideanstalt vormals Roessler. Brit. 507,277, June 13, 1939. In the production of Fe powder by the reduction of Fe oxide by H, powd. Fe is moistened with H_2O in the presence of small quantities of an Fe halide, e. g., $FeCl_3$, and exposed to the action of the air, preferably with stirring, a moderate temp., e. g., 120–200°, being maintained, the oxidation product so obtained being reduced by H at 500–600°. Before reduction, the oxidation product may be heated to 350–400°, preferably in the presence of air, e. g., in a rotary furnace.

Magnesium. Henri L. Gentil. Brit. 506,485, May 30, 1939. Oxidized compds. of Mg are reduced by means of a sulfide of a metal that is nonvolatile at the temp. of reduction, e. g., Fe, Mn, Ni, Sn. If Sn sulfide is used, the Sn can be completely sepd. from the other elements present and recovered. The reaction may be conducted under reduced pressure.

Treatment of anodized magnesium. Robert W. Buzzard. Brit. 506,466, May 30, 1939. The corrosion resistance of coatings produced on Mg or Mg base alloys by anodic treatment is improved by immersion in a hot acid-reacting soln. contg. (a) a chromate or dichromate and (b) a sol. sulfate, phosphate, borate or fluoride or a salt of Cr or Mn or a combination of these salts. Suitable baths contain (1) $Na_2Cr_2O_7$, $K_2Cr_2O_7$ or $(NH_4)_2Cr_2O_7$ 1–30 with $MnSO_4$ 8–12 or CrF_3 0.25–10%, (2) $Na_2Cr_2O_7$, $K_2Cr_2O_7$ or $(NH_4)_2Cr_2O_7$ 8–12 with Na borate 3–7 or Na phosphate 8–12% and (3) $ZnCrO_4$ 1–3, $Na_2Cr_2O_7$ 3–7 and CrF_3 1–3%. The treatment may comprise immersion in a bath contg. a chromate and (or) dichromate and a phosphate followed by immersion in a bath contg. a dichromate, $MnSO_4$ or CrF_3.

Extracting nickel from nickel-copper mat. I. G. Farbenindustrie A.-G. Brit. 507,792, June 23, 1939. Ni-Cu mat, prior to extn. of Ni by acids, salt solns., chlorination or a carbonyl process, is subjected to a protracted heat treatment in a neutral atm. at 400–900°, whereby the soly. and reactivity of the Ni are increased.

Extracting chromium from alloys of iron and chromium. Marvin J. Udy. Brit. 507,558, June 16, 1939. The alloys, which may be in scrap or other form, are treated at a melting temp. with CaO and SiO_2 under oxidizing conditions so that Cr is selectively oxidized to form a molten Ca silicochromite of formula $3CaO.Cr_2O_3.nSiO_2$, where n is less than 3, and a metal contg. unoxidized Fe and, if desired, some Cr. The process may be conducted in an elec. furnace, blast furnace or converter and the CaO and SiO_2 may be added as limestone and quartzite, resp. The oxidizing agent may be O, CO_2, Fe_2O_3 or Fe ore. Sufficient coke should be present to maintain a concn. of CO to prevent oxidation of the Fe, and the exothermic nature of the reaction may be increased by the addn. of Si, Fe-Si or an oxidizing agent such as $NaNO_3$. The silicochromite may be used in the manuf. of chromates, dichromates, CrO_3, Cr_2O_3 and $Cr_2(SO_4)_3$, or in making Ni-Cr and Co-Cr alloys, pure Cr (by reduction with Si in the presence of addnl. CaO), or alloys of Cr and Fe. In the latter case, the silicochromite may contain Fe and is granulated, briquetted with a nonearbonaceous reducing agent, e. g., Fe-Si or Si, and added to a bath of low-C steel. Cf. *C. A.* **33**, 1259[9].

Beryllium articles. Deutsche Gold- und Silber-Scheideanstalt vormals Roessler. Brit. 508,028, June 23, 1939. See Fr. 831,520 (*C. A.* **33**, 1651[2]).

Cleaning and oiling metal. Morris D. Stone (to United Engineering and Foundry Co.) Brit. 507,692, June 20, 1939. The rusting of metal articles that may occur during the normal method of drying after a hot-H_2O rinse subsequent to pickling and prior to oiling is avoided by rinsing them in cold H_2O after the pickling and then, without permitting them to dry, oiling them.

Phosphoric acid baths. René J. Kahn. Brit. 507,355, June 14, 1939. See Fr. 829,686 (*C. A.* **33**, 1258[3]).

Preparing hard metals such as tungsten, columbium or vanadium and mixed carbides such as those of these metals. Gustav Boecker and Johann G. Boecker (to Charles A. Bolton). U. S. 2,173,749, Sept. 19. A mixt. of materials such as W, Cb, V and C is subjected to heat treatment at progressively increasing temp. in stages, the temp. stages corresponding to the temps at which the individual constituents most readily combine (suitably about 1450° and 2200°).

Hard metal carbide articles. Metal Carbides Corp. Brit. 506,728, June 1, 1939. See U. S. 2,167,544 (*C. A.* **33**, 8557[2]).

Creep-resistant structural elements subject to high temperature in use, such as oil-still-tube supports. Edmund M. Wise and James T. Gow (to International Nickel Co.). U. S. 2,174,025, Sept. 26. Load supporting elements are made of a creep- and heat-resistant austenitic Cr-Ni-Fe alloy having an austenitic matrix and relatively stable fine carbides distributed in the grains, the alloy contg. Fe together with Cr 10–30, Ni 8–50, C 0.25–0.75, and Cb 0.5–3%, such elements having a creep rate in the second stage less than 0.00024% per hr. under a stress of 2000 lb per sq. in. at a temp. of about 980°.

Treating metal sheets with liquids. Remy, van der Zypen & Co. Brit. 508,086, June 26, 1939. In pickling, rinsing, and other treatment of metal sheets, the sheets being guided in guiding members through the liquid contained in a tank, the sheets are, to protect the parts thereof that lie upon the guiding members, during their passage through the liquid lifted wholly or partly from the members by means of the liquid itself producing a lift upon the sheets.

Magnetic material in sheet form and of high permeability. Gunter Wassermann (to Siemens & Halske, A.-G.). U. S. 2,173,240, Sept. 19. A method of mfg. magnetic materials of high permeability in sheet form from materials such as Fe with body-centered cubic atom lattices consists in first cold rolling the specimen to reduce it to about one-eighth to one-tenth of its original thickness, subsequently cold rolling it in a direction 90° from the first rolling direction to reduce it to about half the thickness attained after the first rolling, and then heat-treating at a temp. of 600–1000°.

Preparing metals such as steel for working, as by rolling or drawing. Michael W. Freeman. U. S. 2,172,533, Sept. 12. The surface of the metal is treated with a soln. having as its principal active constituent an org. sulfonic acid which is substantially devoid of inorg. acid content, and which serves as a lubricant. Numerous examples are given.

Melting and refining steel in an open-hearth furnace. Wm. A. Morton and Howard F. Spencer (to Amco, Inc.). U. S. 2,173,592, Sept. 19. Details of furnace construction are described and of a method of melting and refining steel in an open hearth furnace which comprises placing a charge on the hearth structure, directing a melting flame to substantially the level of the charge from opposite ends of the charge to blanket the charge with the products of combustion and withdrawing the products of combustion downwardly through substantially the center of the charge to keep the heating medium in intimate contact with the charge at all times.

Deoxidizing steel. Röchling'sche Eisen- und Stahlwerke G. m. b. H. Brit. 508,012, June 20, 1939. This corresponds to Fr. 831,275 (*C. A.* **33**, 2476[3]).

Deoxidizing steel baths. Otto Johannsen (to Röchling'sche Eisen- und Stahlwerke G. m. b. H.). U. S. 2,173,205, Sept. 19. For deoxidizing finished steel out-

side the furnace, use is made of a mixt. of CaC_2 40–60 and fluorspar 60–40%, suitably with cryolite 10%.

Composite bearings of steel and Babbitt metal or the like. Randolph L. Strickland and Jerome J. Frank. U. S. 2,173,985, Sept. 26. Various structural details.

Preparing steel bumper bars, etc., for nickel and chromium plating. Edwin M. Baker (to Houdaille-Hershey Corp.). U. S. 2,173,092, Sept. 19. A method of prepg. steel bumper bars, etc., for subsequent Ni and Cr plating (with need for polishing largely eliminated) involves hot rolling an ingot of Cu alloy steel contg. Cu 0.5–3.0 and C 0.05–0.7%, air quenching the resulting semifinished sheets to retain the Cu content in soln. in the alloy, pickling, cold rolling and forming the semifinished sheets into bumper bars, cleaning the bars and subjecting them in a nonoxidizing environment to heat treatment to effect pptn. of the Cu content while maintaining the smooth surface characteristics of the bars produced by cold rolling.

Lining vessels such as those of steel with a different metal. Wayne A. Howard and Turner C. Smith (to Socony-Vacuum Oil Co.). U. S. 2,172,819, Sept. 12. Various mfg. details for utilizing sheet metal linings.

Alloy steels. Schoeller-Bleckmann Stahlwerke A.-G. Brit. 506,640, May 26, 1939. Welded constructional elements, e. g., for aircraft, having a min. strength at the weld of 60 kg. per sq. mm. without brittleness are made from steel capable of pptn.-hardening and contg. C 0.05–0.25, Mn 0.3–0.8, Si 0.1–0.5, Mo 0.2–2.0, V 0.1–1.0 and Cu 0.25–3.0%, but no Ti. The steel may be subjected to pptn. hardening by being tempered at about 400–800°, with or without a previous normalizing treatment, or it may be normalized only. In Brit. 506,641, May 26, 1939, the steel contains C 0.05–0.25 and Cu 0.25–5.0 with 1 of the following addns.: Mn 0.8–10.0, Si 0.5–3.0, Cr 0.2–3.0, Ni 0.5–5.0, Mo 0.5–3.0, V 0.2–1.0, W 0.5–3.0, Zr 0.1–0.5 or P 0.1–0.5%, but no Ti. Two or more of the addnl. elements may be present in lesser quantities to give the desired properties.

Steel alloys. Fried. Krupp A.-G. Brit. 506,905, June 6, 1939. Articles that have to be welded during manuf. at 500–900°, e. g., parts of chem. or cooking app., spoons, forks, knives and parts for interior decoration, are made from austenitic steel alloys contg. Cr 10.5–16, Mn 10.5–15, N 0.05–0.35 and C up to 0.15%, with or without Ni 2.5% and with or without up to a total of 3% of Ti, Ta, Cb, V, W, Mo, Zr, Co, Si, Cu and (or) Al.

Steel alloys. Kohle- und Eisenforschung G. m. b. H. Brit. 507,321, June 9, 1939. Articles that do not readily rust are produced from steel or Fe that contains more than 0.11% S and 0.3–1% Cu, with C in normal proportions, the remainder being Fe, with or without Si 0.2% or less and Mn not exceeding 1%. Addns. of P 0.06–1 and (or) Cr up to 1% may be made to the alloy.

Alloy steels for high-speed tools. Deutsche Edelstahlwerke A.-G. Brit. 507,983, June 23, 1939. These contain C 0.7–1.8, Ta and (or) Cb 2.1–15 and V 0.3–5%, with or without Cr up to 6, Co up to 20 and W and (or) Mo up to 5%. The Ta or Cb may be partly replaced by the same amt. of Ti.

Alloys. Henry L. Whitman. Brit. 507,903, June 16, 1939. See Fr. 830,183 (*C. A.* **33**, 1259[7]).

Alloys for electrical leading-in wires, etc. Paul Schwarzkopf. U. S. 2,172,548, Sept. 12. There are used together Ni about 20–30, Co about 10–20 and Fe about 50–70%, with impurities such as Si, Mn and C below 0.3%, the components being sintered together in their "chemically purest" state at about 1300–1400°.

Alloys for resistance wire for electric heaters, etc. British Driver-Harris Co. Ltd. and Wm. M. Kay. Brit. 507,167, June 12, 1939. Alloys of the type comprising Ni and Cr or Ni, Cr and Fe, with or without W, Mo, Co, Mn, Al or U, contain also Th 0.01–2 and Si 0.25–3%, with or without any of the following: a rare earth metal, e. g., Ce, 0.01–2, alk.-earth metal, e. g., Ca, 0.01–0.5 and Zr 0.01–1%. Mg to the extent of 0.01–0.5% may be added for deoxidizing purposes.

Magnetic alloy. Siemens & Halske A. G. (Hans Neumann, inventor). Ger. 678,161, July 10, 1939 (Cl. 40*b*. 14). Addn. to 676,838 (*C. A.* **33**, 7268[9]). An alloy with a high permeability and small coercive effect consists of Fe, Ni and Cu in which 1–10% of the Fe is replaced by Mo. A suitable alloy contains Ni 69, Cu 17.5, Fe 10.5 and Mo 3%.

Aluminum alloy. N.-V. Philips' Gloeilampenfabrieken. Brit. 507,382, June 14, 1939. Electrodes of elec. discharge devices starting with a glow discharge that changes to an independent arc are of Al contg. 5% of Mg.

Aluminum alloy. Rolls-Royce Ltd. Ger. 679,860, Aug. 16, 1939 (Cl. 40*b*. 18). An alloy very resistant to fatigue consists of Fe 1.65–3.0, Mg 0.7–2.2, Cu 0.5–2.5, Si 1.0–3.0% and the rest Al. If the alloy is to be used for slide bearings, 2.2–3.45% of Mg_2Si is added. The alloy may also contain up to 0.2% of Ni. Cf. *C. A.* **33**, 6786[5].

Aluminum-nickel alloys. Metallurgica Bresciana già Tempini. Brit. 506,571, May 31, 1939. The alloys are prepd. by bubbling gaseous $Ni(CO)_4$ through molten Al. The CO liberated has a degasifying and deoxidizing effect.

Copper alloys suitable for electric conductors. Werner Hessenbruch (to Heraeus-Vacuumschmelze A.-G.). U. S. 2,172,639, Sept. 12. Cu is used with Be 0.5–2.5 and Co 0.1–1%.

Copper alloys suitable for welding electrodes, etc. Franz R. Hensel and Earl I. Larsen (to P. R. Mallory & Co.). U. S. 2,173,254, Sept. 19. Alloys of Cu with 0.05–3% of Be and 0.002–0.1% of Li are used with or without Ag, Co, Mn or Cd 1%.

Magnesium alloys. Fritz Christen. Brit. 507,294, June 13, 1939. See U. S. 2,166,039 (*C. A.* **33**, 8166[2]).

Alloys containing palladium, silver, etc. James A. Kilgallon. U. S. 2,172,512, Sept. 12. Alloys which are suitable for use in dental work contain Al 1.5–1.75, Cu 10–15, Ag 30–45, and Pd 58–38 parts.

Resilient articles such as springs from alloys containing nickel and iron, etc. Robert B. Wasson and Alfred V. De Forest (to John Chatillon & Sons). U. S. 2,174,171, Sept. 26. An annealed alloy which may contain Ni about 35–37, Fe 50–60, Cr 7–8, Mn 0.45–0.75, Mo 0.35–0.65, Si 0.3–0.6, and C not over 0.2% is cold worked to reduce its cross section "by over about 85%," and is hardened by heat treatment.

Silicon-iron alloys suitable for use in electric transformers, etc. Wilhelm Rohn and Werner Hessenbruch (to Heraeus-Vacuumschmelze A.-G.). U. S. 2,173,312, Sept. 19. Alloys having a relatively low energy-loss measurement of between 0.48 and 0.60 w./kg. contain Fe together with Si 2–5% and small but effective amts. up to 0.8% of at least one of the metals Cu, Al, Zr and Ti, are substantially free from metallic compds. of O, N and H and are degasified under reduced pressure.

Magnetic material for use in powder cores and the like. Jacob L. Snoek (to N.-V. Philips' Gloeilampenfabrieken). U. S. 2,172,626, Sept. 12. An alloy is used contg. Fe together with Si 7–9 and Mn 6–11%.

Coating metals. Institut für physikalische Chemie der Metalle am Kaiser-Wilhelm-Institut für Metallforschung. Brit. 507,341, June 14, 1939. To avoid the formation of brittle intermetallic compds. when introducing a metal B into the surface of a metal A by cementation there is used instead of B itself an alloy of A with B that corresponds approx., and preferably exactly, with the compn. of that intermetallic compd. that in accordance with the phase diagram of the system A-B is coexistant as a sep. phase with A or with the solid soln. of A with B, if any, rich in A. Instead of the alloy, a mixt. of the components in the same proportions may be used. If it is desired to introduce into A 2 or more metals B, B_1, B_2, etc., the compn. of the cementation powder will depend on whether B_1, B_2, etc., form or do not form compds. with A. If A contains alloying constituents A_1, A_2, etc., the cementation material may or may not contain these metals according to whether it is or is not desired to prevent diffusion of these constituents. Cf. *C. A.* **33**, 1261[5].

Coating magnesium and its alloys. The Dow Chemical Co. Brit. 506,836, June 6, 1939. A protective and

decorative coating is formed upon articles of Mg or of its alloys by treatment with an aq. soln. contg. $Cr_2(SO_4)_3$ and an alkali metal chromate or dichromate. The soln. preferably contains 1–20% alkali metal chromate and 0.5–20% $Cr_2(SO_4)_3$. K or NH_4 chromic sulfate may be the source of the $Cr_2(SO_4)_3$. Other salts, e. g., NaCl, $MgCl_2$, Na_2SO_4, $MgSO_4$, may be present. The article, e. g., a Mg alloy with Al 10, Mn 0.1 and Si 0.5% is cleaned, immersed in the soln. for 0.5–60 min., rinsed and dried. 1

Coating with metals. Siemens-Schuckertwerke A.-G. Brit. 508,014, June 20, 1939. A firmly adhering metal coating adapted to form a foundation for a soldered or welded joint is applied to a ceramic body by first heating the body to a temp. at or near, preferably immediately below, the m. p. of the metal to be applied, and then applying the metal by spraying, e. g., by the Schoop process. The coating applied by spraying may be thin, and may be brought to the required thickness by means other than spraying, e. g., electrolysis. In the preferred method, a nonmetallic intermediate layer, e. g., a glaze, is first applied to the ceramic body, this layer having a softening point that lies below the m. p. of the metal coating so that it is softened during the preheating. When coating with Fe, glazes such as feldspar glazes having softening temps. of about 1200° may be used; for coating with Cu the softening temp. of the glaze may be about 900°. When a metal member is to be soldered onto the coated ceramic body, the softening temp. of the glaze should be above the m. p. of the solder. 2

Coating with metals. Mitteldeutsche Stahlwerke A.-G. Brit. 508,117, June 27, 1939. In coating tubes, sheets and other Fe articles by the Pb-Zn process, wherein the objects are introduced into the Pb and withdrawn through the layer of Zn floating on the Pb, the objects are introduced into the Pb bath immediately after pretreatment with an aq. soln. of NH_4Cl and $ZnCl_2$, which are preferably in the proportions 1:5–10. The container for the molten bath is preferably made of Fe poor in C and the articles are introduced into the Pb through a frame made of a material not attacked by Pb or Pb-Zn alloy.

Hard facings on surfaces such as steel, bronze, monel or aluminum. Robert L. Lerch and Wm. A. Wissler (to Haynes Stellite Co.). U. S. 2,173,484, Sept. 19. For producing a wear-resistant coating of substantial thickness on a metal article, successive portions of the surface of the article are melted to an appreciable depth by use of a gas welding flame, with simultaneous impingement of particles of difficultly fusible material such as W carbide or Si carbide, and the hard-faced surface thus formed is subsequently covered with a layer of fusion-welded matrix metal deposited from a welding rod, the cycle of operations being repeated to produce a surface layer of desired thickness and desired ratio of surfacing materials. App. is described. 3

Testing the thickness of metal coatings such as zinc, bronze, nickel or copper on steel, etc. Sydney G. Clarke (to British Non-Ferrous Metals Research Association). U. S. 2,174,053, Sept. 26. App. is described, and a method of testing the thickness of a coating of metal deposited on a basis metal, by causing a continuous stream of a corroding liquid under const. head to impinge upon a spot in the coating and measuring the time or amt. of liquid required to penetrate the coating, the liquid used being a soln. contg. $FeCl_3$, $CuSO_4$ and HOAc in specified proportions. 4

Hot galvanizing ferrous metal articles such as wire or strip metal. John R. Daesen and Albert F. Bradley (to Northwestern Steel and Wire Co.). U. S. 2,172,933, Sept. 12. App. is described, and a process of hot galvanizing a ferrous metal article involving passing the article through a molten Zn bath maintained at a temp. of about 455–480° to form a Zn coating on the article and then heat-treating the coated article in a molten salt bath at the same or a higher temp. to increase the ferro-Zn alloy content of the coating. 5

Apparatus (with a rotary cylinder) for recovering metals such as the zinc of galvanizing coatings. Claude E. Bowers. U. S. 2,173,546, Sept. 19. Various details of an app. suitable for treating scrap galvanized metal with an H_2SO_4 soln. 6

Soldering, brazing and welding. The Automatic Gasflux Co. Brit. 507,632, June 16, 1939. In soldering, etc., by a gas torch, a liquid fluxing-agent other than an alkyl borate is entrained as a vapor in the gas supplied to the torch so as to provide a fusible stable flux that flows over and covers the heated area and is not oxidizable or corrosive. Thus, either the combustible gas or the oxidizing gas may be bubbled through a fluxing agent dissolved in a vaporizable solvent or through a vaporizable ester of an inorg. acid other than an alkyl borate. App. is described. 7

Soft soldering of aluminum and aluminum-magnesium alloys. Fritz Kohler, Eduard Rouette and Wilhelm Standop. U. S. 2,172,979, Sept. 12. A soldering compn. is used comprising a complex salt contg. a stannic halide and a hydrohalide of a H-rich amine base such as triethylamine-chlorostannate in reactive combination with at least one stannous halide such as $SnCl_2$ and at least one Zn halide such as $ZnCl_2$, and during the soldering procedure forms a vaporizable compd. and a Sn-Zn alloy. 8

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

Molecular structure of aliphatic compounds and their boiling points. E. Neyman-Pilat. *J. Am. Chem. Soc.* **61**, 3235–6(1939); cf. Kinney, *C. A.* **33**, 1261[8].—A discussion of the method of K. for the detn. of "boiling-point numbers." **Calculation of the boiling-point numbers of aliphatic compounds.** Corliss R. Kinney. *Ibid.* 3233–7.—A reply. C. J. West

Relationships between absorption spectra in the ultraviolet and the constitution of organic compounds. Karl Dimroth. *Angew. Chem.* **52**, 545–56(1939).—A comprehensive discussion covering the following subjects: theory and measurements, the C:C bond in aliphatic compds., aromatic compds., the C:O group and the carboxyl group. Applications to polyenes, sterols and steroids are presented. Many data and over 77 references. Karl Kammermeyer

The determination of branched isomers in mixtures of paraffin hydrocarbons. Ulrich von Weber. *Angew Chem.* **52**, 607–10(1939).—The method is based on the following factors: branching depresses the b. p. of the normal compds. by an av. of 7° per unit of branching; the degree of branching is expressed by the branching no. Z, which is defined as the mol. fraction of branches, i. e., Z for n-C_7H_{16} is zero, for 2,4,4-trimethylpentane $Z = 3$, and for a 50% mixt. of the two $Z = 1.5$; the paraffins form ideal solns. with each other, i. e., follow Raoult's law. The detn. of Z is carried out as follows: the paraffin mixt. is fractionally distd., in a column having at least 10 theoretical plates, with a reflux ratio of 10:1. The gaseous components are boiled off before fractions are taken. The fractions are cut at 5° above the b. p. of the normal paraffins: at 41, 74; 103, 131, 156, 175 and 200°. Each fraction n should contain at least 10 cc. The amt. G_n, the mol. wt. M_n and b. p. Kp_n are detd. The evaluation is based on a diagram of temp. T vs. M_n. The points corresponding to Kp_n and M_n of the normal paraffins are connected by a series of straight lines (points are: 36.0, 72.1–86.1, 68.8–98.4, 100.1–125.6, 114.1–150.7, 128.2–173.8, 142.2–195.8, 156.2). This curve represents the calibration curve. The Z no. Z_n of the individual fractions is obtained from the equation: $Z_n = \frac{[T_0 - Kp_n]}{7.0}$, where T_0 is the temp. taken from the calibration curve which corresponds to M_n. The Z no. of the whole distil- 9

late is obtained by: $Z = \Sigma Z_n \frac{U_n}{M_n} \Sigma M_n/\Sigma G_n$. App. for the fractional distn. and the detn. of Kp_n on small samples are described. Data, diagrams and 20 references are given.
Karl Kammermeyer

Isolation of 2,2-dimethylbutane from natural gas and determination of its physical properties. Mildred M. Hicks-Bruun, Johannes H. Bruun and W. B. Mason Faulconer. *J. Am. Chem. Soc.* **61**, 3099–101 (1939).—Previous work (*C. A.* **32**, 855[6]) indicated the presence of 2,2-dimethylbutane (I) in the 38–58° cut from the natural gas originating in the Clendenin Field in W. Va. Details are given of the method of distn. of this fraction and the isolation of I, b. 49.72 ± 0.03°, f. p. −98.7 ± 0.2°, 1st transition point −99.7° (?), 2nd transition point about −146°, d_4^{20} 0.6494, d_4^{25} 0.64475, n_D^{20} 1.3689, n_D^{25} 1.36615. The calcd. amts. of isomeric hexanes in natural gas are: I 168 ml. of liquid per cu. m. of natural gas; 2,3-isomer 74, 2-methylpentane 420, 3-isomer 196. C. J. West

The mechanism of the oxygen effect on hydrogen bromide reacting with ethenoid compounds. Yosiyuki Urusibara and Osamu Simamura. *Bull. Chem. Soc. Japan* **14**, 323–36 (1939). –Based upon expts. involving the action of HBr and O on (1) catechol, (2) allyl bromide and (3) stilbene, the conclusion is drawn that in either normal or abnormal addn. of HBr to double bonds the H or Br atom of the HBr first adds to the particular C atom assocd. with the least steric hindrance, giving momentarily a free radical which may (1) react with HBr, liberating either Br or H (depending on the atom already added) and consequently initiating a chain reaction, or (2) react with O to give a peroxide, which may oxidize HBr to H_2O and Br which in turn adds to another double bond to give a di-Br deriv. The normal reaction requires that H be added first, the abnormal requires Br addn., both reactions probably being chain reactions. Pt black as well as ferromagnetic catalysts such as reduced Fe or Ni accelerate the normal reaction. Normal and abnormal reaction chains may cancel one another (during the induction period), the one which remains in excess being propagated freely. Cis-trans isomerization of isostilbene to stilbene by HBr and O possibly proceeds through addn. of a Br atom, followed by inversion and final loss of the Br atom. If the 2 C atoms of the double bond are alike in properties, both normal and abnormal addn. may take place with either C atom, resulting in approx. equal yields of the isomers. George Ayers

Substituted acetylenes. XXXV. Hydrogenation of substituted acetylenes with Raney nickel. Kenneth N. Campbell and Michael J. O'Connor. *J. Am. Chem. Soc.* **61**, 2897–900 (1939); cf. *C. A.* **33**, 6236[1].—All acetylenes (I) studied are readily reduced with Raney Ni at room temp. and a pressure of 3–4 atm. H; at the beginning, at least, the reaction is markedly exothermic. A relation is shown between the symmetry of the mole and the course of reduction. The reduction curve for monoalkyl derivs. of I showed a slight change in slope at half reduction, whereas the dialkyl derivs. showed a more pronounced change in slope. The Ph and Ph Me derivs. of I showed no change in slope in the reduction curve at half reduction; the Ph_2 deriv. readily adsorbed 1 mole equiv. of H and the reaction stopped with the formation of isostilbene. By stopping the reduction when 1 mole equiv. of H is absorbed it is possible to isolate the corresponding olefin in most cases. When the reduction is carried to completion satd. hydrocarbons are obtained. While the configuration of the olefins was not detd., it is believed to be cis. When H_2PtCl_6 and alkali are used as a promoter, reduction occurs more rapidly in the case of the Am deriv. of I, but there was no significant change in the velocity of reduction of the di-Bu deriv. The following compds. are new: *ethylisoamylacetylene*, b_{97} 92°, n_D^{25} 1.4280, d_4^{20} 0.7599, 35% yield; *Pr analog*, b_{97} 104.5°, n_D^{20} 1.4311, d_4^{20} 0.7681, 35%; *butylamylacetylene*, b_{61} 113°, n_D^{20} 1.4360, d_4^{20} 0.7760, 60%; *4-octene*, b_{746} 127°, n_D^{20} 1.4128, d_4^{20} 0.7184, 66%; *3-nonene*, b_{760} 147.4°, n_D^{20} 1.4173, d_4^{20} 0.7294, 74%; *5-decene*, b_{746} 169.6°, n_D^{20} 1.4249, d_4^{20} 0.7385, 77%; *7-methyl-3-octene*, b_{746} 140.7°, n_D^{20} 1.4168, d_4^{20} 0.7278, 77%; *8-methyl-4-nonene*, b_{746} 163.2°, n_D^{20} 1.4229, d_4^{20} 0.7400, 70%; *5-undecene*, b_{760} 191.2°, n_D^{20} 1.4295, d_4^{20} 0.7516, 86%.
C. J. West

The synthesis of piperylene from furfural. I. A. M. Berkenheim and T. F. Dankova. *J. Gen. Chem.* (U. S. S. R.) **9**, 924–31 (1939).—The synthesis of piperylene (1,3-pentadiene) (I) from furfural has been undertaken with the view to use I as starting material in the manuf. of *synthetic rubber*. To a mixt. of 350 g. tech. furfural, 910 ml. H_2O and 910 ml 40% HCHO, cooled to 5°, there is added 840 g. 50% NaOH soln. within 27–30 min. The temp. is not allowed to rise above 15–20°. After the NaOH soln. has been added the mixt. is heated for 5 hrs. to 40–45° while stirring, then allowed to stand for 16–18 hrs. and finally extd. with ether. Furfuryl alc. (II), b_{18} 81–2°, (yield, 90–1%), is obtained after evapn. of the ether and distn. of the residue *in vacuo*. II (100 g.) in 130 ml. H_2O + 15 ml. alc. is introduced into 1635 ml. 0.5 *N* HCl while boiling for 15–20 min. The reaction mixt. is then cooled rapidly, filtered and evapd. *in vacuo*. Levulinic acid (III) distils at 144–6° and 14 mm. in 62–4% yield. To 30 g. III in 190 g. 10% NaOH 300 g. 4% Na-Hg is added in small portions at 35–40° while stirring. The mixt. is kept overnight and then another portion of 225–30 g. Na-Hg is added under the same conditions. After the reduction is finished the reaction mixt. is sepd. from Hg, filtered, acidified with concd. H_2SO_4 and boiled for 20–30 min. After cooling, the reaction mixt. is extd. repeatedly with ether. The ether soln. is dried, the ether evapd. and the residue distd. γ-Valerolactone (IV), b. 202–4°, is obtained in 81.5% yield. III may also be reduced to IV electrically, the yield of IV being 63–5%. IV (20 g.) in 30 g. abs. alc. is quickly introduced at 60° into a mixt. of 120 g. xylene and 28 g. Na that has been previously heated to 90°. Then 100 ml. abs. alc. is added, stirring is continued until the Na has dissolved, 40 ml. 50% alc. is added and the mixt. is boiled for 15–20 min. Alc. and xylene are eliminated from the mixt. by means of steam. The residue, after cooling, is satd. with potash and the resulting 1,4-pentanediol (V) extd. with ether. V, b. 220–2°, is obtained in 59% yield (based on IV). 1,4-Dibromopentane (21 g.), obtained from V on heating with HBr satd. at 0°, is treated slowly at 175–80° with 21 g. PhNMe$_2$. The reaction product b. 110–20°. The distillate is purified by distn. The bromopentene, b. 127–8°, d^{15} 1.2547, is isolated in 59–60% yield. Monobromopentene (15 g.) is added to 10 g. KOH in 15 g. 90% alc. while stirring and heating. I distils from the reaction mixt. and b. 40.5–1.5°, d_0^0 0.6964, after purification. The yield is 60%. I yields a tetrabromide, m. 114°. The by-product formed is the unsatd. ether C_5H_9OEt, b. 120–3°.
Gertrude Berend

Organic parachors. IV. Constitutive variations of the parachors of a series of tertiary chlorides. Osborne R. Quayle, Katherine Owen and Ellington M. Beavers. *J. Am. Chem. Soc.* **61**, 3107–11 (1939); cf. *C. A.* **33**, 4190[8]. —Values are given for d., γ and *P* at 0–75° for the following compds.: Me_3CCl, Me_2EtCCl, $MeEt_2CCl$, Et_3CCl, Et_2PrCCl, $EtPr_2CCl$, Pr_3CCl, Me_2PrCCl, $MePr_2CCl$, $MeEtPrCCl$, Me_2BuCCl, $Me_2(C_6H_{13})CCl$, $MeEt(C_6H_{13})CCl$, $MePr(C_6H_{13})CCl$, $MeBu(C_6H_{13})CCl$, $MeAm(C_6H_{13})CCl$. *P* shows a decrease with temp. of approx. 0.2% per 10° rise in temp. The effect of substitution in Me_3CCl is of the same order as that with Me_3COH. Values for the individual CH_2 groups in the tertiary chlorides are approx. the same as those obtained for the corresponding CH_2 groups in the tertiary carbinols. The similarity of the values for the chlorides and alcs. indicates that assocn. is not an important factor in the *P* values of the alc. series. The calcd. and observed values for the tertiary branching are in closer agreement than the values previously used. C. J. West

Bromination of hexane. W. Flörke. *Z. physik. chem. Unterricht* **52**, 100–1 (1939).—When Br is added to C_6H_{14} in direct sunlight, in a bright room, or under a 500-w. lamp, bromination occurs. Over a 3-hr. period 170 g. of Br was added to 33 g. of C_6H_{14}. F. E. Brown

The peroxide effect in the addition of reagents to unsaturated compounds. XXI. "Normal" and "abnormal"

additions of hydrogen bromide. M. S. Kharasch, Sarah C. Kleiger and Frank R. Mayo. *J. Org. Chem.* 4, 428–35 (1939); cf. *C. A.* 33, 6791[7].—In the earlier papers of this series, the products formed by addn. of HBr to unsatd. compds. when the reaction is carried out in the absence of O or peroxides (in the presence or absence of an antioxidant) are regarded as "normal" addn. products, while those formed in the presence of O or peroxides are designated "abnormal" addn. compds. The difficulty of designating as "normal" or "abnormal" any given addn. product of HBr to CCl_2:CHCl, MeCH:CHCl or MeCH:CHBr is discussed. The results of the addn. of HCl or HBr to MeCH:CH_2, Me_2C:CH_2, CH_2:$CHCH_2Br$, CH_2:$CHCH_2Cl$, MeCBr:CH_2, $MeCCl$ CH_2, CH_2:CHBr, CCl_2:CHCl, MeCH:CHBr and MeCH:CHCl in the presence of $FeCl_3$ indicate that only the "normal" addn. products are formed and in all cases except the last 3 the addn. products are identical with those obtained in the presence of antioxidants. These must therefore be the "normal" addn. products. $FeCl_3$ greatly accelerates the rate but does not change the "normal" direction of the addn. of HCl or HBr. It appears evident that in such addn. reactions antioxidants and metallic halides are neg. and pos. catalysts, resp., and that their concordant influence upon the direction of addn. is adequately elucidated by the fact that the former retard or suppress the "abnormal" addn. reaction whereas the latter accelerate the "normal" reaction. F. E. Brauns

Peroxide effect in the addition of reagents to unsaturated substances. XXII. The addition of hydrogen bromide to trimethylethylene, styrene, crotonic acid and ethyl crotonate. Cheves Walling, M. S. Kharasch and F. R. Mayo. *J. Am. Chem. Soc.* 61, 2693–6(1939); cf. *C. A.* 33, 6791[7].—Me_2C CHMe adds HBr in the absence of O and peroxides to give *tert*-AmBr; under conditions of peroxide catalysis the product contains as much as 64% of the abnormal product, 2-methyl-3-bromobutane. PhCH CH_2 adds HBr in the absence of O and peroxides to give PhCHBrMe; under conditions of peroxide catalysis and in the presence of solvent the product contains as much as 80% of $PhCH_2CH_2Br$. In the presence or absence of peroxides, crotonic acid and its Et ester yield only β-bromobutyric acid and its Et ester, resp. **XXIII. The reaction of styrene with bisulfite.** M. S. Kharasch, Remsen Ten Eyck Schenck and F. R. Mayo. *Ibid.* 3092–8.—PhCH CH_2 and NH_4HSO_3, O-catalyzed, give $PhCH_2CH_2SO_3H$ (I), PhCH:$CHSO_3H$ (II) and *2-hydroxy-2-phenylethanesulfonic acid* (III). The reaction is dependent upon the pH of the original aq. salt soln.; the addn. occurs under more extreme conditions of acidity and alky. than was formerly believed but such variations are ineffective in causing appreciable changes in the ratio of products formed. Salts of the NH_4 group, including all the alkylammes tested, give somewhat more II at the expense of I than do those of the alkali metals. The rate of the reaction is effectively independent of the salt employed but is closely related to the O concn.; the over-all yield of org. sulfonates shows an inverse relationship to the O tension. Increasing O pressure favors the substitution reaction at the expense of the addn. reaction. Replacement of O by NO_2 or perdisulfate ion results in complete suppression of the substitution reaction, the proportion of both the addn. product and III being at the same time slightly increased. Over-all yields are to some extent influenced by the rate at which the oxidant is introduced but are no better than those from O at 1 atm. pressure. NO_2 was of little value as an oxidant. It is considered that I–III are primary reaction products. The reaction mixt. is evapd. to dryness and extd. with 1 l. of boiling 70% alc. per mole of sulfite consumed; evapn. of the filtrate and extn. with 10 cc. boiling 90% EtOH per g. gives nearly pure III, which may be recrystd. from 70% EtOH. The filtrate contains a mixt. of the Na salts of I and II, which may be purified by crystn. from 85–90% EtOH or better as the Ba salt (of II, with 1 mole of H_2O). The 2 salts cannot be sepd. in an approx. equimol. mixt.; a small amt. of II cannot be sepd. from a mixt. rich in I. Styrene bromo- or iodohydrin and aq.-Na_2SO_3 give III (as the *Na salt*); III is stable to both acid and alk. $KMnO_4$ oxidation in the cold and even at 90–100° the oxidation is relatively slow. *Phenylhydrazinium salt* of III, yellow, m. 180–1° (decompn.). Reaction of III with PCl_5 and refluxing the chloride with satd. aq. Na_2CO_3 give II. The Na salt of II, $NaHSO_3$ and NaOH, shaken with O, give *di-Na 2-phenylethane-1,1-disulfonate*, with 2 moles H_2O; this also results from styrene dibromide and Na_2SO_3; PCl_5 causes extensive decompn.; *phenylhydrazinium salt*, yellow, m. 187–8° (decompn.). A mechanism involving O has been proposed to explain the substitution of bisulfite in styrene and one independent of the nature of the oxidant to account for the formation of the HO deriv. Cf. preceding abstr. C. J. West

Allylic rearrangements. IX. The isolation and rearrangement of primary and secondary pentenyl, hexenyl and heptenyl bromides. Wm. G. Young, Lawrence Richards and Julian Azorlosa. *J. Am. Chem. Soc.* 61, 3070–4(1939); cf. *C. A.* 33, 1693[6].—The bromide mixts. were prepd. by the action of 240 ml. 48% HBr and 24 ml. 95% H_2SO_4 on 1 mole of the carbinol at room temp. for 2 days. They contained 80–90% of the primary bromide (RCH·$CHCH_2Br$), which was readily sepd. by low-temp. fractionation; the secondary bromides (RCHBrCH.CH_2) were isolated by distn. of an accumulation of the proper fraction. In some cases the primary fraction was heated until equil. was established, freed of the primary fraction and used for the secondary fraction. 1-Bromo-2-pentene (I), b_{30} 43.5°, n_D^{25} 1.4777, d_4^{25} 1.2606; 3-bromo-1-pentene (II), b_{30} 30.5°, n_D^{25} 1.4626, d_4^{25} 1.2417; 1-bromo-2-hexene (III), b_9 28°, n_D^{25} 1.4761, d_4^{25} 1.2049; 3-bromo-1-hexene (IV), b_9 22°, n_D^{25} 1.4627, d_4^{25} 1.1849; 1-bromo-2-heptene (V), b_3 32°, n_D^{25} 1.4745; 3-bromo-1-heptene (VI), b_3 23–5°, n_D^{25} 1.4560–1.4590 (contains some heptadiene). Heated in a sealed tube at 100° until no further change in *n* was observed, I and II gave an equil. mixt. with 80.1% I; III and IV, 85.5% of III; V and VI, 89% V (estd.). The *n* method of analysis of such bromide mixts. has been shown to be valid. The rearrangements of these bromides are very sensitive to minute traces of catalytic substances and it is impossible to secure reproducible results for abs. mobilities or rates of rearrangements. Qual. observations at 100° indicate that the order of decreasing mobility is butenyl, hexenyl, pentenyl, heptenyl, resp. Conflicting reports in the literature concerning the compn. of bromides made from the alkylvinylcarbinols are discussed. C. J. West

Dimorphism of normal long-chain alcohols. Ken-iti Higasi and Masazi Kubo. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) 36, 286–300(1939).—Crude cetyl alc. was acetylated. Fractional distn. gave cetyl acetate (I), $b_{1.5}$ 156.8°, and octadecyl acetate (II), $b_{1.5}$ 172.4°. Hydrolysis of I gave cetyl alc., which, purified by 7 recrystns. from MeOH and high vacuum distn., $b_{0.01}$ 125–35°, m. 49.1–49.2°. Saponn. of II, followed by a similar purification of the cleavage product, gave octadecyl alc., $b_{0.9}$ 160°, m. 57.60–7.75°. Thermometric, dilatometric and dielec. const. measurements all indicated cetyl and octadecyl alcs. to be dimorphic. The ax transition temps., detd. by these methods are, for cetyl alc., 42.4°, 44.5°, 44°; for octadecyl alc., 52.8°, 54.5°, 55°, resp. W. Gordon Rose

The isomerization of geranyl acetate. V. I. Isagulyants and G. A. Serebrennikov. *J. Gen. Chem.* (U. S. S. R.) 9, 917–23(1939).—Pure geraniol, b_8 107°, d^{15} 0.8830, n_D^{20} 1.4768 (300 g.) yields, at room temp. on reaction with 300 g. Ac_2O in the presence of a catalyst consisting of 90 parts Ac_2O + 10% H_3PO_4 (d. 1.7), 342 g. pure geranyl acetate (I), b_7 114–15°, d^{15} 0.9160, n_D^{20} 1.4655. I gives cyclogeranyl acetate (II) and terpin hydrate when it reacts with 85% H_3PO_4 at −5° whereas practically no isomerization is observed under the above conditions in the presence of toluene or by using toluenesulfonic acid, an aq. soln. of $ZnCl_2$ and of HCO_2H as catalyzing agents. When 92% H_3PO_4 is used only II is formed. Cyclogeranyl butyrate, b_6 106°, d^{20} 0.9435, n_D^{20} 1.4660, is obtained by adding 12 g. PrCOCl to 10 g. cyclogeraniol and 8 g. pyridine at 0°. Cyclogeranyl caproate, b_4 126°, d^{20} 0.9344, n_D^{20} 1.4662. Cycloger-

aniol, b_4 73°, d^{20} 0.9382, n_D^{20} 1.4843, is obtained from II on sapon. with alc. KOH. Gertrude Berend

The preparation of ethers. Philip G. Stevens and Sidney A. V. Deans. *Can. J. Research* **17B**, 290–2 (1939).—A new modification of Williamson's (*Ann.* **77**, 37–49(1851)) ether synthesis, in which Na naphthalene is used to form the metal alcoholate, is described, by which the yields and ease of prepn. of ethers have been improved. J. W. Shipley

Polysulfones. X. Vinyl chloride polysulfone. C. S. Marvel and L. H. Dunlap. *J. Am. Chem. Soc.* **61**, 2709-10(1939); cf. *C. A.* **33**, 6237³.—Hydrolysis of vinyl chloride polysulfone (I) (*C. A.* **33**, 125⁸) with 20% aq. NaOH gives 6.2% AcH; at the same time all the Cl is removed from the org. mole as NaCl and practically all of the S remains in org. combination. This leads to the structure $-(SO_2CHClCH_2CHClCH_2)_n-$ for I. The pyrolysis of I in dioxane is a very complex reaction, SO_2 and HCl being lost. Liquid NH_3 removes the Cl from I, forming NH_4Cl; considerable SO_2 is also removed; definite polymeric products could not be isolated from the reaction mixt.

XI. The compound $C_{10}H_{16}SO_2$ from 1-pentyne polysulfone and some experiments on other acetylene polysulfones. C. S. Marvel and W. W. Williams. *Ibid.* 2710-14.—Pyrolysis of 1-pentyne polysulfone (I) (M. and Ryder, *C. A.* **30**, 8184⁹) in dioxane proceeds to some equil. stage; if unchanged I is isolated and pyrolysis in fresh dioxane is repeated, there finally results 22% of the compd. $C_{10}H_{16}SO_2$ (II). Other cryst. compds. have not been isolated from I and it has not been possible to obtain a similar product from other acetylene polysulfones. That II has an α,β-unsatd. sulfone linkage follows from its addn. of $CHNa(CO_2Et)_2$, which gives the *compd.* $C_{17}H_{28}O_6S$, m. 104.5–5°. II does not add Br but decolorizes alk. $KMnO_4$. II is considered to be a dipropylthiophene oxide. Reduction of II with Zn and AcOH gives a *dihydro deriv.*, m. 49–50°; this reaction must proceed by a 1,4-addn. of II with a resulting shift of the double union to the 3,4-position in the ring as otherwise this reduction would be expected to give a tetrahydro deriv. Catalytic reduction of II gives a 2nd *dihydro deriv.*, m. 56.5 7°; this must be the 1,2-addn. product, although it could not be further reduced with Zn and AcOH. I is not reduced by Zn in AcOH (boiling 13 hrs.), by H with PtO_2-Pt black catalyst, and did not add $CHNa(CO_2Et)_2$ in the cold (degradation on warming); EtMgBr gives amber to red solns. with evolution of gas; recovery of I showed that considerable degradation had taken place. Other polysulfones behaved similarly. X-ray diffraction diagrams are given for I and the hexyne, heptyne, nonyne and pentadecyne polysulfones. Attempts to prep. acetylene polysulfone were not successful.

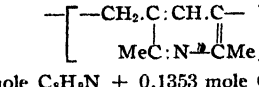
XII. Synthesis of 3,4- and 2,5-dipropyltetrahydrothiophene 1,1-dioxides. *Ibid.* 2714–16.—The syntheses of III and IV were carried out to have reference compds. in the study of the pyrolysis compd. discussed in Part XI. $PrCH(CO_2Et)_2$, $PrCHBrCO_2Et$ and Na in EtOH, heated 15 hrs., give 59% of *4,4,5-tricarbethoxyoctane*, b_1 182-3°, d_{20}^{20} 1.0170, n_D^{20} 1.4393; hydrolysis with 40% aq. KOH (refluxing overnight), acidification with HCl at 0° and warming to room temp. give a nearly quant. yield of α,α'-dipropylsuccinic acid (cis form, m. 115–17°; trans form not isolated pure); EtOH-H_2SO_4 gives the mixed *di-Et ester*, b_1 86-7°, d_{20}^{20} 0.9568, n_D^{20} 1.4302. Catalytic reduction (Cu-Cr oxide) of 70.7 g. of the ester in dioxane under 300 atm. pressure at 260° (20 hrs.) gives 54.2% of *3,4-dipropyltetrahydrofuran* (I), b_1 40-2°, d_{20}^{20} 0.8683, n_D^{20} 1.4369, and a small amt. of *2,3-dipropylbutane-1,4-diol*, b_1 103°, d_{20}^{20} 0.9378, n_D^{20} 1.4563. I and HBr in AcOH (satisfactory conditions not developed) give *1,4-dibromo-2,3-dipropylbutane* (II), b_1 95°, d_{20}^{20} 1.3834, n_D^{20} 1.4971; with EtOH-Na_2S (II added during 1 hr. and boiled an addnl. 10 hrs.) there results 77.5% of *3,4-dipropyltetrahydrothiophene*, b_1 65–6°, d_{20}^{20} 0.9129, n_D^{20} 1.4830; this is oxidized by H_2O_2 in AcOH (heating on steam bath for 2 hrs.) to the *1,1-dioxide* (III), m. 57–9.5°. (i-PrMgBr)₂ and PrCHO give 41.8% of *5-decyne-4,7-diol*, b_1 113–14°, d_4^{20} 0.9462, n_D^{20} 1.4678; catalytic reduction gives 71% of 4,7-decanediol, m. 79–80°; passing dry HBr through the glycol for 4 hrs. at 45–60° and for 18 hrs. at 105–15° gives 85.3% of *4,7-dibromodecane*, b_1 106–9°, d_4^{20} 1.3354, n_D^{20} 1.4920; Na_2S gives 77% of *2,5-dipropyltetrahydrothiophene*, b_1 74–5°, d_4^{20} 0.8958, n_D^{20} 1.4795; *1,1-dioxide* (IV), b_1 123–5°, d_4^{2} 1.0408, n_D^{20} 1.4719. The refractive const. for the SO_2 group is calcd. to be 8.7. C. J. West

Formation of bis(β-diethylaminoethyl) sulfide. Elton S. Cook and Cornelius W. Kreke. *J. Am. Chem. Soc.* **61**, 2971–2(1939).—Heating 150 g. $Na_2S.9H_2O$ at 130° for 15 min., satg. with H_2S, cooling to 60–5° with continued passage of H_2S, adding 10.2 g. of $BrCH_2CH_2NEt_2$.HBr with stirring, maintaining the temp. at 55° for 15 min., cooling, extg. with 3 portions of 100 cc. of Et_2O, drying the oily residue and satg. with HCl give 2.12 g (36%) of $(Et_2NCH_2CH_2)_2S.2HCl$, m. 245.5–7.5° (cor.); the *di-HBr salt* m. 237.3–7.8° (cor.). C. J. West

Utilization of aliphatic nitro compounds. I. Production of amines. II. Production of oximes. Kenneth Johnson and Ed. F. Degering. *J. Am. Chem. Soc.* **61**, 3194–5 (1939).—All the nitroparaffins available from the nitration of propane, butane and isobutane have been reduced to the corresponding amines by the use of Fe and HCl or by catalytic hydrogenation (92–8%). These processes produce easily purified products and require only simple technique. The results indicate that primary, secondary and tertiary nitroparaffins can be reduced to give almost quant. yields of the corresponding amines. Nitroparaffins may be reduced to oximes by refluxing with Zn in AcOH (6 hrs. with 1-nitropropane); hydrolyzing with dil. H_2SO_4 gives the aldehyde, the yield of which is 43%. C. J. West

Alkylation of α-sulfonylamides. Austin Pomerantz and Ralph Connor. *J. Am. Chem. Soc.* **61**, 3139-45 (1939); cf. *C. A* **32**, 1672³.—The alkylation in alc. of α-alkanesulfonylamides is complicated by the fact that the compds. are not acidic enough to form Na derivs. satisfactorily in the presence of a considerable amt. of alc. In inert solvents alkyl halides are not very reactive but Et_2SO_4 reacts readily with the Na deriv. of I. $BuSO_2CH_2CONH_2$ (I) and EtBr with EtONa gives 11% of $BuSO_2CHEtCONH_2$ (II), with the recovery of 20% of I. I and BuBr with EtONa in EtOH give 15% III. Refluxing the Na deriv. of I and EtI in C_6H_6 for 55 hrs. gives 33% II; BuBr in PhMe, refluxed 25 hrs., gives 19% of *α-butanesulfonylcaproamide* (III), m. 110.5 11°; reaction with $AgNO_3$ indicated 56% reaction. *α-p-Toluenesulfonylcaproamide*, m. 165.5°, results in 25% yield from *p*-$MeC_6H_4SO_2CH_2CONH_2$ and BuBr in PhMe (19 hrs.); $PhCH_2Cl$ in PhMe (18 hrs.) gives 44% of *α-benzyl-α-p-toluenesulfonylacetamide*, m. 203–4°. The Na deriv. of I and Et_2SO_4 in PhMe, refluxed 7 hrs., give 30% of II; 7% of $BuSO_2CH_2CONHEt$ (III) and 0.4% of $BuSO_2CHEtCONHEt$ (IV); the remainder was probably a mixt. of III and IV. Refluxing 31 g. III and EtONa in PhMe for 2.5 hrs., adding 28.2 g. Et_2SO_4 and refluxing for an addnl. 2.5 hrs. gives 47% IV; likewise II gives 47% IV. $BuSCH_2CONH_2$ (V), as the Na salt, and Et_2SO_4 probably give $BuSCH_2CONHEt$, which is oxidized by H_2O_2 to III. I is recovered to the extent of 84% after refluxing with EtONa in C_6H_6 for 2.5 hrs.; V is recovered to the extent of 69%. V is prepd. in 90% yield from $ClCH_2CO_2Na$ and BuSNa; oxidation with H_2O_2 in 1.1 Ac_2O-AcOH in the cold and then at room temp. gives 77% of *α-butanesulfonylacetic acid*, m. 67.5–8.5°; reaction with $SOCl_2$ and then with $EtNH_2$ gives 53% of *α-butanesulfonyl-N-ethylacetamide*, (III), m. 73–3.5°. The m. ps. are cor. The results may be interpreted as evidence that in the system $-CH_2.CO.NH_2$ of this series, 2 types of Na derivs. are formed and that the $-CH_2-$ and $-NH_2$ groups are activated to about the same extent. Introduction of an alkyl substituent on either $-CH_2-$ or $-NH_2$ decreases the relative reactivity of the group to which the alkyl substituent is attached and subsequently alkylation occurs on the other active group. C. J. West

Silicoörganic compounds. I. The preparation of silicon analogs of certain aliphatic ortho esters. Howard W. Post and Charles H. Hofrichter, Jr. *J. Org. Chem.* **4**, 363–4(1939).—Some aliphatic *orthosilicopropionates* (I),



-butyrates (II) and *-benzoates* (III) are prepd. *Et* I (IV), prepd. according to Andrianov and Gribanova (*C. A.* **32**, 7892[8]) in 83.7% yield, b. 158–60°, d_4^{22} 0.928, n_D^{22} 1.3853; *Pr* I, prepd. by refluxing IV with PrOH, b. 202–4°, d_4^{23} 0.896, n_D^{23} 1.4017, n_D^{19} 1.4060; *Bu* I, b. 235–8°, d_4^{24} 0.878, n_D^{24} 1.428, n_D^{19} 1.4174; *Am* I, b. 285°, d_4^{23} 0.891, n_D^{23} 1.4210, n_D^{19} 1.4262; *iso-Am* I, b. 266–9°, d_4^{24} 0.891, n_D^{24} 1.4170, n_D^{19} 1.4222; *Et* II, prepd. from $Si(OEt)_4$ (V) and PrMgBr, b. 179–80°, n_D^{19} 1.4076, d_4^{26} 0.852; *Et* III, prepd. from V and PhMgBr, b.$_{4}$ 235–8°, d_4^{19} 1.0055; *Pr* III, obtained by treating $PhSiCl_3$ with PrOH, b$_7$ 192°, d_4^{20} 1.036, n_D^{19} 1.5025; $Si(OC_7H_{15})_4$, prepd. by refluxing $SiCl_4$ with $C_7H_{15}OH$ in 53.5% yield, b$_4$ 213.5°, n_D^{25} 1.4300, d_4^{25} 0.876.

Redistribution reaction. I. The random intermolecular exchange of organic radicals. Geo. Calingaert and Harold A. Beatty. *J. Am. Chem. Soc.* **61**, 2748–54(1939). —A hitherto unrecognized type of reaction is described, in which all the radicals or atoms of 1 kind, present in a mixt. in which they are linked to 1 or more central groups or atoms of another kind, are interchanged between all the central groups present. This process, which is termed the *redistribution reaction*, takes place smoothly at low temps. in the liquid phase under the influence of a catalyst. The yield is quant. and the compn. of the resultant mixt. can be calcd. from that of the reactants on the basis of a random distribution of the interchanged radicals or atoms: this reaction product is therefore termed a *random equil. mixt.* The reaction presents interesting possibilities for theoretical investigation into the nature and behavior of covalent bonds and the mechanism and kinetics of their reactions; also, the reaction provides novel methods of prepn. of various org. compds. The following topics are discussed: exchange of radicals in organometallic halides, equil. interchange of radicals in metal alkyls, characteristics of the reaction, random distribution (application of the laws of probability), exptl. confirmation of random equil. mixts. **II. The analysis of metal alkyl mixtures and the confirmation of random distribution.** Geo. Calingaert, Harold A. Beatty and Herbert R. Neal. *Ibid.* 2755–8.—This paper describes the anal. method used for volatile metal alkyls, including a test of its accuracy and gives a quant. demonstration of random distribution. With known mixts. of Me_4Pb, Me_3EtPb, Me_2Et_2Pb, $MeEt_3Pb$ and Et_4Pb, the standard deviation between the taken and observed values for a group of 10 values was 0.6% and the max. deviation was 0.7%. The proportion of the alkyls present in a given mixt. is detd. by fractional vacuum distn. after removal of the catalyst and halide salts (if any) by filtration and washing or extn.; the distn. equipment and method are described and illustrated. With r for the mole fraction of Me and $1-r$ as that of the Et radical, the predicted mole fractions are Me_4Pb r^4, Me_3EtPb $4r^3(1-r)$, Me_2Et_2Pb $6r^2(1-r)^2$, $MeEt_3Pb$ $4r(1-r)^3$, Et_4Pb $(1-r)^4$. The differences found are scattered at random and do not appear to be a function of the compds., of their concn. or of r. Large effects result from a change in the relative proportions of Me and Et radicals. Data are given for Me_4Sn + Et_4Sn, $C_2H_4Cl_2$ + $C_2H_4Br_2$, Et_4Si + Pr_4Si, Me_2Hg + Et_2Hg and AcOMe + $PrCO_2Et$. In these systems the deviations appear to be well scattered and random and show no significant trends. Vapor pressures of Pb alkyls, $\log_{10} P(\text{mm. Hg}) = A - B/(t+230)$, A, B and t at 50 mm. being given: Me_4Pb 6.9381, 1378.7, 33.2°; Me_3EtPb 7.2760, 1602.5, 57.3°; Me_2Et_2Pb 7.5903, 1810.7, 77.4°; $MeEt_3Pb$ 7.8768, 2000.5, 93.8°; Et_4Pb 8.1547, 2184.6, 108.4°. **III. Determination of a material balance.** Geo. Calingaert and Harold Soroos. *Ibid.* 2758–60.—By detn. of an accurate material balance, the redistribution of a mixt. of Me_4Pb and Et_4Pb in hexane is shown to be quant. The recovery is 98.5%; the remaining 1.5% is R_3PbCl; a trace of $PbCl_2$ is formed (decompn. of R_3PbCl); no Pb is formed. When $AlCl_3$ is used as the catalyst, it is found to react irreversibly with the Pb compds., forming alkyl lead compds. in very small quantities, equiv. to about 1.5 moles per mole of catalyst. Me_2AlCl or $MeAlCl_2$ give values of 0.04 and 0.10 mole of Pb chlorides per mole of catalyst. The results show that the redistribution reaction is quant., apart from such irreversible interaction with the catalyst as may be imposed by the selection of 1 particular catalyst or another. C. J. West

Reaction of organic hydroxy and oxo compounds with ammonia. I. Comparative reaction velocities of ketones with liquid ammonia. S. S. Dragunov. *J. Gen. Chem.* (U. S. S. R.) **9**, 693–7(1939).—The reaction velocity of various oxo compds., such as Me_2CO, MeCOPr, MeCOPh, 3- and 4-methylcyclohexanones and BzH with liquid NH_3 was investigated. When the duration of reaction was prolonged and when the temp. was raised, compds. with higher N content were obtained. Hexaphenylmethane and triphenylmethyl in benzene did not react with gaseous NH_3. Gertrude Berend

Structure of vinyl polymers. IV. The polymers of the methyl α-haloacrylates. C. S. Marvel and John C. Cowan. *J. Am. Chem. Soc.* **61**, 3156–60(1939); cf. *C. A.* **33**, 6797[2].—Me α,β-dibromopropionate and quinoline give 82% of *Me α-bromoacrylate* (I), b_{78} 72.5–4°, d_{20}^{20} 1.61, n_D^{20} 1.4840; Me α-chloroacrylate (II), b_{55} 57.9°, d_4^{20} 1.189, n_D^{20} 1.4400, 73% yield. Diethylglutaric acid, reacted with $SOCl_2$ for 25 hrs., treated with Br (heating at 70° for 5 hrs.), poured into abs. EtOH and distd., gives 48% of the *Br lactone*, b_3 134–8°, d_{20}^{20} 1.358, n_D^{20} 1.4775; satn. with HBr in abs. EtOH gives *Et α,α'-dibromo-α,α'-diethylglutarate* (III). I on standing at room temp. for 3 weeks gives a clear, pale amber, brittle solid; I (20 g.) in 100 g. dry dioxane and 0.48 g. Bz_2O_2, warmed at 35° for 48 hrs., Bz_2O_2 again added, the mixt. allowed to stand an addnl. 48 hrs. and poured into 500 cc. Et_2O, give 15 g. of a polymer (IV). II gives a similar polymer (V) (3 g. from 10 g. II). Both polymers are sol. in Me_2CO and dioxane. Viscosity measurements on 0.606% (0.0368 *M*, based on monomeric unit) solns. indicated a mol. wt. of about 11,500. IV or V, treated with KI in peroxide-free Me_2CO or dioxane, liberates I. This reaction is characteristic for 1,2-dihalo compds. and indicates that IV and V have the structure $-[-CH_2CX(CO_2R)CX(CO_2R)CH_2-]_n$. A comparison is given of the amt. of I liberated from KI by $(CHBrCO_2Et)_2$ (VI), $CH_2(CHBrCO_2Et)_2$ (VII), III and IV. Evidence to support the "head to head, tail to tail" formulation of these polymers was obtained by the use of Zn; this reagent readily removed 97% of the Br from IV, an amt. far above that which could be removed from a 1,3-di-Br polymer; the debrominated polymer decolorizes aq. $KMnO_4$ in 4 hrs. Addnl. evidence supporting the 1,2-dihalo structure of IV is found in a comparison of the effect of heat on IV, VI and III. IV and VI lost HBr at a much lower temp. (110–50° for IV and 130–70° for VI) than did III (175–200°); V on heating at 330°/3 mm. for 1 hr. gives a Cl-free product. Heating IV with quinoline removes half of the Br as HBr. The structure is further supported by the ultraviolet absorption spectra of IV, VI and VII. Hydrolysis of IV with aq. NaOH yields the Na salt of a 1,2-di-HO dibasic acid, which reduces HIO_4 to HIO_3 in approx. 48 hrs. (characteristic of 1,2-glycols); the amt. and rate of oxidation varied with different samples of the polymers but in every test some oxidation occurred. **V. Some reactions of the polymer of methyl vinyl ketone.** C. S. Marvel and Charles L. Levesque. *Ibid.* 3234.—The oxime (3.2 g.) of the polymer (I) of Me vinyl ketone in 50 cc. concd. HCl and 135 g. HCl in 500 cc. EtOH, heated to boiling, 40 cc. H_2O added to complete soln. and refluxing for 19 hrs., gives 2 g. of the polypyridine

(0.4323 mole C_8H_9N + 0.1353 mole C_4H_6O). I (2.8 g.) in dioxane and NaOCl, mixed at 0° and stirred at room temp. for 6 hrs., the aq. layer concd. and acidified with concd. HCl, give 1.15 g. of the brown polyacid, $-[-CH_2-CH(CO_2H)CH_2CH(CO_2H)-]_n-$; analysis indicated that about 90% of the Me ketone groups were oxidized.
C. J. West

Intramolecular oxidation of linoleic acid. Mario Brambilla. *Ann. chim. applicata* 29, 303–14(1939); cf. *C. A.* **33**, 9683⁶.—When linoleic acid is heated 3 hrs. at 320–5° in an inert atm. (N), intramol. oxidation takes place with formation of propionic, butyric, caproic and glutaric acids, water, CO_2, certain acids recognized as sebacic acids, an unsaponifiable portion contg. ethylenic hydrocarbons and a tarry residue. This behavior is similar to that found when oleic acid is heated.
A. W. Contieri

Esters of aliphatic thio acids of high molecular weight. A. W. Ralston, E. W. Segebrecht and S. T. Bauer. *J. Org. Chem.* **4**, 502–5(1939).—A review of the previous work on the prepn. of thio esters shows that this has been confined to thio esters of aromatic acids and of aliphatic acids of low mol. wt. and some doubt arises as to whether the esters of higher aliphatic acids are stable. To check this, some esters of each of the following acids, thiolauric, thiomyristic, thiopalmitic, thiostearic, and thioöleic, are prepd. by the interaction of the acid chlorides and the resp. mercaptans. The acid chlorides are obtained from the acids and SO_2Cl_2 in 80% yield. The Me esters are prepd. in the following way: to a mixt. of 0.1 mol. Bu_3N and 0.12 mol. MeSH cooled to −30°, 0.1 mol. acid chloride is added, drop by drop, over a period of 0.5 hr. The mixt. is then kept at −15° for 12 hrs., then at 4° for 23 hrs. and at room temp. for another 24 hrs. It is then dissolved in Et_2O, washed with H_2O until neutral to litmus, dried and distd. *in vacuo*. The other esters are prepd. by mixing 1.1 mols mercaptan and 0.1 mol. acid chloride at 0° until the evolution of HCl has ceased, the mixt. is slowly heated to 50°, kept for 1 hr. at this temp. and then heated for 0.5 hr. at 80°. The ester is isolated as before. *Thiolaurates.*—*Me*, b_1 112–15°, n_D^{25} 1.4642, n_D^{60} 1.4496, d^{60} 0.8734; *Et*, b_1 115–17°, n_D^{25} 1.4626, n_D^{60} 1.4478, d^{60} 0.8645; *Pr*, b_1 126–8°, n_D^{25} 1.4628, n_D^{60} 1.4478, d^{60} 0.8610; *Bu*, b_1 133–5°, n_D^{25} 1.4640, n_D^{60} 1.4493, d^{60} 0.8595. *Thiomyristates.*—*Me*, m. 34–5°, n_D^{60} 1.4507, d^{60} 0.8668; *Et*, b_1 134–6°, n_D^{25} 1.4632, n_D^{60} 1.4488, d^{60} 0.8609; *Pr*, b_1 148–50°, n_D^{25} 1.4627, n_D^{60} 1.4485, d^{60} 0.8568; *Bu*, b_1 149–51°, n_D^{25} 1.4642, n_D^{60} 1.4501, d^{60} 0.8570. *Thiopalmitates.*—*Me*, m. 44–5°, n_D^{60} 1.4521, d^{60} 0.8644; *Et*, b_1 172–5°, n_D^{25} 1.4648, n_D^{60} 1.4513, d^{60} 0.8547; *Pr*, m. 27–8°, n_D^{25} 1.4642, n_D^{60} 1.407, d^{60} 8559; *Bu*, m. 29–30°, n_D^{25} 1.4646, n_D^{60} 1.4505, d^{60} 0.8579. *Thiostearates.*—*Me*, m. 50–1°, n_D^{60} 1.4526, d^{60} 0.8624; *Et*, m. 38–9°, n_D^{60} 1.4514, d^{60} 0.8550; *Pr*, m. 34–5.5°, n_D^{60} 1.4509, d^{60} 0.8508; *Bu*, m. 31–2°, n_D^{60} 1.4529, d^{60} 0.8534; *Pr thiooleate* b_1 175–8°, n_D^{25} 1.4713, n_D^{60} 1.4577, d^{60} 0.8643. These esters are stable and boil *in vacuo* without decompn.
F. E. Brauns

Loss of optical activity in the reaction of the optically active *erythro*- and *threo*-3-bromo-2-butanols with hydrobromic acid. S. Winstein and H. J. Lucas. *J. Am. Chem. Soc.* **61**, 2845–8(1939); cf. *C. A.* **33**, 6241⁶.—There is complete loss of optical activity when active *erythro*- or *threo*-3-bromo-2-butanol is converted to 2,3-dibromobutane. This confirms the mechanism previously proposed in connection with the conversion of *dl*-*erythro*- and *dl*-*threo*-3-bromo-2-butanol to *meso*- and *dl*-2,3-dibromobutane, resp. The mechanism consists of the production of a butylenebromonium ion, and the subsequent reaction of this ion with bromide ion, 2 inversions occurring in the transformation. Other possible mechanisms for the transformation of bromohydrin to dibromide are discussed and rejected.
C. J. West

Reaction of olefin oxides and sulfur monochloride. M. S. Malinovskiĭ. *J. Gen. Chem.* (U. S. S. R.) **9**, 832–9(1939).—Ethylene oxide (I) and S_2Cl_2 react with the formation of $ClCH_2CH_2Cl$, $MeCHCl_2$, CH_2ClCHO, $HOCH_2CH_2Cl$, and 63.9% $(CH_2ClCH_2O)_2SO$ (based on I); propylene oxide (II) and S_2Cl_2 with the formation of MeCH(OH)CH_2ClCH_2Cl, $MeCHClCHO$ and 41.3% $(CH_3CHClCH_2O)_2SO$ (based on II); and epichlorohydrin and S_2Cl_2 with the formation of 33% $(CH_2Cl)_2CO$ and 67% $(CH_2Cl)_2CHOH$.
Gertrude Berend

Preparation and cyclization of monoacylethylenediamines. II. Samuel R. Aspinall. *J. Am. Chem. Soc.* **61**, 3195–7(1939); cf. *C. A.* **33**, 4210⁴.—An ester (RCO_2Et) may be converted into the corresponding 4,5-dihydroimidazole in an over-all yield of about 75% when R is Me, Et, Am, Et_2CH, $(iso\text{-}Am)_2CH$, Ph, *p*-MeC_6H_4 or $PhCH_2$. The procedure is illustrated by the following: 48 g. Et_2CHCO_2Et and 60 g. $C_2H_4(NH_2)_2$ are heated at 215° for 24 hrs. and the low-boiling material is removed by distn.; the mixt. of 39 g. of mono- and diamide is heated with 94 g. of CaO at 225° for 15 hr. in N atm.; the *2-diethylmethyl-4,5-dihydroimidazole* (I) is extd. with alc., distd. and crystd. from petr. ether. Caproylethylenediamine (II), 80% yield; *picrate*, m. 93° (all m. ps. cor.); *HCl salt*, m. 141°; *phenylurea*, m. 171°; when it is distd. the temp. falls from 135° (probably the b. p. of II) to 108° (both at 7 mm.), the b. p. of 2-amyl-4,5-dihydroimidazole (picrate, m. 127°). *Diethylacetyl analog* of II, b_7 113°, 60% yield; *picrate*, m. 123°; *HCl salt*, m. 133°; *phenylurea*, m. 179° (this apparently exists in dimorphic forms, 1 form m. at any temp. between 150 and 179°). I m. 86°, b_9 97°, 70%; *picrate*, m. 106°; *HCl salt*, m. 245°; *phenylurea*, m. 133°. *Diisoamylmethyl analog* of I, b_6 123°, m. 103°; *picrate*, m. 125°; *phenylurea*, m. 82°. *Phenylacetyl analog* of II forms a *picrate*, m. 133°; *HCl salt*, m. 142°; *phenylurea*, m. 191°. *Phenylmethyl analog* of I, b_6 134°, m. 68°, 75% yield; *picrate*, m. 149°; *HCl salt*, m. 174°. *Diphenylmethyl analog* of I, m. 137°, 35% yield; *picrate*, m. 185°. A study is reported of the ease of dehydration of monoacylethylenediamines.
C. J. West

Alkanolamines. VII. Condensation products of monoethanolamine and the isomeric dichloronitrobenzenes. Chester B. Kremer and Aaron Bendich. *J. Am. Chem. Soc.* **61**, 2658–61(1939); cf. *C. A.* **33**, 6259².—Details are given of the prepn. of 3,5-, 2,6-, 2,4- and 2,3-$Cl_2C_6H_3NO_2$. Reaction of the $Cl_2C_6H_3NO_2$ with $HOC_2H_4NH_2$ was carried out in a solvent, usually BuOH, in some cases using MgO as an acid binder. Reduction of the NO_2 compds. was carried out with $Na_2S_2O_4$ in a weakly alk. soln. The following *2-anilinoethanols* were prepd.: *6-chloro-2-nitro*, b_2 155–7°; *5-chloro-2-nitro*, m. 116° (m. ps. cor.); *4-chloro-2-nitro*, m. 107.5°; *3-chloro-2-nitro*, m. 78.5°; *6-chloro-4-nitro*, m. 120°; the yields are 60, 88, 70, 13 and 64%, resp.; *6-chloro-2-amino*, b_2 135–7°; *5-chloro-2-amino*, m. 104.5°, 90%; *4-chloro-2-amino*, m. 122.5°, 90%; *3-chloro-2-amino*, m. 74°, 85%; *6-chloro-4-amino*, decomps. at 185°/1 mm. 3,4- and 2,4-$Cl_2C_6H_3NO_2$ give the same product, showing that the Cl atom ortho to the NO_2 group is mobile. The 2,6-di-Cl deriv. is the least reactive; the 2,5-di-Cl deriv. is more reactive than the 3,4-compd.
C. J. West

X-ray and thermal examination of the glycerides. VII. Unsymmetrical mixed triglycerides, $CH_2(OCOR)CH(OCOR)CH_2(OCOR')$. M. G. R. Carter and T. Malkin. *J. Chem. Soc.* 1939, 1518–21; cf. *C. A.* **33**, 7732⁴.—M. ps. for the vitreous, α-, β′- and β-forms are reported as follows: *α-decodimyristin* 15, 32, 38, 43.5°; α-laurodipalmitin 32, 45, 49.5, 54°; α-myristodistearin 44, 54, 57.5, 62°; *α-myristodidecoin* 3, 20, 31, 34.5°; α-palmitodilaurin 20, 33, 43, 46.5°; *α-stearodimyristin* 36, 46, 43, 46.5°; α-decodipalmitin 23, 37, 41, 45.5°; α-laurodistearin 36, 47, 52°, —; *α-palmilodidecoin* 2, 24, 32, 35°; α-stearodilaurin 20, 31, 32, 35°; *α-stearodidecoin* 13, 32, 38, 41°; α-decodistearin 33, 42.5, 46, 49°. The poor cryst. appearance of unsym. compared with sym. ones is most marked and should afford a valuable clue of identity in compds. from natural products. M. ps. of many of these derivs. are so close to those of their sym. isomers that differentiation between pairs of isomers by m. ps. alone would be almost impossible; the 2 types are readily distinguished by their x-ray data. The x-ray data for long and side spacings are given. The majority of the long spacings of β-forms are too large to correspond with layers of single mols. but smaller than would be expected from layers of double mols. The regularities in m. p. and x-ray data and the small increase in length per C atom on passing up any particular group favor the view that tilt of the mol. is mainly responsible. Side spacings are of the normal type. All the glycerides exhibit typical spherulite formation.
C. J. West

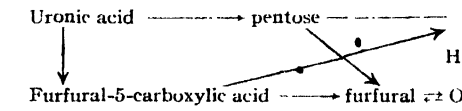
Synthetic glycerides of unsaturated fat acids. I. Mono- and trilinolein. Howard C. Black and Charles A. Overley. *J. Am. Chem. Soc.* **61**, 3051-2(1939).—9,10,-12,13-Tetrabromostearic acid (80 g.) at 120°, treated with 15 g. of $SOCl_2$ during 1 hr., gives 78 g. of the *chloride* (I), m. 59.5–60°; addn. of 45 g. of I in 20 ml. $CHCl_3$ to a cold soln. of 10 g. of acetoneglycerol and 9.6 g. of quinoline and allowing to stand 48 hrs. gives 35 g. of the condensation product, m. 51-2°; concd. HCl in Et_2O in an ice bath gives 26 g. of *mono(9,10,12,13-tetrabromo)stearin* (II), m. 101.5-20°; reaction of 45 g. of I and 2.2 g. of $C_3H_5(OH)_3$ in quinoline gives 30.5 g. of *tri(9,10,12,13-tetrabromo)stearin* (III), m. 81–1.5°. Debromination of 20 g. of II with Zn and EtOH gives 8.9 g. of monolinolein (IV), m. 14–15°, n_D^{25} 1.4758; III gives trilinolein (V), m. −5 to −4°, n_D^{25} 1.4709. With 0.4 *N* $EtOH$-HCl some Et linoleate was formed. IV and Br give 40–5% of II and some oily material. No homogeneous product could be isolated from the reaction of V and Br. C. J. West

Acetylene chlorohydrins and the corresponding dioxides and erythritols. N. A. Hershtein. *J. Gen. Chem.* (U. S. S. R.) **9**, 361-8(1939).—($BrMgC{:}$)$_2$ in Et_2O with $ClCH_2OMe$ in an atm. of N or acetylene gave *dichlorotetramethylbutynediol* (I), viscous yellow oil, which could not be purified. I in Et_2O with powd. KOH, added in small portions, gave 2 stereoisomeric forms of the *oxide* $C_8H_{10}O_2$; *cryst. form* (II), m. 44.5–5.0°; *liquid form* (III), b_{12} 95–6°, b_{18} 104.5–5.0°, d_4^{20} 1.0022, n_D^{25} 1.4065, M. R. 36.73 (calcd. 36.03). Isomerization of II and III with $ZnCl_2$ proceeded with explosive force to give a polymeric product, not purified, which gave pos. aldehyde tests. III oxidized with 1 2% $KMnO_4$ at 5° or with 3–5% O_2 in $CHCl_3$-H_2O gave α-methylglyceric acid (IV), m. 99.5°, isolated as the K salt. II with O_3 also gave IV. The hydration of II in the presence of traces of HCl gave *2,5-dimethyl-3-hexene-1,2,5,6-tetraol* (*acetylene erythritol*) (V), m. 113.5–4.0°, which with Ac_2O gave the *tetra-Ac deriv.*, $C_{16}H_{22}O_8$, b_6 171°. III underwent hydration with greater difficulty to give the stereoisomer of V, m. 130–1°; *tetra-Ac deriv.*, b_9 193–4°. An attempt to hydrate V in the presence of Hg salts gave a glassy mass, insol. in org. solvents, probably a mixt. of condensation products.

John Livak

Oxidation of 1,2-glycols or 1,2,3-polyalcohols by means of lead tetraacetate in aqueous solution. Erich Baer, J. M. Grosheintz and Hermann O. L. Fischer. *J. Am. Chem. Soc.* **61**, 2697-9(1939).—Oxidation with $Pb(OAc)_4$ can be carried out quantitatively in aq. soln. and in H_2O-contg. solvents; this observation enlarges the field of its application. The same oxidation products are obtained in H_2O as in org. solvents, except in rare cases where secondary hydrolysis products may be formed. $Pb(OAc)_4$ (4.43 g.) in 25 cc. glacial AcOH, added to 2.6 g. of 1,2,5,6-diacetone-*d*-mannitol in 60 cc. H_2O, causes instantaneous oxidation to acetone-*d*-glyceraldehyde, hydrolyzed quickly to *d*-glyceraldehyde (I) and Me_2CO (98.8% yield). Similarly pinacol gives 95% of Me_2CO. Me quinate gives a nearly quant. yield of the dialdehyde (II) and HCO_2H, with 2 moles $Pb(OAc)_4$. II can be oxidized by Br to citric acid (86% yield). Oxidation of I with Br gives 76% of glyceric acid (III), characterized as the Me ester and the Ca salt. The above procedure is a convenient method for prepg. III. C. J. West

Acetylation of lactic esters by ketene. H. V. Claborn and Lee T. Smith. *J. Am. Chem. Soc.* **61**, 2727-8(1939). —The esters of lactic acid can be acetylated with ketene in the presence of a trace of H_2SO_4 as catalyst, the yields being practically quant. *Pr α-aceloxypropionate*, b_7 77–9°, b_{763} 196°, d_{25}^{25} 1.0163, n_D^{25} 1.4123, 97% yield with ketene, 87% with Ac_2O; *iso-Bu ester*, b_9 90–2°, b_{763} 205°, d_{25}^{25} 0.9952, n_D^{25} 1.4140, 94, 87% yields; *iso-Pr ester*, b_8 74–8°, b_{763} 183°, d_{25}^{25} 0.9920, n_D^{25} 1.4069, 96.5 and 86% yields; *Am ester*, b_9 101–3°, b_{763} 227°, d_{25}^{25} 0.9822, n_D^{25} 1.4199, 97 and 87% yields; *iso-Am ester*, b_{12} 107–10° b_{763} 222°, d_{25}^{25} 0.9838, n_D^{25} 1.4190, 96, 90% yields; *benzyl ester*, b_7 145–8°, 96 and 70% yields; *β-acetoxyethyl ester* (*glycol monolactate diacetate*), b_{10} 141–5°, b_{763} 265°, d_{25}^{25} 1.1489, n_D^{25} 1.4297, 86% with ketene. C. J. West



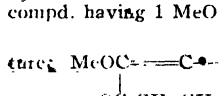
Rotatory power of zinc lactate. W. Dayton Maclay, Raymond M. Hann and C. S. Hudson. *J. Am. Chem. Soc.* **61**, 3234-5(1939); cf. *C. A.* **33**, 6805².—New values are given for the rotation of Zn L-lactate dihydrate; the concn. in H_2O and $[\alpha]_D^{25}$ are: 1.5, −8.7°; 3, −7.9°; 4, −7.5°; 5, −7.1°; 7, −6.6°; $[\alpha]_D^{25}$ −9.2° + 0.4(*c*) in aq. soln. Irvine's procedure (*J. Chem. Soc.* **89**, 935(1906)) for the prepn. of Zn lactates does not cause racemization and is preferable to the more laborious procedure previously reported by M., H. and H. C. J. West

Catalytic hydrogenation of oxides of unsaturated acids. I. G. V. Pigulevskiĭ and Z. V. Rubashko. *J. Gen. Chem.* (U.S.S.R.) **9**, 829-31(1939).—$Me(CH_2)_7CH{-}CH{-}(CH_2)_7CO_2Et$ (3.26 g.) yields 6.1 g. $Me(CH_2)_7CH(OH)$-$CH_2(CH_2)_7CO_2Et$ (I), m. 43–4°, on treatment with H in 30 ml. cold abs. alc. in the presence of 0.3 g. Pd black. On sapon., I gives 10-hydroxystearic acid, m. 82.5°.

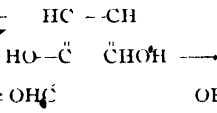
Gertrude Berend

The action of nitrous acid on α-substituted butyrolactones. I. V. V. Feofilaktov and A. S. Onishchenko. *J. Gen. Chem.* (U. S. S. R.) **9**, 304-13(1939).—The action depends on the nature of the substituent in the α-position. α-Acetobutyrolactone (I), b_{18} 130–2°, n_D^{20} 1.4590, d_4^{20} 1.1846 (*semicarbazone*, m. 166–7°), prepd. from $O.CH_2.CH_2$ (II) and $AcCH_2CO_2Et$, with HNO_2 at 0–5° gave the unstable α-nitroso deriv. (blue), which underwent immediate decompn. to give AcOH and α-nitrosobutyrolactone. The latter under the exptl. conditions isomerized to the *anti*-α-oximino deriv. (III), m. 192–3° (70% yield); phenylhydrazone, m. 223°. The reduction of III with Sn and HCl gave (36% yield) α-aminobutyrolactone as the HCl salt (IV), m. 198–200°; chloroplatinate, dark yellow, darkens at 170°, decomps. at 195–7°. α-Carbethoxybutyrolactone (V) with 10% NaOH gave the α-carboxy deriv. (VI), which with HNO_2 also gave III. V, b_{10} 140°, n_D^{17} 1.4500, d_4^{17} 1.1870, prepd. by a modification of Traube's method (*Ber.* **34**, 1976 (1901)), proved to be more stable than I or VI and with HNO_2 at room temp. gave the *α-nitroso deriv.* (VII), obtained partly as a liquid but chiefly (50–6% yield) as a cryst. coupd., m. 97 8° (decompn.), probably the *dimer* (VIII). V satd. with N_2O_3 at 0–5° also gave the 2 forms of VII, but in much lower yield. VIII, insol. or difficultly sol. in org. solvents, when heated in EtOH in a CO_2 atm. readily underwent decompn. to give CO, NO and a *cryst. cmpd.* $C_{20}H_{27}O_{12}N$, m. 162–3° (decompn.), not identified further. VIII saponf. with 20% NaOH gave the α-nitroso deriv. of VI (not isolated), which with dil. acid underwent decompn. and isomerization to give CO_2 and α-oximino-α-hydroxybutyric acid (IX), m. 124-5°; the latter kept in a desiccator for several months slowly isomerized to give III. *α-Cyanobutyrolactone* (X), thick pale yellow oil, b_8 176–8°, n_D^{20} 1.4686, d_4^{20} 1.2501, prepd. from $NCCH_2CO_2Et$ and II in NaOEt (30.4% yield) with HNO_2 at 0–5° gave $C_{10}H_9N_3O_5$, m. 167° (decompn.), apparently a *dimer*, which gave neg. tests for the NO and oximino groups. **The action of phenyldiazonium chloride on α-substituted butyrolactones. II.** *Ibid.* 314-24.—The action parallels that of HNO_2 but differs in that the reaction is not accompanied by polymerization and isomerization. I with PhN_2Cl (XI) at 0–3° underwent cleavage of the Ac group to give (90-6% yield) the phenylhydrazone (XII) of α-ketobutyrolactone, pale yellow, m. 223–4° (decompn.), also obtained in 73% yield from the Na deriv. of I with XI. XII with concd. H_2SO_4 and $K_2Cr_2O_7$ gave a violet coloration (Bulow's reaction for phenylhydrazones). VI with XI under the same conditions as for I also gave XII. Reduction of XII with Sn and HCl gave α-amino-γ-hydroxybutyric acid (XIII) as the HCl salt and this with an excess of freshly pptd. Ag_2CO_3 gave (60–5% yield) XIII, m. 176–7°; reduction of XII with Al or Na amalgams gave $C_{10}H_{12}N_2O_2$, probably the *lactol form* of the phenylhydrazone of α-keto-γ-hydroxybutyraldehyde. XIII with a slight excess of concd. HCl gave IV in quant. yield. V with XI proved

to be stable and gave the *α-phenylazo deriv.* (**XIV**), not purified. To prove its structure **XIV**, which gave a neg. Bülow reaction, was sapond. with dil. NaOH and the sapon. product decarboxylated with dil. H_2SO_4 to give the phenylhydrazone (**XV**) of α-keto-γ-hydroxybutyric acid, bright yellow, m. 162° (decompn.), also obtained by the sapon. of **XII**. **XV** gave a pos. Bülow reaction. **The reaction of α-cyanobutyrolactone with phenyldiazonium chloride. III.** *Ibid.* 325–30.—**X** with **XI** behaves in a manner analogous to that of the monoalkylcyanoacetic esters studied by Favrel (*Bull. soc. chim.* [3], **27**, 193 (1902)). **X** added to a soln. of **XI** at 0–3° gave (98 95% yield) *α-phenylazo-α-cyanobutyrolactone* (**XVI**), bright yellow, m. 101–2° (decompn.), which gave a neg. Bülow reaction. **XVI** with alc. or aq. NaOH underwent ring cleavage and loss of CO_2 to give the phenylhydrazone (**XVII**) of α-keto-γ-hydroxybutyronitrile, pale yellow, m. 168 70°. **XVII** gave a pos. Bülow reaction. **XVII** with 10% HCl gave a HCl salt (**XVIII**), canary-yellow, m. 147–8° (decompn.), which probably exists in 2 tautomeric forms, as the HCl salt of **XVII** and as the HCl salt of 2-imino-3-oxotetrahydrofuran phenylhydrazone. **XVIII** neutralized with aq. KOH gave **XVII**, but with boiling water the product was **XII**. **XVII** with boiling water gave the amide of **XV**, m. 162–3°, which heated with dil. HCl gave **XII**. **Synthesis of hydroxyproline** (γ-hydroxy-



pyrrolidine-α-carboxylic acid). **IV.** *Ibid.* 331–9.—See *C. A.* **33**, 1725[1]. John Livak

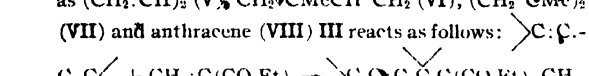


Enzymic preparation of *d*-galacturonic acid. H. H. Mottern and H. L. Cole. *J. Am. Chem. Soc.* **61**, 2701–2(1939).—Polygalacturonic acid (I) is obtained in 75–80-g. yield from 100 g. powd. apple or citrus pectin by wetting with 250 cc. 95% EtOH, adding 10 g. $CaCl_2$ in 250 cc. H_2O and, as soon as the aq. soln. is taken up, 250 cc. 3 *N* NaOH; after stirring 15 min., the clear liquor is decanted and the mixt. is treated with HCl to give a concn. of 1.5% acid and boiled for 10 min.; the I is washed with H_2O contg. 10 cc. concd. HCl per l., then with 50% EtOH and with Et_2O. I (75 g.) in 750 cc. H_2O is treated with 75 cc. 3 *N* NaOH with stirring and the pH adjusted to 3.7 4.0 with NaOH or H_2SO_4, then treated with 3.75 g. of "Pectinol 100D" and PhMe (to prevent mold growth) and kept at 35–40° for 10 days; addn. of dil. H_2SO_4 liberates the galacturonic acid, which is purified by addn. of 95% EtOH and Et_2O and crystn.; the yield is 20 g. C. J. West

Preparation of *d*-galacturonic acid. Ira A. Manville, Francis J. Reithel and Paul M. Yamada. *J. Am. Chem. Soc.* **61**, 2973–4(1939).—Various modifications and suggestions are given for the prepn. of *d*-galacturonic acid from polygalacturonic (pectic) acid by the method of Mottern and Cole (cf. preceding abstr.); yields of 36% have been obtained. C. J. West

Decomposition products of substances containing uronic acid. III. Reductic acid. Kiyosi Aso. *J. Agr. Chem. Soc. Japan* **15**, 161–70(1939).—When the substances contg. uronic acid were heated with mineral acid in an autoclave, reductic acid (I) was produced. Laminaria powder (850 g.) was soaked in 1% HCl overnight and then washed with H_2O. The residue was mixed with H_2O contg. 100 g. of H_2SO_4, dild. to 3 l., and heated at 155–60° for 2.5 hrs. **I**, m. 208°, was isolated from the product. It was sol. in H_2O, alc. and acetone and difficultly sol. in ether, C_6H_6 and ligroin. Anilide, yellow needles, m. 197°; phenylhydrazone, reddish brown needles, m. 246–7°; osazone, yellowish brown plates, m. 208°; trioxime, colorless plates, m. 198–9° (decompn.). A mono-Me ether (**II**), prisms, m. 130–1°, and di-Me ether, colorless sirup, b_{12} 117–18°, were obtained by methylating I with CH_2N_2. The di-Me ether was sapond. to the mono-Me ether, m. 134°. When I was methylated with $MeSO_4$, only the mono-Me ether, m. 134°, was obtained. *p*-Bromophenacyl ester of **II**, needles, m. 91–2°; phenylhydrazone of **II**, yellowish brown plates, m. 208°; trioxime, plates, m. 198–9° (decompn.). The Me group of **II** seemed to be easily removed in the prepn. of the phenylhydrazone and oxime. When I in water was reduced at 190° under 100 atm. pressure for 5 hrs., with Ni as a catalyst, a cryst. product, m. 30°, b. 117–20°, was obtained. It was oxidized to glutaric acid, m. 95–6°, by $KMnO_4$. The product obtained may be 1,2-cyclopentanediol. When I and II were oxidized with alk. $KMnO_4$, succinic acid was obtained. By the oxidation with acid $KMnO_4$ soln. or Ag_2CO_3 colorless plates, m. 183°, were obtained. The formula $C_{12}H_{14}O_6$ is given. The presence of 2 MeO groups was proved. The product is named methylreductic acid oxide (**III**). It was changed into II by dil. HCl and into colorless needles, m. 243–5°, by alc. KOH. The compd. m. 243–5° was an acidic compd. having 1 MeO group. **III** is assigned the structure

The mechanism of the formation of I from uronic acid is represented as follows:



Y. Kihara

The synthesis of *l*-ascorbic acid (vitamin C). V. I. Maksimov, V. V. Nikonova, A. F. Lazarev and L. A. Zvereva. *J. Gen. Chem.* (U. S. S. R.) **9**, 936–43(1939).—A review is given on the different methods used for the synthesis of *l*-ascorbic acid. The most convenient method was found to be that starting with *l*-sorbose via diacetone-2-keto-*l*-gulonic acid. *l*-Sorbose (200 g.), obtained from *l*-sorbitol, which was prepd. from *l*-glucose by catalytic hydrogenation in the presence of Ni at a H pressure of 8 30 atm., gives diacetone-*l*-sorbose (I), m. 77–8°, $b_{0.1-0.3}$ 130–5°, in 90–2% yield, when treated with 4 l. dry acetone, 490 g. dry $CuSO_4$ and 10 g. concd. H_2SO_4 at room temp. for 40 5 hrs. I (600 g.) is dissolved in 6 l. 5% KOH, and 564 g. $KMnO_4$ in 12 l. H_2O is added within 2 hrs. at 18–20° while stirring vigorously. The mixt. is stirred for 4 hrs., filtered, the residue washed with hot H_2O, the filtrate + washing waters neutralized with 15% H_2SO_4 and the soln. evapd. *in vacuo* at 60° to about 1 l. I is extd. by means of $CHCl_3$ or Et_2O. To the aq. soln. of K diacetone-2-ketogulonate are added at 0° 410 g. concd. HCl + 400 g. ice while stirring. The hydrate of diacetone-2-keto-*l*-gulonic acid (II), m. 96–8°, is obtained in 436 456.5 g. yield. *l*-Ascorbic acid is obtained from II either by means of alc. HCl, or on treatment with H_2SO_4 or H_3PO_4.

Gertrude Berend

Diethyl methylenemalonate. G. B. Bachman and H. A. Tanner. *J. Org. Chem.* **4**, 493–501(1939).—A review of the previous work on the reaction of HCHO (I) and $CH_2(CO_2Et)_2$ (II) shows that the yield of di-Et methylenemalonate (III) varies from 0 to 20% owing to the many side reactions which may take place. An extensive study of this reaction is carried out under various conditions. The reaction between I and II in a vapor phase under changing conditions using different catalysts is not improved. The following procedure gives III in 40–45% yield: 200 g. AcOH is added to a mixt. of 30 g. paraformaldehyde, 80 g. II, 5 g. $Cu(AcO)_2$ and 5 g. AcOK. The mixt. is heated on a steam bath until clear and for 1 hr. longer, then distd. at 35 mm. until a b. p. of 130° is reached. After the receiver is changed, the distn. is continued until a b. p. of 200° is reached. The greenish yellow distillate solidifies on standing to a waxy polymer. Redistn. gives a fraction b. 205–15° of almost pure **III**. This is pure enough for further expts. Further purifica-

tion is achieved by repeated fractionation. The purest III b_{760} 210°, n_D^{25} 1.432, d_4^{25} 1.052. III may be considered as an ethylene deriv. with 2 neg. substituents unsymmetrically placed. Such compds. polymerize readily with the formation of resinous products. Unlike maleic anhydride (IV) III does not copolymerize easily. Impure III polymerizes readily to waxy polymers and it becomes more stable on purification. Such impurities which catalyze the polymerization are acrylic acid and Et acrylate. The polymer obtained from highly purified III is a colorless transparent glass which soon becomes a hard brittle porcelain-like solid. It is sol. in AcOH, Me_2CO and EtOH and is pptd. from these solns. as a white powder by pouring into H_2O or petr. ether. It decomps. at 230–40° with formation of the monomer and higher-boiling products. Pure III also copolymerizes with unsatd. compds. such as vinyl acetate, Me methacrylate, Me_2 itaconate, IV, MeCOPr, styrene and vinyl Et ether, with Bz_2O_2 as catalyst. The yields vary from 35 to 90%. III does not resemble IV either in the ease or completeness of its copolymerization with other olefin derivs. With dienes such as $(CH_2{:}CH)_2$ (V), $CH_2{:}CMeCH{:}CH_2$ (VI), $(CH_2{:}CMe)_2$ (VII) and anthracene (VIII) III reacts as follows:

III and V react at room temp. on standing for 24 hrs. to give *1,1-dicarbethoxy-3-cyclohexene* in 80% yield, b_6 117°, n_D^{25} 1.452, d_4^{25} 1.020. III and VI when heated at 100° for 3 hrs. yield *1,1-dicarbethoxy-3(or 4)-methyl-3-cyclohexene* in 86% yield, b_6 127°, n_D^{25} 1.456, d_4^{25} 1.030. III and VII give under the same conditions, *1,1-dicarbethoxy-3,4-dimethyl-3-cyclohexene* (IX) in 91% yield, b_6 136°, n_D^{25} 1.460, d_4^{25} 1.038. Sapon. of IX with alc. NaOH yields *1,1-dicarboxy-3,4-dimethyl-3-cyclohexene* (X) in 86% yield, m. 186.5–88° (CO_2 evolution). When heated at 205° until the CO_2 evolution has ceased, X gives, in 85% yield, *3,4-dimethyl-3-cyclohexene-1-carboxylic acid*, m. 80–1°. III and VIII heated at 220° give a condensation product in 54% yield, m. 126–7°. F. E. Brauns

Substituted dialuric and hydurilic acids. C. M. Manberg and D. W. Stanger. *J. Am. Chem. Soc.* **61**, 2736–7 (1939). 5-Isoamylbarbituric acid (I) (2.1 g.) and 25 cc. of 3% H_2O_2, refluxed 1 hr., give about 2 g. of *5-isoamyldialuric acid* (II), m. 179.5. I (12.7 g.) in 100 cc. H_2O and 1.5 cc. concd. H_2SO_4, oxidized by slow addn. of 0.2 *N* $KMnO_4$ (600 cc., with addn. of 1 cc. H_2SO_4 after 400 cc. $KMnO_4$ has been used), give a ppt. from which Me_2CO exts. 5.3 g. of *5,5'-diisoamylhydurilic acid* (III), m. 290° (decompn.), and from the filtrate 3.4 g. of II. *5-Bz deriv.* of II, m. 210.5–16°. Hydrolysis of II gives isoamyltartronic acid. Solns. of the Na salts of I and II and of the corresponding Et compds. have no appreciable effect when injected into rats. C. J. West

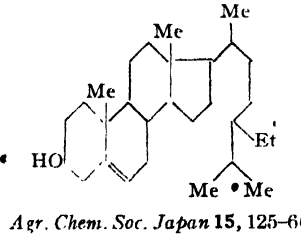
Alkylacetanilidobarbituric acids. II. *p*-Ethoxy derivatives. John A. Timm. *J. Am. Chem. Soc.* **61**, 2962 (1939); cf. *C. A.* **30**, 7552⁷.—The appropriate 5-alkylbarbituric acid and *p*-$EtOC_6H_4NHCOCH_2Cl$, 1.5 mol. proportion of AcONa and 0.25 mol. proportion of KI in 70% EtOH, heated 24 hrs., give the following *5-p-ethoxyacetanilidobarbituric acids* (all m. with decompn.): *5-Et* m. 194–205°, 60%; *5-iso-Pr* m. 210–15°, 20%; *5-Bu* m. 231–2°, 40%; *5-iso-Bu* m. 217–19°, 50%; *5-iso-Am* m. 219–20°, 80%; *5-allyl* m. 215–18°, 60%. C. J. West

Preparation of *d*- and *l*-ribosidodihydroxyacetone tetraacetates with an ortho-ester structure. Clarence W. Klingensmith and Wm. Lloyd Evans. *J. Am. Chem. Soc.* **61**, 3012–15(1939); cf. *C. A.* **30**, 482¹; **33**, 143⁸.—*l-Ribose tetraacetate* (I), m. 109.5–10° (all m. ps. cor.), $[\alpha]_D^{25}$ 56° ($CHCl_3$, *c* 3.5). A mixt. of I and the *d*-isomer gives the *dl-compd.*, m. 88–90°, which is probably a mol. compd. I gives 69–70% of *acetobromo-l-ribose* (II), m. 94.5–5.5°, $[\alpha]_D^{25}$ 224.8° ($CHCl_3$, *c* 3.1). The *d*-isomer of II in C_6H_6, added to $AcOCH_2Ac$ contg. I as a catalyst, gives 18–20% of *di-Ac d-ribose-1,2-ortho-3'-acetoxyacetonyl acetate* (III), m. 97–8°, $[\alpha]_D^{25}$ −11.6° ($CHCl_3$, *c* 1.8); it is very sensitive to HCl in $CHCl_3$, a very rapid change in rotation taking place in 6 min. (−0.32 to −3.03°); the soln. apparently contains acetochloro-*d*-ribose (IV). Similarly II gives the *l-isomer* of III, m. 97–8°, $[\alpha]_D^{25}$ 11.8° ($CHCl_3$, *c* 3.2); with HCl in $CHCl_3$ the rotation changes from 0.95 to 9.45° in 5 min. and the presence of the *l*-isomer of IV is indicated. The *dl-isomer* of III m. 124.5–5° and is a true racemate. These are the 1st examples of ortho-ester derivs. which contain a group other than the Me and Et groups as a part of the ortho structure. A possible explanation for the high A_D values of III by the Kunz and Hudson method is presented. C. J. West

Action of titanium tetrachloride on benzyl glucopyranoside tetraacetates. E. V. Piel and C. B. Purves. *J. Am. Chem. Soc.* **61**, 2978–9(1939).—The reaction of $TiCl_4$ with tetraacetyl-β-benzylglucopyranoside (I) in $CHCl_3$ (refluxing 75 min.) gives an equil. mixt. contg. 90% of the α-isomer (II); the same equil. mixt. is obtained from II. By attention to tech. details 60% yields of II may be obtained from acetobromoglucose. Although colored addn. compds. were formed with tetraacetyl-β-methylfructopyranoside, sucrose acetate or tetraacetyl-β-glucosan, the $TiCl_4$ compds. are apparently too stable to rearrange under the exptl. conditions and the original materials were recovered unchanged. C. J. West

Photochemical production of reducing sugars from glycosides by ultraviolet light. Lawrence J. Heidt. *J. Am. Chem. Soc.* **61**, 2981–2(1939).—Aq. solns. of α- and β-Ph, α- and β-benzyl and β-(β-phenylethyl) glucopyranosides and of β-benzyl fructopyranoside (I) were illuminated with ultraviolet light in quartz tubes; reducing sugars were formed. Three samples of I showed 9, 14 and 18% hydrolysis as detd. by change in rotation or by detn. of the reducing sugar. The photochem. efficiency was independent of the light intensity when 5 to 700 × 10^{16} photons were absorbed per min. by 11 cc. of soln. and also of pH between 3.5 and 6.5. Gross quantum yields were independent of the initial concn. of glycoside but decreased as the liberated alc. or phenol absorbed a large fraction of the light incident on the soln. C. J. West

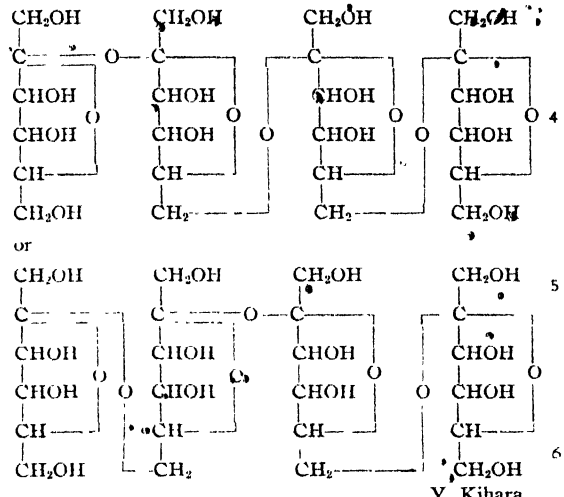
The antiketonic action of glucose. Giuseppe Illari. *Biochim. terap. sper.* **26**, 380–90(1939).—Glucose and $AcCH_2CO_2Et$ react in an aq. medium slightly alk. with KOH. The optimal condition, as detd. by measuring the optical rotation, is found in dil. solns. when glucose, ester and KOH are present in the mol. proportion 1 2.1. This supports Schaffer's theory that the antiketonic effect of glucose is due to a reaction with $AcCH_2CO_2H$. A. E. Meyer



A kinetic study of the formation of *d*-glucose phenylhydrazone. A. Orning and G. H. Stempel, Jr. *J. Org. Chem.* **4**, 410–17(1939).—The reaction between equil. *d*-glucose and a mixt. of $PhNHNH_2$ and its HCl salt is studied under carefully controlled conditions, a specially designed polarimeter tube being used. The results, which are given in tables and curves, are discussed and the kinetics of the reaction is expressed by math. equations. When all the oxidizing agents, including dissolved air, are eliminated, there is no evidence for the formation of an osazone. From the results it is concluded that the formation of *d*-glucose phenylhydrazone is due to a reaction between $PhNHNH_3^+$ and an intermediate substance which is symmetrically related to the isomeric form of *d*-glucose. The reverse reaction is an acid-catalyzed hydrolysis. F. E. Brauns

Ketone sugar series. IX. The validity of Hudson's rules of isorotation in the *l*-sorbose series. β-Ethyl sorboside and its tetraacetate. Eugene Pacsu. *J. Am. Chem. Soc.* **61**, 2669–74(1939); cf. *C. A.* **31**, 6620⁶.—It is shown that Hudson's rules of isorotation hold closely in the *l*-sorbose series provided that the a_x consts. for the ketoses are applied separately to the α- and β-derivs. The rotations of the α- and β-isomers can be calcd. by introduction of a factor *F* in the equations: $[M]_\alpha = -a_x + (b_{\alpha,\beta} + F)$ and $[M]_\beta = a_x + (b_{\alpha,\beta} - F)$. The numerical value of *F* has been detd. to be 6850 for the acetylated and 8800 for the deacetylated products. Similarly, by introduction of a factor (*F*) in the equations, the rotation of α-

and β-mannose can be calcd. from the "normal" A_{OH} value for the aldoses. It is suggested that *F* represents the numerical value of the contribution of a new optical factor (ring conformations) to the total rotation of the mole. The reaction between α-acetochlorosorbose and MeOH or EtOH gives rise to ortho esters, as the main products and only to a small quantity of the true β-alkyl sorboside tetraacetates. The *β-isomer* m. 86°, $[\alpha]_D^{20}$ 82.7°, $[\alpha]_C^{20}$ 66°, $[\alpha]_{Hg1}^{20}$ 98° (0.200 g. in 10 cc. $CHCl_3$). The pyranoid ring structure of α-Me and β-Et sorboside is proved by the HIO_4 oxidation method of Jackson and Hudson. **X. The synthesis of a new disaccharide, 1-β-glucosidofructose, and the structure of turanose and melezitose.** Eugene Pacsu, E. Justin Wilson, Jr. and Ladislas Graf. *Ibid.* 2675-9.—The present structures of turanose and melezitose are based on the supposed 1,3,4-trimethylfructose, a sirupy product obtained by Zemplén and Braun (*C. A.* **21**, 392) and by Leitch (*C. A.* **21**, 1969) from the fully methylated melezitose. The existence of the true, cryst. 1,3,4-trimethylfructose and the no. and properties of the octaacetates and other derivs. of turanose indicate that neither C atom 5 nor 6 of the fructose part of turanose can carry the glucosidic linkage. C atom 4 is also eliminated because turanosazone is not identical with maltosazone. If C atom 1 were the position of the linkage, 1-β-glucosidofructose would be the β-glucosidic isomer of turanose. β-Diacetonefructose (26 g.) and acetylbromoglucose with Ag_2O in $CHCl_3$ give 30.5 g. of *1-tetraacetyl-β-glucosido-2,3,4,5-diacetone-β-fructopyranose* (I), m. 162–3°, α_D^{25} −32.9° ($CHCl_3$, *c* 2.374); with MeOH-MeONa 60 g. I gives 42 g. *1-β-glucosido-2,3,4,5-diacetone-β-fructopyranose*, m. 174.5°, $[\alpha]_D^{20}$ −45.6° (H_2O, *c* 0.986); heating with 5% AcOH at 100° for 6 hrs. gives *1-β-glucosidofructose*, which seps. from H_2O as the dihydrate, m. 132-5°, $[\alpha]_D^{25}$ −59.2° (H_2O, *c* 1.3328). This new sugar is entirely different from turanose and, unlike the latter, it does not give an osazone except for a small quantity of glucosazone. Turanose, therefore, must be 3-α-glucosidofructose and melezitose the corresponding sucrose deriv. Based on the true formula of turanose, the correct structures of the more important turanose derivs are given. C. J. West



Relations between rotatory power and structure in the sugar group. XXXIV. The possibility of different conformations of the pyranoid ring. C. S. Hudson. *J. Am. Chem. Soc.* **61**, 2972(1939); cf. *C. A.* **33**, 6804⁸.—The agreement of rotational differences within the α- and β-series, when coupled with the known disagreement across the α-β pair, probably indicates differences in pyranoid ring conformation. Cf. preceding abstr. C. J. West

Waxy substances of sugar cane. III. A new sterol and a new sterol ketone in the unsaponifiable matter of cane wax. Tetuo Mitui. *J. Agr. Chem. Soc. Japan* **15**, 526-30(1939); cf. *C. A.* **32**, 6254⁸.—The unsaponifiable matter of cane wax was treated with acetone to remove the cryst. substances. A reddish brown oil was extd. with cold MeOH. By treating the ext. with C_6H_6, a cryst. product, m. 206°, was obtained. The formula $C_{29}H_{52}O_2$ is given. It is named α-saccharostanediol. The yield was 4% for the wax. A dibenzoate, m. 158 60°, and di-*m*-dinitrobenzoate, m. 171° (decompn.), were prepd. α-Saccharostanediol gave no reaction with $C(NO_2)_4$ or Br. It showed a Co-blue color with $SbCl_3$-$CHCl_3$. One alc. residue may be present at C atom 3 of the sterol nucleus. The mother liquor of α-saccharostanediol was kept at 0° and satd. with HCN. Sitosterol allophanate crystd. out, by treating the filtrate of sitosterol allophanate with acetone and MeOH, colorless scales, m. 106°, were obtained. The formula $C_{29}H_{48}O$ is given. The substance is named β-saccharostenone. The yield was 0.1–0.2% of the wax. An oxime, m. 163-5°; 2,4-dinitrophenylhydrazone, m. 211°, and tribromide, m. 160°, were prepd. It showed a yellow color with $C(NO_2)_4$-$CHCl_3$. **IV. Diol derivatives of cane sitosterol and stigmasterinol.** *Ibid.* 795–804.—Cane sitosteryl acetate (I) was oxidized with SeO_2 and then the product was acetylated. When it was treated with Ac_2O, a cryst. mixt. (II) was isolated from the insol. part, and a cryst. compd., m. 249°, (III) from the sol. part. II was sepd. into 1 part of a compd. m. 198° and 2 parts of a compd. m. 164°. The former was identified as 5-stigmastene-3,4-diol diacetate and the latter as 5-sitostene-3,4-diol diacetate. The latter was hydrogenated with Pt oxide as the catalyst and then sapond. with alkali. Crystals m. 199° were obtained. The compd. was difficultly sol. in ether and showed no Liebermann-Burchard reaction. It was identified as cane sitostane-3,4-diol. From the fraction easily sol. in ether, a cryst. product m. 84° was obtained. It was identified as sitostane. III was identified as cane 4-sitostene-3,6-diol. When it was acetylated and then hydrogenated, only sitostane was obtained. From stigmasteryl acetate, 5-stigmastene-3,4-diol and 4-stigmastene-3,6-diol, m. 236°, were prepd. by a similar process. The catalytic hydrogenation of 5-stigmastene-3,4-diol diacetate, m. 198°, gave stigmastane-3,4-diol, m. 236° and stigmastane, m. 84°. The former gave no depression of the m. p. by heating with cane sitostane-3,4-diol. The latter was also identified with stigmastane prepd. from stigmastanol or cane sitostane. When 4-stigmastene-3,6-diol was hydrogenated, only stigmastane was obtained. When I was treated with fuming HNO_3, the nitrate, m. 72°, was obtained. It was changed into 6-oxositostanyl acetate m. 129°, by treating with Zn and glacial AcOH. Sitostane-3,6-diol, m. 215°, was prepd. by reducing it with PrONa. It formed colorless scales difficultly sol. in ether. Stigmastane-3,6-diol was also prepd. from stigmasteryl acetate through the nitrate, m. 127°, Δ^{22}-6-oxosteryl acetate, m. 140°, and Δ^{22}-stigmastene-3,6-diol, m. 200°. It formed scales, m. 213°, and was identified as sitostane-3,6-diol. I was oxidized with CrO_3 in AcOH to 7-oxositosteryl acetate, m. 170°. It was dissolved in the mixt. of ether and AcOH and then hydrogenated, with a small amt. of Pt oxide. 7-Oxositostanyl acetate, m. 162°, was obtained. It was reduced to sitostane-3,7-diol, m. 176°, by means of NaOPr. It crystd. in plates from the ether soln. Simultaneously sitostanol, m. 128–33°, was obtained. Stigmasteryl acetate was also oxidized to 7-oxostigmasteryl acetate, m. 183°, by treating with CrO_3, and then hydrogenated to 7-oxostigmastanyl acetate, m. 161°. It was reduced to stigmastane-3,7-diol with NaOPr. It forms crystals, m. 174°, and was also identified as sitostane-3,7-diol. Di-3,5-dinitrobenzoate, m. 207.5°. α-Saccharostanediol was not identical with these diol derivs. prepd. The diol derivs. of sitostane were identical with those of stigmastane. Hence the constitution of the side chain of cane sitosterinol may be —$CHMeCH_2CH_2CH$-$EtCHMe_2$. **V. Oxidation of cane sitostanyl acetate and stigmastanyl acetate by chromic acid.** *Ibid.* 805-8.—Sitosteryl acetate was hydrogenated into sitostanyl acetate and then oxidized with CrO_3 and AcOH. From the neutral fraction of the oxidation products, the semicarbazone, m. 261-2°, was prepd. It was identified as *trans*-androsterone acetate semicarbazone. From the acid fraction a Na salt was isolated. It was sapond. to an acid m. 221-2°. Me ester, m. 154°; Me ester acetate, m. 158°. The acid was identified as 3-hydroxynorallocholanic acid. Simultaneously a cryst. product m. 238° was isolated from the acid fraction; di-Me ester, m. 78°. The substance was identified as 3-hydroxyetiobilianic acid. These compds. were also isolated from the oxidation products of stigmastanyl acetate. Hence the constitution of cane sitosterol may be 22-dihydrostigmasterinol having the following formula:

Carbohydrates of the bulbs of Allium. IX. Yosiziro Kihara. *J. Agr. Chem. Soc. Japan* **15**, 348–52(1939); cf. *C. A.* **31**, 8605⁹.—Half of scorodose was hydrolyzed when it was kept with *N* H_2SO_4 at 20° for 220 min. A few products were prepd. by the partial hydrolysis of scorodose. They were *l*-rotatory. Scorodose was scarcely hydrolyzed by cold 10% AcOH, while it was easily hydrolyzed by hot 2.5% AcOH. Methylscorodose was hydrolyzed with oxalic acid on the water bath for 15 hrs. The hydrolyzate was methylated with MeOH contg. HCl and then distd. into fractions in a high vacuum. A large amt. of colorless sirup $b_{0.10}$ 81–9° was obtained. It was identified as 1,3,4,6-tetramethylmethylfructoside. From the fraction $b_{1.7}$ 102–5°, a faint yellow sirup was obtained, $[\alpha]_D^{20}$ 13.0° in H_2O. It may be 1,3,4-trimethylmethylfructoside. It was hydrolyzed with HCl and then oxidized with Br. The change of the optical rotatory power was slow. Trimethylfructose may be 1,3,4-trimethylfructofuranose. From these facts the constitution of scorodose is assumed to be

or

Y. Kihara

Cyclopropanone. N. Ya. Dem'yanov and V. V. Feofilaktov. *J. Gen. Chem.* (U. S. S. R.) **9**, 340–60(1939) — Repetition of Ingold's synthesis (*C. A.* **16**, 3068) of cyclopropanone (I) gave neg. results. Et 1-cyanocyclopropane-1-carboxylate (II), b. 208–11°, with EtOH-HCl underwent cleavage of the ring to give chiefly *di-Et ω-chloroethylmalonate*, $Cl(CH_2)_2CH(CO_2Et)_2$, viscous oil, b_{24} 145°, $n_D^{16.5}$ 1.4416, $d_4^{16.5}$ 1.13105, M. R. 52.01 (calcd. 52.94), and only a small amt. of $(CH_2)_2C(CO_2Et)_2$ (III). II with alk. 10% H_2O_2 at room temp. for several days gave 40–1% $(CH_2)_2C(CONH_2)CO_2Et$, m. 125°, which with concd. NH_4OH gave 80% $(CH_2)_2C(CONH_2)_2$ (IV), m. 192–4°, whose Br deriv., $C_5H_6N_2Br_2$ (V), pale yellow, decomps. 158–9°. III, b. 216–17°, prepd. from $(CH_2)_2Br_2$ and $CH_2(CO_2Et)_2$, with concd. NH_4OH, also gave 72–5% IV. V with MeONa gave 5-cyclopropanespirohydantoin, m. 213–14°, from which 1-carbamidocyclopropane-1-carboxylic acid (VI) was obtained by heating with NaOH and acidifying with HCl. VI with HNO_2 gave the 1-nitroso deriv.; the filtrate from this deriv. contained 1-aminocyclopropane-1-carboxylic acid, isolated as the HCl salt (VII), m. 220–1° (decompn.). The action of alkali on the NO deriv. or of HNO_2 on the NH_2 deriv. gave 1-hydroxycyclopropanecarboxylic acid (VIII), m. 109–10°, whose acetate m. 96–7.5°. VIII with concd. H_2SO_4 at 125–30° or heated up to 320° failed to give either I or acrolein. VIII with HBr in a sealed tube at 100° for 4 hrs. gave a dibasic acid, $C_8H_{10}O_6$, m. 154.5–5.0° (decompn.), the structure of which was not detd. VIII with HBr in a sealed tube at 170° for 3.5 hrs. gave α-aminobutyrolactone as the HBr salt, m. 216–22.5° (decompn.), which with freshly pptd. Ag_2CO_3 at 35° gave α-amino-γ-hydroxybutyric acid, m. 189–90° (Cu salt, blue-violet). Although VIII behaved as a monobasic HO acid, further study revealed that it readily decolorized $KMnO_4$, underwent oxidation with great ease, and gave a characteristic reddish brown coloration with $FeCl_3$. These unusual properties suggested the possibility that in the prepn. of VIII from VII rupture of the nucleus and isomerization had occurred to give an unsatd. acid, possibly *trans*-γ-hydroxycrotonic acid (IX), m. 106.5–7.0°, whose acetate m. 94°. IX was synthesized by the method of Rambaud (*C. A.* **27**, 2423) but its mixed m. p. (68–71°) with VIII proved the nonidentity of the 2 compds. The structure assigned to VIII requires further study. 42 references. John Livak

The behavior of the cis and trans forms in the dehydration of 1-methyl-1,2-cyclopentanediol and in the dehalogenation of the corresponding halohydrins. Marc Tiffeneau and Georges Vajssière. *Compt. rend.* **209**, 449–53 (1939).— By treatment of *cis*-2-chloro-1-methylcyclopentanol, b_{18} 61–4°, in anhyd. Et_2O with BrMgEt, the corresponding bromomagnesium deriv. was produced with the simultaneous liberation of C_2H_6. Upon heating the reaction product on a water bath until the ether was removed and decompg. with H_2O, 2-methylcyclopentanone was formed. The trans form yielded the same product when treated similarly. Dehydration of *cis*-1-methyl-1,2-cyclopentanediol by heating with 10% H_2SO_4 yields 2-methylcyclopentanone, b_{18} 44°; semicarbazone, m. 184°. The trans glycol, m. 64°, when treated similarly with hot dil. H_2SO_4, yielded a resinous material. Passage of the vapors at 20 mm. of the trans glycol over Al heated at 300° yielded an unsatd. volatile hydrocarbon and a resin resulting from polymerization of the former, and also a small quantity of 2-methylcyclopentanone. Thus the principal reaction consisted in an elimination of 2 OH group and H from an adjacent CH_2 group, yielding an unsatd. hydrocarbon which was then polymerized. The distant positions of the OH groups in the trans form and their adjacent position in the cis form accounts for the differences noted in the dehydration studies. W. A. Cook

Synthesis of *tert*-butyl- and *tert*-amylcyclopentane and of their intermediate products. Herman Pines and V. N. Ipatieff. *J. Am. Chem. Soc.* **61**, 2728–30(1939).—Hydrogenation of 10 parts of *p-tert*-BuC_6H_4OH with 1 part of Ni under 100 atm. H at 125° in an Ipatieff-type electrically-heated rotating autoclave gives 4-*tert*-butylcyclohexanol (I), m. 82°; *4-tert-amylcyclohexanol*, b_{10} 154–5°, m. 24–5°, d_4^{20} 0.9034; *α-naphthylurethan*, m. 113°. Heating 1 mole of I with 560 cc. of 50% HNO_3 and 0.5 g. NH_4 vanadate gives 87% of *β-tert-butyladipic acid* (II), m. 117°; *β-tert-amyladipic acid*, m. 77–8°, 95% yield. II (180 g.) and 18 g. $Ba(OH)_2$, heated at 280°, give 64–70% of *3-tert-butylcyclopentanone* (III), b_{759} 200–1°, d^{20} 0.9031, n_D^{20} 1.4505 (*semicarbazone*, m. 194–4.5°; *2,4-dinitrophenylhydrazone*, m. 139°); *3-tert-amylcyclopentanone*, b_{27} 120°, d^{20} 0.9159, n_D^{20} 1.4601 (75–80% yield) (*semicarbazone*, m. 189°; *2,4-dinitrophenylhydrazone*, m. 174.5°). Reduction of 10 parts of III with 1 part of Ni catalyst at 80° and 100 atm. initial H pressure gives *3-tert-butylcyclopentanol* (IV), b_{744} 196–8°, d^{20} 0.9096, n_D^{20} 1.4574 (*α-naphthylurethan*, m. 95°); *3-tert-amylcyclopentanol*, b_{738} 217°, d^{20} 0.9114, n_D^{20} 1.4656 (*α-naphthylurethan*, m. 82°). Catalytic reduction of V with Ni and 100 atm. H gives *tert-butylcyclopentane*, m. −96 ± 0.2°, b_{760} 145.2°, dT/dP (770 to 730 mm.) = 0.052°/mm., d^{20} 0.7911, d^{40} 0.7753, n_D^{20} 1.4341, $n_{H\beta}^{20}$ 1.4396, $n_{H\alpha}^{20}$ 1.4320, Δ^{20} 76.4, δ^{20} 96.6. *tert-Amylcyclopentane*, b_{760} 173.9°, dT/dP (770 to 730 mm.) = 0.054°/mm., d^{20} 0.8071, d^{40} 0.7923, n_D^{20} 1.4457, $n_{H\beta}^{20}$ 1.4511, $n_{H\alpha}^{20}$ 1.4433, Δ^{20} 78, δ^{20} 96.6. C. J. West

Sulfonation reactions with sulfuryl chloride. M. S.

Kharasch and Alice Tanner Read. *J. Am. Chem. Soc.* **61**, 3089–92(1939).—Chlorination reactions with SO_2Cl_2 (*C. A.* **33**, 7728[8]) occur with many types of org. moles with a peroxide catalyst. If the mechanism is a chain reaction involving the formation of Cl atoms and SO_2Cl free radicals then sulfonation as well as chlorination should take place by the direct action of the SO_2Cl radical on the hydrocarbon. Results are given for cyclohexane with a large no. of catalysts and for PhMe, PhEt, heptane, C_6H_6, *tert*-BuPh and methylcyclohexane with selected catalysts. The catalyst, more than any other factor, dets. the course of the reaction. Under similar conditions of light and low SO_2Cl_2 concn., peroxides give chlorination only; anthraquinonesulfonic acids give almost entirely chlorination; mercaptans and org. N compds. give chlorination and sulfonation, the best yields of sulfonation product being obtained with the aromatic ring compds. With any 1 catalyst, the most favorable conditions for sulfonation are a strong light and a low concn. of SO_2Cl_2 in the reaction mixt. at any 1 time. O, which might be expected to inhibit chlorination, inhibits both reactions in diffused light and has no appreciable effect in strong light, except in the case of the C_5H_5N type of catalyst, where chlorination is somewhat inhibited but the yield of cyclohexanesulfonyl chloride is increased. SO_2, which in excess favors sulfonation when a mixt. of SO_2 and Cl is used, has no effect with SO_2Cl_2 in strong light and inhibits both reactions in diffused light. The mechanism of the reaction is discussed. C. J. West

The addition of hydrogen to acetylene derivatives. XXXI. Catalytic hydrogenation of acetylene γ-glycols containing cyclopentyl radicals. Yu. S. Zal'kind and I. M. Gverdtsiteli. *J. Gen. Chem.* (U. S. S. R.) **9**, 855–62 (1939); cf. *C. A.* **33**, 4195[2].—To (ClCMgBr)$_2$, prepd. from 12 g. Mg, 55 g. EtBr and CHCl, there is added 42 g. cyclopentanone while cooling and stirring. After 24 hrs. the mixt. is decompd. and the reaction product extd. with Et_2O. The residue from Et_2O gives bis(1-hydroxycyclopentyl)acetylene (I), m. 109.8–10.8°, in 45.2% yield. I yields acetylene on warming with 40% KOH soln. and gives a violet color with concd. H_2SO_4. It is slightly sol. in C_6H_6, rather sol. in alc. and Et_2O. The filtrate from I gives 1-ethynyl-1-hydroxycyclopentane, b. 145–50°. I in alc. contg. colloidal Pd is hydrogenated to bis(1-hydroxycyclopentyl)ethylene (II) which is obtained in 2 isomeric forms, m. 129.6–30.6° (III) and 82–3° (IV), resp. Both isomers give a bright-violet color with H_2SO_4. 1,2-Bis(1-hydroxycyclopentyl)ethane (V), m. 131.2–1.4°, is obtained from I on hydrogenation in the presence of Pt. III and IV yield the γ-oxide, m. 81–2°, on heating with a crystal of I; it is also obtained on warming III with H_2SO_4. The diacetate of I, m. 44.5–5.5°, prepd. by heating 12 g. I, 36.5 g. Ac_2O and 1 g. NaOAc, is easily sol. in alc., Et_2O, ligroin and MeOH and yields on hydrogenation in the presence of colloidal Pd the diacetate of V, b_7 108 10° (partial decompn.), d^{16} 1.0004, n_D^{18} 1.47507. When the hydrogenation is stopped after the addn. of 2 atoms H, the diacetate of II is obtained, b_7 126.5–9° (partial decompn.), d^{13} 1.072. To EtMgBr prepd. from 24 g. Mg and 110 g. EtBr is added in small portions 42 g. dimethylethynylcarbinol within 1.5 hrs. while cooling and stirring. The mixt. is heated for 15 min. and allowed to stand for 2–3 hrs. Then 42 g. cyclopentanone is added slowly while cooling. After 24 hrs. the mixt. is heated with moist Et_2O. The residue from Et_2O is distd. with steam, and the residue from the steam distn. is extd. with Et_2O. After evapn. of the Et_2O dimethyl(1-hydroxycyclopentylethynyl)carbinol (VI) m. 56–8°, b_6 125–6°, is obtained, which is easily sol. in org. solvents. Hydrogenation of VI in the presence of colloidal Pd gives dimethyl(1-hydroxycyclopentylvinyl)carbinol, m. 89–90°. G. B.

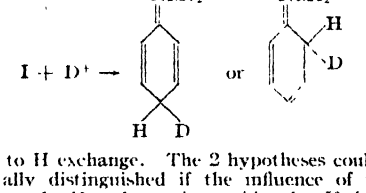
Hydrogenation of cyclohexene with copper catalysts. Sigeru Tutumi. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 360–2(1939); cf. *C. A.* **33**, 9104[2].—The activities of the following catalysts were tested by the flow method: Cu-66% kieselguhr, Cu-100% kieselguhr, Cu-133% kieselguhr, Cu-10% Al_2O_3, Cu-10% Al_2O_3-100% kieselguhr, Cu-10% Cr-100% kieselguhr, Cu-10% ThO_2-100% kieselguhr, and Cu-10% MgO. Al_2O_3, ThO_2, and Cr were superior promoters. An 81.8% yield was obtained with a Cu (6 g.)-10% Al_2O_3 catalyst at 170° and atm. pressure. In all cases the optimum temp. was 170°. The catalysts were prepd. by pptn. from mixed nitrates by K_2CO_3 in the presence or absence of kieselguhr, washing with hot water, drying at 200°, and reducing at 200° for 1 hr. Wm. E. Trout, Jr.

The catalytic conversion of 5-cyclohexyl-1-pentene and 5-cyclohexyl-1-pentyne. R. Ya. Levina, G. B. Golub and K. M. Smirnov. *J. Gen. Chem.* (U. S. S. R.) **9**, 825–8(1939); cf. *C. A.* **31**, 4652[1,5].—β-Cyclohexylethyl alc., b_{22} 105–7°, d_4^{20} 0.9189, n_D^{20} 1.4656, obtained from $C_6H_{11}CH_2MgI$ and CH_2O, was transformed to $C_6H_{11}CH_2CH_2I$, b_{11} 98–100°, d_4^{20} 1.4530, n_D^{20} 1.5230. 5-Cyclohexyl-1-pentene (I), b_{14} 83–4°, d_4^{20} 0.8168, n_D^{20} 1.4550, was obtained from $C_6H_{11}CH_2CH_2MgI$ on reaction with CH_2:$CHCH_2Br$. I conducted over platinized charcoal (25% Pt) at 200–5° in a weak CO_2 current at a rate of 2–3 drops a min. is completely transformed into a mixt. of amylcyclohexane (II), b_{750} 198–9°, d_4^{20} 0.8018, n_D^{20} 1.4438, and amylbenzene (III), in the ratio 2:1. 5-Cyclohexyl-1-pentyne, b_8 73–4°, d_4^{20} 0.8464, n_D^{20} 1.4627, prepd. by the method of Bourguel (cf. *C. A.* **19**, 3476) via the intermediates $C_6H_{11}CH_2C{:}CH \rightarrow C_6H_{11}CH_2C{:}CMe \rightarrow C_6H_{11}CH_2CH_2C{:}CH \rightarrow C_6H_{11}CH_2CH_2C{:}CMe \rightarrow C_6H_{11}CH_2CH_2CH_2C{:}CH$, when conducted over platinized charcoal under the same conditions as I, yielded II and III in the ratio 1:2. Gertrude Berend

Hydrogenation velocities of aromatic hydrocarbons. III. Reaction velocity and structure of hydrocarbons. A. V. Lozovoĭ and M. K. D'yakova. *J. Gen. Chem.* (U. S. S. R.) **9**, 895–901(1939); cf. *C. A.* **32**, 5286[4], 5287[4].—Hydrogenation velocities were detd., with Ni + Al_2O_3 as a catalyst, of a no. of aromatic hydrocarbons to establish the influence of the structure on hydrogenation velocity. A comparison of the hydrogenation velocities of benzene homologs, such as toluene up to octylbenzene, showed that the lengthening of the aliphatic side chain from 1 to 8 C atoms had little influence on the velocity with which H was absorbed by the aromatic ring. The hydrogenation velocities of AmPh, iso-AmPh, *p*-$Pr^iC_6H_4Me$ and *p*-cymene revealed that branching of the side chain did not influence the hydrogenation velocity. *o*-Xylene, tetralin and *o*-$Pr^iC_6H_4Me$ absorb H with the same velocity. From the present and previous expts. it is concluded that neither the length nor the structure of aliphatic side chains exerts any practical influence on H absorption by the benzene nucleus in the presence of a Ni catalyst. The hydrogenation velocity is, however, influenced by the no. of substituents present in the benzene nucleus, e. g., the absorption of H becomes more difficult with an increasing no. of substituents. Gertrude Berend

The synthesis and properties of α-methylheptylbenzene, α-butylamylbenzene and α-hexylheptylbenzene. A. D. Petrov, A. P. Baĭdanov, N. N. Zakotin and P. I. Suntsov. *J. Gen. Chem.* (U. S. S. R.) **9**, 509–12(1939).—$C_6H_{13}MgBr$ and MeCOPh give *methylhexylphenylcarbinol*, b_{12} 136–7°, d_4^{14} 0.9426, n_D^{15} 1.50214, M. R. calcd., 64.776, M. R. found, 64.55. When this is heated with I, it gives *2-phenyl-2-octene*, b_{10} 121–2°, d_4^{17} 0.8810, n_D^{17} 1.49459, M. R. calcd., 62.784, M. R. found, 62.64. Hydrogenation gives *2-phenyloctane*, b_{18} 125–7°, d_4^{17} 0.8626, d_{20}^{20} 0.8526, n_D^{17} 1.48790, M. R. calcd., 63.251, M. R. found, 63.39, η_{20} 2.460, η_{50} 2.009. At −80° this is a thick, glassy mass. In a similar way, BuMgBr and BzOEt give *phenyldibutylcarbinol*, b_{7-8} 130–2°, d_{16}^{16} 0.9437, n_D^{18} 1.50602, which dehydrates to *5-phenyl-4-nonene*, b_6 117–21°, d_{20}^{20} 0.8882, n_D^{20} 1.5012, M. R. calcd., 67.4, M. R. found, 67.02, and this is hydrogenated to *5-phenylnonane*, b_{12} 126–7°, d_{20}^{20} 0.8596, d_{50}^{50} 0.8477, $n_D^{18.5}$ 1.4874, M. R. calcd., 67.87, M. R. found, 67.63, η_{20} 2.747, η_{50} 2.078. *Dihexylphenylcarbinol*, b_6 165–70°, d_6^{16} 0.8175, n_D^{16} 1.50149, M. R. calcd., 87.86, M. R. found, 88.74, dehydrates to *7-phenyl-6-tridecene*, b_8 153–4, d_{15}^{15} 0.8774, n_D^{18} 1.49810, M. R. calcd., 85.87, M. R. found, 86.26. On ozonolysis this gives caproic aldehyde and Ph hexyl ketone. It hydrogenates to give *7-phenyltridecane*, b_{20} 183–4°, d_{20}^{20} 0.8723, d_{50}^{50}

0.8604, n^{25}_D 1.49307, M. R. calcd., 66.34, M. R. found, 66.68, η_{20} 8.651, η_{60} 5.618, a thick, glassy substance at −78°. Thus, as the branching of the chain increases, the solidification point falls and the viscosity index changes very slightly. H. M. Leicester



Polymerization ability of substituted styrenes in relation to their structure. II. P. P. Shorygin and N. V. Shorygina. *J. Gen. Chem.* (U. S. S. R.) 9, 845–54 (1939); cf. *C. A.* 29, 6885⁶.—*p*-Bromotoluene, obtained from *p*-toluidine, was oxidized with CrO_2Cl_2 in CS_2 to BrC_6H_4CHO, which was condensed with MeMgI in Et_2O to give *p*-$MeCH(OH)C_6H_4Br$ (I), b_{20} 145°, d^{17} 1.379, n^{17}_D 1.562. *p*-$BrC_6H_4CH:CH_2$, b_{20} 102–4°, d^{18} 1.408, n^{18}_D 1.586, was obtained from I on heating with $KHSO_4$ at 130–40° for 4 hrs. *o*-$BrC_6H_4CH(OH)Me$, obtained in a similar way from *o*-$MeC_6H_4NH_2$, b_{15} 128°, d^{17} 1.4008, n^{17}_D 1.566. *o*-$BrC_6H_4CH:CH_2$, b_{22} 102–4°, d^{16} 1.409, n^{16}_D 1.592. *p*-$MeOC_6H_4CH:CH_2$, b_{20} 104°, d^{17} 1.0015, n^{17}_D 1.560. *o*-$MeOC_6H_4CH:CH_2$, b_{15} 85°, d^{16} 1.009, n^{16}_D 1.556. *p*-$H_2NC_6H_4CH:CH_2$, b_{10} 125–7°, d^{14} 1.0216, n^{14}_D 1.619. *o*-$H_2NC_6H_4CH:CH_2$, b_{12} 102–4°, d^{15} 1.015, n^{15}_D 1.608. $PhCBr:CH_2$, b_6 67–8°, d^{17} 1.425, n^{17}_D 1.591. $PhCH:CHBr$, b_{20} 108°, d^{18} 1.462, n^{18}_D 1.605. $C_6H_{11}CH:CH_2$, b. 126–8°, d^{17} 0.8186, n^{17}_D 1.4475. $C_6H_{13}CH:CH_2$, b. 122–3°, d^{17} 0.7271, n^{17}_D 1.4165. Ph_2 (II) was nitrated by means of HNO_3 in AcOH or of N_2O_4. In the latter case 50 g. II was treated with 200 g. N_2O_4 in the cold and the mixt. of *o*- and *p*-$O_2NC_6H_4Ph$ (III) sepd. by fractional crystn. III, m. 112–13°, was obtained in a yield of 45%. *p*-$H_2NC_6H_4Ph$, from III on reduction with Sn and HCl, yielded *p*-IC_6H_4Ph, m. 110–11°, b_4 180°, which gave PhC_6H_4MgI. The latter compd. was condensed with ethylene oxide in C_6H_6 to yield *p*-$HOCH_2CH_2C_6H_4Ph$, m. 93–4°. The study of the thermal polymerization of substituted styrenes at 100° and 170° in the absence of catalysts revealed that substituents in the α- and β-positions exerted a hindering influence on the polymerization ability. This ability decreases with increasing mol. wt. and length of the aromatic residue attached to the ethylene mol. The polymerization is accelerated at elevated temp. but simultaneously the degree of polymerization is decreased. Gertrude Berend

Decomposition of some iodonium salts. Reactions with mercury, tellurium and antimony. R. B. Sandin, F. T. McClure and F. Irwin. *J. Am. Chem. Soc.* 61, 2944–6 (1939). Lucas, *et al.* (*C. A.* 30, 1753⁷), have suggested that the decompn. of $(o\text{-}MeC_6H_4)_2I_2$ at 155° to give *o*-MeC_6H_4I involves as an intermediate a pos.-charged *o*-MeC_6H_4 ion in which the pos. charge is carried by a C atom; this ion then combines with the neg. ion of the iodonium salt to form a mol. of *o*-MeC_6H_4I. To account for the following reactions, it is suggested that at least a part of the iodonium salt decomps. by way of a non-ionic mechanism. Ph_2ICl and $(p\text{-}MeC_6H_4)_2ICl$ with Hg in boiling PrOH give PhHgCl and *p*-MeC_6H_4HgCl; with Te they give Ph_2Te and $(p\text{-}MeC_6H_4)_2Te$; heating Ph_2ICl and finely divided Te gives Ph_2TeCl_2. Diphenyliodonium sulfide decomps. at room temp. in the presence of Te and Sb to give Ph_2Te and triphenylstibine sulfide.
C. J. West

Nitration of diphenyliodonium nitrate. R. B. Sandin, F. T. McClure and F. Irwin. *J. Am. Chem. Soc.* 61, 3061–3 (1939).—Ph_2INO_3 with HNO_3-H_2SO_4 gives about 18.5% of para nitration (thermal analysis); at least 10% of the reaction mixt. can be isolated as *p*-$IC_6H_4NO_2$ and by taking into consideration the solvent effect of the EtOH, the amt. of para nitration can be shown to be at least 14%. This confirms the work of Challenger and Rothstein (*C. A.* 28, 6429⁸). G. J. West

Cleavage of quaternary ammonium salts by sodium sulfide. II. H. R. Snyder and J. C. Speck. *J. Am. Chem. Soc.* 61, 2895–7 (1939); cf. *C. A.* 33, 3345⁷.—It has been shown that $Me_2Ph(PhCH_2)NCl$ (I) with Na_2S gives $(PhCH_2)_2S$ and $PhNMe_2$. Other groups than $PhCH_2$ attached to the N atom play an important part in the cleavage. $PhCH_2NMe_3Cl$ (II) is not affected under conditions which bring about rapid decompn. of I. $PhCH_2Cl$ and *N,N*-diethylcyclohexylamine give *benzyldicyclohexyldiethylammonium chloride*, m. 179° (decompn.); this resists the action of aq. Na_2S. $PhNMe_3I$ and Bu_4NI (III) also failed to undergo cleavage and $(PhCH_2)_2Et_2NI$ was only very slightly cleaved. Benzylpyridinium chloride undergoes rapid scission to C_6H_5N and $(PhCH_2)_2S$. It appears, therefore, that the linkage between an alkyl group and the N atom is attached to or is a part of an aromatic system. *Allyldimethylphenylammonium bromide*, very hygroscopic, is rapidly cleaved by aq. Na_2S. II gives 50% of cleavage products when the reaction is carried out at 135–50° (in diethylene glycol); III is cleaved to the extent of at least 75% at 175°. I and $Na_2S_2O_4$, refluxed 15 min., give 58% of $PhNMe_2$ and 60% of $(PhCH_2NPhMe_2)(SO_3SCH_2Ph)$. C. J. West

Exchange reactions in deuterioalcohol. II. Weldon G. Brown, M. S. Kharasch and W. R. Sprowls. *J. Org. Chem.* 4, 442–55 (1939); cf. *C. A.* 31, 5755⁶.—In the previous paper, the mechanism of the exchange reactions between EtOD and $PhNMe_2$ (I) was discussed and it was pointed out that while the normal reaction of I with a dil. acid would be the formation of an NH^+ salt, this salt would not necessarily be an intermediate in the exchange reaction which would give rise to tautomeric forms. The free base as a resonance hybrid may accept a proton at any one of the 2 *o*-positions or the *p*-position. The products formed would be tautomeric forms and it will be evident that dissoen. of the quinoid forms of the salt will

give rise to H exchange. The 2 hypotheses could be experimentally distinguished if the influence of the base strength on the H exchange is considered. If the normal salt is an intermediate in the exchange reaction, then structural changes which decrease the basicity of the mol. should also inhibit the exchange reaction. If, however, the structural change decreases the basic strength mainly by increasing the no. of the stability of the zwitterion resonance forms, the exchange reaction should be favored. Ph_2N (II) therefore should have the same rate of H exchange as I in spite of the enormous difference in base strength since substitution of Ph for Me groups will increase the no. of points at which a proton may become attached. The exptl. results obtained from I, Ph_2NH (III), II, *o*-, *m*- and *p*-$NO_2C_6H_4NMe_2$ (IV, V and VI) and *m*-$BrC_6H_4NMe_2$ (VII) are found, as a whole, to be in accordance with the hypothesis that quinoid forms of the salts act as intermediates. Repetition of the expts. with I shows that in an acid soln. 3 H atoms are involved in the exchange reaction while in neutral or alk. solns. no appreciable exchange takes place. II exchanges 1 H atom, presumably the *N*-H, in the absence of acid and 6 H atoms in acid soln. The most probable value for the exchange no. is 7 and it is likely that the *o*- and *p*-positions in each ring and the *N*-H are involved. III behaves similarly; the observed exchange no. is 7.9, corresponding to the exchange of 9 H atoms. IV, V and VI show very striking differences in the lability of the H in the ring. Assuming that only the H in *o*- and *p*-positions to the Me_2N group is labile, the theoretical limit for the no. of exchangeable H atoms would be 2 for IV and VI and 3 for V. Actually IV shows no exchange at all under the exptl. conditions applied, while in VI the exchange is almost complete in acid soln. and in V the value lies under the theoretical value and V can therefore be regarded as intermediate in reactivity. In neutral and alk. solns. V and VI show almost no exchange. VII in acid soln. has an exchange no. of 2. The next group investigated comprises fluorene (VIII), 9-fluorenol (IX), 9-methoxyfluorene (X), 9-aminofluorene (XI) and 9-dimethylaminofluorene (XII). Of these, VIII in alk. soln. exchanges 2 H atoms, IX in

neutral soln. exchanges the H of the OH group, in alk. soln. a 2nd H, presumably that at the 9-position, while in acid soln. **IX** is decompd. **X** does not exchange in alk. soln. and decomps. in acid soln. **XI** and **XII** decomp. in acid and alk. solns. In connection with earlier expts., acetophenone (**XIII**), acetomesitylene (**XIV**), quinaldine (**XV**) and styrene (**XVI**) are retested and it is found that **XIII** has an exchange no. of 2.15 in alk. and 1.6 in acid soln., **XIV** 1.2 in neutral, 2.19 in alk. and 2.1 in acid soln. With **XV** and **XVI** the earlier results are confirmed. A tentative explanation for these exchange reactions is advanced. F. E. Brauns

Thioacyl derivatives of primary amines. (The synthesis of acyclic carbocyanine dyes.) I. L. Knunyants and L. V. Razvadovskaya. *J. Gen. Chem.* (U. S. S. R.) **9**, 557–70 (1939). $PhCH_2NHAc$ heated with P_2S_5 in C_6H_5 gives *55% thioacetylbenzylamine*, m. 71°. When this is refluxed with MeI it gives 100% *thioacetylbenzylamine S-Me ether-HI*, m. 104–6°, from which KOH liberates 64% of the free *base*, b_4 115 8°, d^{28} 1.0575, n_D^{28} 1.5652, M. R. calcd., 55.141, M. R. found, 55.0. When this is mixed with MeI at −10° for 2 hrs. and then allowed to stand at room temp. for 2.5 days, it gives 38% of *thioacetylbenzylamine S-Me ether-MeI* (I), m. 120°. By a similar series of reactions starting from MeNHAc are obtained 43% *thioacetylmethylamine*, m. 58°, 100% *thioacetylmethylamine S-Me ether-HI*, m. 119°, 69.5% of its free *base*, b_{748} 132–3°, d^{20} 0.9459, n_D^{20} 1.492, and the *methiodide* (II), a hygroscopic solid. I and II condense with $HC(OEt)_3$ (III), anilinomalonaldehyde anil (IV), anilinoglutaconaldehyde anil (V) and $Me_2NC_6H_4CHO$ (VI) in the presence of acetates to give acyclic carbocyanine dyes which are similar to the analogous dyes prepd. from thiazole compds. The compd. from I and III is yellow and has an absorption max. at 420 mμ. I and IV give a red dye, absorption max. 580 mμ, sensitizing max. for an AgBr emulsion at 610 mμ. I and V give a blue-green dye, absorption max. 630 mμ, sensitizing max. 676 mμ. This normally changes to a violet dye, absorption max. 548 mμ, sensitizing max. 580 mμ, but sometimes, for unexplained reasons, this change does not occur. I and VI give an orange-red dye, absorption max. 500 mμ. Similarly, II and III give a yellow dye, absorption max. 400 mμ; II and IV give a clear red dye, absorption max. 560 mμ, sensitizing max. 580 mμ, and II and VI give a clear orange-red dye with absorption max. at 475 mμ. H. M. Leicester

Preparation of diazo compounds by means of organometallic compounds. J. G. Makarova and A. N. Nesmeyanov. *J. Gen. Chem.* (U. S. S. R.) **9**, 771–9(1939).—Based on the assumption that the reaction mechanism between N_2O_3 (I) and organometallic compds. proceeds with the dissocn. products of I, $I \rightarrow N_2O_4$ (II) + 2NO (III) according to the equations: $Ph_2M + 2II \rightarrow 2PhNO + M(NO_3)_2$ and $PhNO + 2III \rightarrow PhN_2NO_3$ (IV), expts. were carried out with I and III simultaneously and the following organometallic compds.: Ph_2Hg, Ph_4Sn, Ph_3SnCl, Ph_2SnCl_2, $PhSnCl_3$, Ph_4Pb, Ph_3PbCl and Ph_3Bi. The yields of IV were 85%, 40%, 48%, 49%, 80%, quant., 50%, 54%, resp., as compared with 23%, not investigated, 8%, 5%, 10%, 24%, 18%, 10%, resp., when I was used alone. Ph_2TiCl reacts with I with the formation of 8% IV. $PhMgBr$ (V) yields 15% IV on reaction with I. When 1 mol. $ZnCl_2$ is added to 2 mols V, the yield is increased to 20%. About the same increase is observed after the addn. of $CdBr_2$. In the 2 latter cases the simultaneous addn. of III did not increase the yield. From the reaction products of Ph_2Zn with I + III, and of PhLi, Ph_3As and Ph_3Sb, resp., with I, phenyldiazonium compds. could not be isolated. Ph_4Si and Ph_2PbCl_2 did not react with I. Gertrude Berend

Alleged cis-trans isomerism of α- and β-*p*-azophenol. W. M. Lauer, H. P. Klug and S. A. Harrison. *J. Am. Chem. Soc.* **61**, 2775–9(1939).—Willstatter and Benz (*C. A.* **1**, 302) reported the existence of cis-trans isomeric forms of *p*-azophenol (I); this view was supposed to be supported by the study of the absorption spectra (Hantzsch, *C. A.* **4**, 3234) and by its behavior on nitration and bromination (Robertson, *C. A.* **7**, 3751); more recently, Dostrovsky and Le Fèvre (*C. A.* **33**, 5248[3]) found that the dipole moments were identical and this, with the work reported below, shows that the so-called α- and β-forms of I are identical. Hydrated I gives anhyd. I which exists in 2 solid modifications, brick-red (II) and green (III). The transformation of the metastable II to III is subject to various influences (e. g., impurities) which were not investigated. X-ray diffraction studies of the α- and β-forms prepd. according to W. and B. showed that the hydrated varieties (IV) are identical, that the II prepd from them are identical but different from III and IV, and that III from the 2 sources are identical but have a different crystal structure from II. A study of the rise in b. p. on addn. of 1 compd. to the satd. soln. of the other showed that the α- and β-forms, as usually prepd. and purified, are not pure. The pure α-form, prepd. by chromatographing an AcOEt soln., gives no rise in b. p. when added to the β-form in Et_2O. Polarographic studies showed that both forms of I give the same cathodic or anodic waves; I is reduced at pH 5.75 and oxidized at pH 9.2. Nitration of either form of II gives the same di-NO_2 deriv. (V), yellow, m. 235–6°; V yields a *di-Br deriv.*, m. 281–2°. The tetra-NO_2 deriv. results from V and fuming HNO_3 at 0°. Both forms of I give the same *tetra-Br deriv.*, m. 273–4°; its *diacetate* m. 263–4° and its *dibenzoate* m. 297–8°. C. J. West

The reaction between triphenylbenzylphosphonium bromide and metallic sodium. L. N. Parfent'ev and A. A. Shamshurin. *J. Gen. Chem.* (U. S. S. R.) **9**, 865–7(1939).—Dry $Ph_3(PhCH_2)PBr$ (I), obtained in almost quant. yield from Ph_3P and $PhCH_2Br$ in toluene, was warmed (8.19 g.) with 0.43 g. Na powder in 250 ml. ether for 2 days while stirring, after which time moist air was introduced into the reaction mixt. for 4 hrs. while stirring. The ether soln. was sucked off, the residue was washed 3 times with fresh ether and then filtered off. The solid mixt. was treated with alc. whereby 1.920 g. I was extd. The residue consisted of 0.6721 g. NaBr. The ether soln. contained 2.022 g. Ph_3PO, m. 150–1°, and toluene. These results indicate that $Ph_2P\cdot CHPh$ is the primary reaction product from I and Na. G. B.

Reaction of diphenylmercury with organic monobasic acids. M. M. Kotou. *J. Gen. Chem.* (U. S. S. R.) **9**, 912–16(1939); cf. *C. A.* **33**, 4969[6].—Ph_2Hg was found to react with org. monobasic acids, according to the equation $Ph_2Hg + RCO_2H \rightarrow C_6H_6 + RCO_2HgPh$. HCO_2HgPh, m. 135–8° (decompn.). AcOHgPh, m. 147°. $EtCO_2HgPh$, m. 80–1°. $MeCH(OH)CO_2HgPh$, m. 151–5°. $PrCO_2HgPh$, m. 91°. $EtCH(OH)CO_2HgPh$, m. 159°. $C_{11}H_{11}CO_2HgPh$, m. 82–3°. $C_{17}H_{35}CO_2HgPh$, m. 90–2°. BzOHgPh, m. 97–8°. $C_6H_4(OH)CO_2HgPh$ (phenylmercuric salicylate), does not melt 200°. Gertrude Berend

Purification of *p*-acetaminobenzenesulfonyl chloride. L. H. Pence and H. C. Winter. *J. Am. Chem. Soc.* **61**, 2977–8(1939).—The crude *p*-$AcNHC_6H_4SO_2Cl$ (I) from 67.5 g. PhNHAc is dissolved in 1000 cc. Et_2O and washed with H_2O until free from sulfates; the Et_2O soln. is dried over Na_2SO_4 for 1 hr., concd. to 300 cc. and 1000 cc. C_6H_6 is added; after cooling, the filtered ppt. is washed with 200 cc. C_6H_6, giving 70 g. pure I, m. 149°. The m. p. did not change in 7 months. C. J. W.

Sulfanilamide derivatives. IV. N^1,N^4-Diacylsulfanilamides and N^1-acylsulfanilamides. M. L. Crossley, E. H. Northey and Martin E. Hultquist. *J. Am. Chem. Soc.* **61**, 2950–5(1939); cf. *C. A.* **32**, 8382[6].—The most generally applicable method for the synthesis of N^1-acylsulfanilamides and that giving the best yield consists in the use of acyl halides and N^4-acetylsulfanilamide (I) in C_5H_5N, followed by alk. hydrolysis, the yield based on the halide averaging 60%. Acid anhydrides may also be used, Ac_2O giving 60% of the di-Ac deriv., hydrolysis of which gives 32% of the N^1-Ac deriv. (soly. in H_2O at room temp., 0.9%). The N^1-Na deriv. of I, prepd. from I and NaOH with recrystn. from H_2O and dehydration *in vacuo* at 60–70°, was used in earlier work but was discarded in favor of the C_5H_5N method. Dry fusion of

I and acyl halides led in general to decompn. products together with the desired N^1-acyl derivs. I and BzCl in PhMe, refluxed 20 hrs., give 40% of the N^1-Bz deriv. Attempts to prep. N^1-alkyl-N^1-acylsulfanilamides by hydrolysis of the corresponding N^4-Ac derivs. resulted in complete hydrolysis of the N^1-Ac deriv. Such derivs. were prepd. by acylating N-alkylnitrobenzenesulfonamides and reducing with Fe and AcOH in PhMe. In the series of derivs. of fatty acids, the lower members were moderately H_2O-sol.; on ascending the series, the H_2O soly. decreased and the soly. in fat solvents increased; H_2O soly. of derivs. having chains of 12 C or more was less than 0.001 g./100 cc. All of the derivs. in which a H remained on the amide N formed very sol. Na salts, which were neutral for the lower members of the series but became increasingly alk. for the higher members. All of these compds. could be titrated quantitatively to a phenolphthalein end-point, however, while sulfanilamide itself cannot be so titrated, since its Na salt is highly hydrolyzed at this pH. In general, the derivs. could be hydrolyzed quantitatively to the org. acid and the amide (or sulfanilic acid) by boiling with alc. HCl or more rapidly by heating to 180–200° with 65% H_2SO_4. The lower members of the series could be titrated quantitatively by diazotization of the N^4-NH_2 group. Alkylation of the N^1-N gave derivs. which no longer formed salts with cations; these had increased soly. in org. solvents. These derivs. were sensitive to hydrolytic agents and in this resembled the N^1-alkyldisulfanilamides (*C. A.* **32**, 8382[4]). In the tables of data qual. data are given for the solv. and the cryst. form. *N^1-Acylsulfanilamides:* Ac (II) m. 182–4°, *propionyl* m. 131–5°, *butyryl* m. 125.4–6.6°, *isobutyryl* m. 198.5–200°, *2-ethylbutyryl* m. 189–93.5°, *hexanoyl* m. 129.2–9.9°, *heptanoyl* m. 121.8–3.6°, *2-ethylhexanoyl* m. 165.5–8°, *octanoyl* m. 101–3°, *decanoyl* m. 119–21°, *hendecanoyl* m. 112.5–14.5°, *dodecanoyl* (III) m. 127–8.5°, *tetradecanoyl* m. 113.5–17.7°, *octadecanoyl* m. 98–102°, *9-octadecenoyl*, amorphous, *hexahydrobenzoyl* m. 195.5–200°, *chaulmoogryl* m. 97.9–9°, *Bz* m. 181.2–2.3°, *p-nitrobenzoyl* m. 235–40°, *p-aminobenzoyl* m. 197.8–9°, *hydrocinnamoyl* m. 160.3–1.5°, *cinnamoyl* m. 130–3° and then 174–5°, *1'-carboxybenzoyl* m. above 225° (decompn.), *mandelyl* m. 192.5–4.5° (decompn.), *diphenylacetyl* m. 210.5–12°, *furoyl* m. 191.5–2°, *2-phenylcinchoninyl* m. 305–10°, *nicotinyl* m. 256–7.5°, *3-hydroxy-2-naphthoyl* m. 245–50°. *N^1-Acetylmetanilamide*, m. 153.5–5.5°; *tetradecanoyl analog*, m. 113.5–14.2°. *N^1-Methyl-N^1-dodecanoylsulfanilamide*, m. 59.3–60.5°. *N^1-Acyl derivs. of N^1-acetylsulfanilamides:* Ac m. 253.5–5°, *propionyl* m. 242.5–4.3°, *isobutyryl* m. 247–8°, *butyryl* 238.2–40°, *isovaleryl* m. 215–17.5°, *2-ethylbutyryl* m. 270–3°, *hexanoyl* m. 191–3°, *heptanoyl* m. 205–7.5°, *2-ethylhexanoyl* (IV), m. 214–15.6°, *octanoyl* m. 195–7.6°, *decanoyl* m. 143.2–4.8°, *hendecanoyl* m. 153.2–5°, *dodecanoyl* m. 130–6°, *tetradecanoyl* m. 144.2–5°, *9-octadecanoyl* m. 131–5°, *chaulmoogryl*, *Bz* m. 280–5°, *hexahydrobenzoyl* m. 210–22°, *p-nitrobenzoyl* m. 270–2°, *p-aminobenzoyl* m. 260–3°, *hydrocinnamoyl* m. 160° and then 202.8–5.4°, *cinnamoyl* m. 228–9.5°, *diphenylacetyl* m. 248.5–51°, *furoyl* m. 240.5–41.5°, *2-phenylcinchoninyl* m. 166–70°, *nicotinyl* m. 295–300°. *N^1,N^4-Didodecanoylsulfanilamide*, m. 144–5°, *N^1-dodecanoyl-N^4-(N-acetylsulfanilyl)sulfanilamide*, m. 120° and then 150–2°; *N^1-dodecanoyl-N^4-sulfanilylsulfanilamide*, m. 102–4°. The *Na salt* (with 1 mole H_2O), NH_4 and Et_2NH_2 salts of II and the Ag, Hg'' and Ca salts of III and the Na and Mg salts of IV were prepd. and analyzed. Preliminary *pharmacol. results* indicate that III is effective in mice against infections by β-hemolytic streptococci and arrests the spread of tuberculous infections in cavies. C. J. West

Chemistry and chemotherapy of 4,4'-diaminodiphenyl sulfone, 4-amino-4'-hydroxydiphenyl sulfone and related compounds. G. W. Raiziss, L. W. Clemence, M. Severac and J. C. Moetsch. *J. Am. Chem. Soc.* **61**, 2763–5 (1939).—*p*-$ClC_6H_4NO_2$ and Na_2S in H_2O, refluxed 23 hrs., give 80% of 4-$O_2NC_6H_4SC_6H_4NH_2$-4 (I), orange-yellow, m. 145°; reduction with Sn in HCl (1:1) gives 80% of $(4\text{-}H_2NC_6H_4)_2S$, m. 108°; di-Ac deriv., m. 223–4°, oxidation of which gives 63% of $(4\text{-}H_2NC_6H_4)_2SO_2$ (II), pale yellow, m. 285°; the free di-NH_2 deriv. m. 175°. I gives an Ac deriv., pale yellow, m. 198°; oxidation with $K_2Cr_2O_7$ gives 81% of *4-nitro-4'-acetylaminodiphenyl sulfone*, cream, m. 229–30°; reduction with $SnCl_2$ in EtOH gives 66% of the *4-amino deriv.*, pale yellow, m. 242–3°; the diazo reaction yields 66% of *4-amino-4'-hydroxydiphenyl sulfone* (III), m. 193–4°; *4-acetylamino deriv.*, m. 274–5°; *4-acetylamino-4'-acetoxydiphenyl sulfone*, m. 171–2°. II is superior, while III and the Ac derivs. are about equal to sulfanilamide in their therapeutic effect. C. J. West

The Raschig process for the preparation of phenol. W. Mathes. *Angew. Chem.* **52**, 591–2(1939).—The process is represented by the following equations: $C_6H_6 + HCl + 0.5O_2 = PhCl + H_2O$, and $PhCl + H_2O = PhOH + HCl$. The process works continuously, without pressure and catalytically. The catalyst developed consists of an activated Al hydroxide in combination with Cu salts and permits operation at about 250° and with 15–20% aq. HCl. The sapon. of PhCl is carried out at 450–500°. Process yields are such that large-scale operation is economically sound. Karl Kammermeyer

Binary systems with hydrazine. III. Thermal analysis of the system hydrazine-phenol. V. I. Semishin. *J. Gen. Chem.* (U. S. S. R.) **9**, 788–91(1939); cf. *C. A.* **33**, 4597.—The system hydrazine–phenol was investigated by means of thermal analysis, and the presence of a new compd. $N_2H_4 \cdot 2C_6H_5OH$, m. 63.6° (partial decompn.), was thus established. The compds. $N_2H_4 \cdot C_6H_5OH$ (cf. Curtius and Thun, *J. prakt. Chem.* **4**, 190(1891)) and $N_2H_4 \cdot 4C_6H_5OH$ (cf. Cazaneuve and Moreau, *Compt. rend.* **129**, 1255(1899)) could not be detected by this method. Gertrude Berend

Molecular compounds of picric acid. Mme. R. Râşcanu. *Ann. sci. univ. Jassy*, Pt. I, **25**, 395–423(1939)(in French).—A review, with 58 references, of work on the constitution of picrates. Table of all those prepd. to date, including complex combinations and metallic salts of picric acid. The following *picrates*, all yellow, were made (1:1 combination): *dimethylaniline*, m. 157–8° (turns green in several months; red, brown and green forms also prepd.); *diethylaniline*, m. 139–40°; *benzalaniline*, m. 159°; *benzalaminoantipyrine*, m. 160°; *ethylbenzylaniline*, m. 120–1°; *benzidine*, m. 190–2°. Work on other colored forms and complex combinations to follow. P. M. Apfelbaum

Rearrangement of phenyl allyl ethers. III. Synthesis of α-(*o*-methoxyphenyl)propionic acid. Walter M. Lauer and Louis I. Hansen. *J. Am. Chem. Soc.* **61**, 3039–43 (1939); cf. *C. A.* **30**, 6722[1].—It has been shown that $PhOCH_2CH_2 \cdot CHEt$ is rearranged into *o*-$HOC_6H_4CHEt\text{-}CH \cdot CH_2$ and *o*-$HOC_6H_4CHMeCH\ CHMe$ (I), the structure of which was proven by conversion into *o*-$MeOC_6H_4\text{-}CHMeCO_2H$ (II). Two syntheses of II are reported. *o*-$MeOC_6H_4CH_2OH$ was converted through the chloride and cyanide to *o*-$MeOC_6H_4CH_2CO_2Et$, m. 123–4° (Et ester (III), b_{13} 137–8°). Reaction of $(CO_2Et)_2$ and III with EtONa in EtOH and heating the Et *o*-methoxyphenyloxalacetate at 15° up to 175° gives *di-Et o-methoxyphenylmalonate* (IV), $b_{4.5}$ 162–4°. Reaction of MeI with the Na deriv. of IV and removal of the unchanged IV by fractional hydrolysis with 4.5% KOH gives *di-Et o-methoxyphenylmethylmalonate* (V), $b_{2.5}$ 150–1°; hydrolysis with 10% KOH gives the *free acid*, m. 148.5–9° (decompn.), which gives II on refluxing in xylene for 2 hrs. IV and EtI give *di-Et o-methoxyphenylethylmalonate*, m. 66.7°; hydrolysis and decarboxylation give *α-(o-methoxyphenyl)butyric acid*, b_{10} 165–6°, m. 56.7°. The *p-MeO isomer* of V $b_{3.5}$ 160–1°, n_D^{25} 1.4990; the free *acid* m. 149.5–50°. In the 2nd synthesis of II 4-methylcoumarin was converted to *o*-$MeC_6H_4CMe \cdot CHCO_2H$, which was reduced by 4% Na-Hg in H_2O at 50° to *o-methoxy-β-methylhydrocinnamic acid*, b_9 172°, m. 49–50°; *Et ester*, b_9 153–4°; PhMgBr gives the *carbinol*, *o*-$MeOC_6H_4CH\text{-}MeCH_2C(OH)Ph_2$, which could not be crystd.; refluxing with Ac_2O gives *o*-$MeC_6H_4CHMeCH\ CPh_2$, a yellow oil, which is oxidized by CrO_3 in AcOH to II. These syntheses prove the structure of I. IV. **An examination of the py-**

rolysis product of phenyl allyl ether for evidence of para rearrangement. Walter M. Lauer and Robert M. Leekley. *Ibid.* 3042-3.—*o-* and *p*-Allylphenols are not easy to sep. but the corresponding HOC_6H_4CHO are easily sepd. since the *o*-isomer forms a Cu deriv. but the *p*-deriv. does not; with this test 70 mg. of the *p*-isomer was recovered from a mixt. of 10 g. of the *o*- and 100 mg. of the *p*-isomers. The rearrangement product obtained by the pyrolysis of Ph allyl ether was converted to the corresponding HOC_6H_4CHO by isomerization with KOH followed by ozonolysis; no trace of *p*-HOC_6H_4CHO could be found. A sample of *o*-allylphenol prepd. by decarboxylation of 3-allyl-4-hydroxybenzoic acid was compared with one prepd. by rearrangement of the ether; there were no significant differences in *n* or in m. ps. of the crude phenylurethans of the 2 products. **V. The isomeric ethyl *p*-(α- and γ-propylallyloxy)benzoates.** *Ibid.* 3043-7.—*p*-$HOC_6H_4CO_2Et$ (I) in Me_2CO with 3-chloro-1-hexene and K_2CO_3, refluxed 12 hrs., gives a mixt. of esters (about 75% of IV), which $b_{0.05}$ 105-6°; hydrolysis and crystn. from C_6H_6 and petr. ether give *p*-(γ-*propylallyloxy*)-*benzoic acid* (II), m. 138.9°, and from the mother liquor (crystn. from MeOH) the *α-isomer* (III), m. 76.7°; if the melted III is chilled, it gives an allotropic form, m. 35-8°, which can be converted to the higher-melting form. III with O_3 gives HCHO. *Et ester* (IV) of III, $b_{0.5}$ 95.7°, n_D^{25} 1.5130. Pyrolysis of IV at 220-46° and 40 mm. gives *Et 3-*(γ-*propylallyl*)-*4-hydroxybenzoate* (V), m. 75-6.5°; this does not reduce $Hg(OAc)_2$ in AcOH. V with Me_2SO_4 and MeONa in MeOH gives the *4-MeO deriv.* (VI) of V, m. 107-8°; O_3 gives PrCHO. Catalytic reduction of VI gives *3-hexyl-4-methoxybenzoic acid*, m. 113.5-14°. Heating V with KOH gives *3-*(*1-hexenyl*)-*4-hydroxybenzoic acid*, m. 134-5°, which gives a ppt. with $Hg(OAc)_2$ in AcOH. I and 1-chloro-2-hexene with Me_2CO contg. K_2CO_3 give the *Et ester* (VII) of II, $b_{0.2}$ 115-16°, m. 14.1°, n_D^{25} 1.5197; hydrolysis gives II, which is reduced to *p-hexyloxybenzoic acid*, m. 105.5-7°; this was also prepd. from I and hexyl bromide with EtONa in EtOH. Pyrolysis of VII gives a mixt. of *Et 3-*(α-*propylallyl*)-*4-hydroxybenzoate* (VIII) and Et 3-(α-methyl-γ-ethylallyl)-4-hydroxybenzoate (IX), b_5 183-8°, n_D^{25} 1.5367; O_3 gives a mixt. of HCHO and EtCHO. Methylation of the mixt. of esters with Me_2SO_4 and EtONa in EtOH and repeated crystn. from petr. ether gives *3-*(α-*propylallyl*)-*4-methoxybenzoic acid* (X), m. 142.5-3.5°, and *3-*(α-*methyl*-γ-*ethylallyl*)-*4-methoxybenzoic acid* (XI), m. 113-14°. XI and O_3 give EtCHO; X gives HCHO. Catalytic reduction of XI gives *3-*(*1-methylamyl*)-*4-methoxybenzoic acid*, m. 125-6°, and X gives *3-*(*1-ethylbutyl*)-*4-methoxybenzoic acid*, m. 145-6°. Hydrolysis of the rearrangement product of VII gives VIII, m. 133-4°; the more sol. IX could not be isolated. The formation of IX constitutes an addnl. example of an abnormal Ph allyl ether rearrangement and supplies evidence for the view that, in an abnormal rearrangement, the aromatic residue becomes attached to the β-C atom, whereas the normal rearrangement leads to a transposition of the aromatic residue to the γ-C atom. **VI. The isomeric ethyl *p*-(α- and γ-ethylallyloxy)benzoates.** W. M. Lauer and H. E. Ungnade. *Ibid.* 3047-9.—Et *p*-(α-ethylallyloxy)benzoate (I), heated at 200-36° and 40 mm., gives some 1,3-pentadiene (II) and *p*-$HOC_6H_4CO_2Et$ (II) and the normal rearrangement product, Et 3-(γ-ethylallyl)-4-hydroxybenzoate, whose *4-MeO deriv.* m. 117-17.5°; O_3 gives EtCHO. III (61.6 g.) and 40 g. 1-chloro-2-pentene in Me_2CO with K_2CO_3 gave 41 g. *Et p-*(γ-*ethylallyloxy*)-*benzoate* (IV), $b_{0.1}$ 108-9°, m. 34.1°; *acid* (V), m. 157-8°; reduction of V gives *p*-$AmOC_6H_4CO_2Et$; V with O_3 gives EtCHO. Pyrolysis of IV gives a mixt. of Et 3-(α-ethylallyl)-4-hydroxybenzoate (VI) and Et 3-(α,γ-dimethylallyl)-4-hydroxybenzoate (VII), with 13.3% of II; methylation of this mixt. gives only 1 pure product, the *MeO deriv.* of VI, m. 164.5-5.5°. The mixed methylation product gives HCHO and AcH with O_3, indicating the presence of VII. III (37.5 g.) and 23.5 g. 4-chloro-2-pentene give 16.5 g. of *Et p-*(α,γ-*dimethylallyloxy*)*benzoate* (VIII), $b_{0.1}$ 108-14°; the *acid* m. 131-2°. Pyrolysis of VIII at 40 mm. and 208-23° gives 58.5% of II and III; methylation of the rearrangement product, followed by hydrolysis, yields a product which upon crystn. shows the properties of a mixt.; O_3 gives AcH and a small quantity of HCHO. If ozonolysis can be relied upon, then it must be concluded that VIII also yields an abnormal as well as a normal rearrangement product.

C. J. West

Iodo derivatives of phenyl ether. II. Studies in orientation. R. Q. Brewster and H. S. Choguill. *J. Am. Chem. Soc.* **61**, 2702-4(1939); cf. *C. A.* **28**, 1674⁷.—This work was undertaken to obtain information on orientation in the Ph_2O series, the effect of the MeO group being studied. 4-$MeOC_6H_4OPh$ (I) gives 70% of the 3-NO_2 deriv. (II), but iodination gives *4-methoxy-4'-iododiphenyl ether* (III), m. 115°, which was also prepd. from the 4'-NH_2 deriv. by the Sandmeyer reaction. I (10 g.) and $AlCl_3$ give 75% of *p*-HOC_6H_4OPh, whose Bz deriv. m. 97°; III gives 4-$HOC_6H_4OC_6H_4I$-4', whose *Bz deriv.* m. 122°. Catalytic reduction of II gives *4-methoxy-3-aminodiphenyl ether* (IV), m. 70° (*Ac deriv.*, m. 148°); the Sandmeyer reaction gives the *3-I deriv.* (V), m. 76°; the *3-Br deriv.* (VI) b_{10} 182-7°, m. 55°. Bromination of III or iodination of VI gives *4-methoxy-3-bromo-4'-iododiphenyl ether*, m. 88°. Iodination of III or V or the application of the Sandmeyer reaction to VII gives *4-methoxy-3,4'-diiododiphenyl ether*, m. 101°. Iodination of II or nitration of III yields *4-methoxy-3-nitro-4'-iododiphenyl ether*, m. 92°; reduction with Fe in AcOH gives the *3-NH_2 deriv.* (VII), m. 85°. *o*-$ClC_6H_4NO_2$ and *p*-$MeOC_6H_4OH$ give *4-methoxy-2'-nitrodiphenyl ether* (VIII), m. 77°; *4'-I deriv.*, m. 70°; *4-methoxy-2'-amino-4'-iododiphenyl ether*, m. 102°. VIII on nitration yields *4-methoxy-2',3-dinitrodiphenyl ether*, m. 132°; the isomeric *2',4'-di-NO_2 deriv.*, m. 110°, results from 2,4-$(O_2N)_2$-C_6H_3Cl and *p*-HOC_6H_4OMe. *2-Methoxy-4'-iododiphenyl ether* (IX), b_{28} 228°; the *5-NO_2 deriv.* (X) m. 115°. 2-$MeOC_6H_4OC_6H_4NO_2$-4' and I give *2-methoxy-5-iodo-4'-nitrodiphenyl ether*, m. 109°, which also results from 4-$O_2NC_6H_4F$ and 5,2-I(MeO)C_6H_3OK. 2,5-MeO(O$_2$N)-$C_6H_3NO_2$ and PhOK give *2-methoxy-5-nitrodiphenyl ether*, m. 72° (Lea and Robinson, *C. A.* **20**, 1608, prepd. this by nitration of 2-$MeOC_6H_4OPh$ and considered it to be the 6-NO_2 deriv.); iodination yields X. The effect of the MeO group in these reactions is discussed.

C. J. West

Hydrogen bonding by S-H. VII. Aryl mercaptans. M. J. Copley, C. S. Marvel and Emanuel Ginsberg. *J. Am. Chem. Soc.* **61**, 3161-2(1939); cf. *C. A.* **33**, 6258⁸.—No heat of mixing was observed with heptyl mercaptan in $AcNMe_2$ (I), Et_2O (II), Me_2CO (III) or C_6H_6 (IV). PhSH: I 572 cal. per mole of soln. at 3° for equimol. mix.; II 173, III 150, IV 0. PhC:CH I 644, II 272, III 200, IV 0; $CHCl_3$ I 920, II 700, IV 0. These results afford evidence of H bonding to donor O and N atoms by PhSH but not by heptyl mercaptan. The failure of aryl mercaptans to show assocn. is a result of the weak donor ability of the S atom for H bonding and not from any lack of acceptor ability on the part of the H of the S-H link. It is pointed out that whenever a H is attached to another atom by a sufficiently ionic link, H bonding is possible.

C. J. West

Preparation of seleno-*o*- and *m*-cresols. Duncan G. Foster. *J. Am. Chem. Soc.* **61**, 2972-3(1939).—*Seleno-o-cresol*, b_{26} 99°, results in 41% yield from *o*-MeC_6H_4MgCl and Se in a current of H; the *m-isomer*, b_{16} 89°, results in 47% yield; these rapidly turn yellow in air and were analyzed as the corresponding acids, $MeC_6H_4SeO_2H$, m. 123-5° (*o*) and 118-19° (*p*).

C. J. West

Use of triiodophenyl ethers for the identification of alkyl halides. Robert D. Drew and Julian M. Sturtevant. *J. Am. Chem. Soc.* **61**, 2666(1939).—2,4,6-$I_3C_6H_2OH$ (5 g.) and an equiv. amt. of the alkyl halide with 22 cc. EtONa (12.3 g. Na in 1 l. abs. EtOH) are refluxed 30 min. or until a ppt. of NaX is formed. The soln. is filtered, cooled, and dild. with H_2O, the ppt. being recrystd. from EtOH. *2,4,6-Triiodophenyl ethers.*—Me m. 98.5° (m. ps. cor.), Et m. 83.5°, Pr m. 82°, *iso-Pr* m. 43°, *Bu* (m.

66°, *iso-Bu* m. 48°, *Am* m. 47°, *hexyl* m. 44.5°, benzyl m. 122.5°, *β-phenylethyl* m. 88°, *γ-phenylpropyl* m. 63.5°, *p-nitrobenzyl* m. 207.5°, *hydroxyethylene* m. 137.5°; $BrCH_2CO_2Et$ gives a compd. m. 124° and $MeCHBrCO_2Et$ a *compd.* m. 80.5°. In all cases where the m. ps. are close together a mixed m. p. shows a large depression.
C. J. West

Iodination of organic compounds with the aid of oxidizing agents. T. D. Aldoshin and V. S. Chalykh'yan. *J. Gen. Chem.* (U. S. S. R.) 9, 748-52(1939).—Iodination of phenol and phenol derivs. by means of free and bound I has been carried out in the presence of KClO, H_2O_2, HNO_3, $KMnO_4$, K_2CrO_4, AcNHCl, *N,N*-dichloropentamethylenetetramine, and chloroamine B and T. To a mixt. of 0.0005 mol. of a 0.1 *N* soln. of the compd. to be iodized and the corresponding amt. of 0.1 *N* alc. I is added the equiv. amt. of the oxidizing agent in 0.1 *M* soln. The reaction proceeds according to the equation $O_2 + 2I_2 + 4RH \rightarrow 4RI.2H_2O$. The amt. of absorbed I 5, 10, 20, 30 and 60 min. after the reaction has started, is detd. by titrating the free I by means of $Na_2S_2O_3$ soln. The reaction was carried out either in 50% AcOH or in neutral soln. (96% EtOH). The reaction temp. was 20° and 30°. The reaction proceeded faster in neutral soln. As regards the activity, the oxidizing agents range $CaOCl_2 > H_2O_2 > HNO_3 > PhSO_2NCl_2$ in neutral and $MeC_6H_4SO_2NaNCl > CaOCl_2 > K_2CrO_4 > H_2O_2 > KMnO_4 > PhSO_2NCl_2 > HNO_3$ in acid soln.
Gertrude Berend

The condensation product of toluhydroquinonecarboxylic acid and its derivatives. Gilbert Flumiani. *Rad Jugoslav. Akad. Znanosti Umjetnosti* 232, 165-71; *Chem. Zentr.* 1938, I, 1353.—The product formed by the condensation of toluhydroquinonecarboxylic acid (I) in concd. H_2SO_4 was freed from by-products by dissolving in KOH and then acidifying. It was converted into dimethylanthracene by distg. with Zn dust in a current of H. From the latter or dimethylanthraquinone the following compds. were prepd.: *1,5-dinitro-2,6-dimethylanthraquinone, 1,5-diamino-2,6-dimethylanthraquinone* (dark-red needles, m. 255°), *diazonium iodide* (orange needles, m. 272°); *2,6-dimethyl-1,5-dianthraquinonylaminoanthraquinone; 2,6-anthraquinonecarboxylic acid* (m. above 400°), *chloride* (yellow needles, m. 198°), *acid amide* (crystals from HOAc, m. above 380°); and *2,6-di-α-naphtholanthraquinone* (microscopically small needles, m. 183°). The structural formula for the condensation product from I is given as *2,6-dimethyl-1,4,5,8-tetrahydroxyanthraquinone.*
W. A. Moore

Some selenium derivatives of benzyl. G. Speroni and B. Simi. *Atti X° congr. intern. chim.* 3, 358-63(1939).—Poggi and Speroni (*C. A.* 29, 1060[6]) prepd. bis(*p*-chlorbenzyl) and bis(*p*-bromobenzyl) diselenides by agitating a mixt. of Se in aq. Na_2S with the required halogen-substituted benzyl halide. On treating $o\text{-}O_2NC_6H_4CH_2Cl$ in the same way a well-crystd., orange-yellow *compd.* (I) with the compn. $3[(o\text{-}O_2NC_6H_4CH_2Se)_2].2[(o\text{-}O_2NC_6H_4CH_2S)_2]$, ($C_{38}H_{30}N_6O_{10}Se_8S_2$)$_2$, was obtained. I was also formed by crystg. a mixt. of $(o\text{-}O_2NC_6H_4CH_2)_2Se_2$ (II) and $(o\text{-}O_2NC_6H_4CH_2)_2S$ (III) from benzene. A similar compd. was obtained from $2,5\text{-}Cl(O_2N)C_6H_3CH_2Cl$. Thermal analysis of a mixt. of II and III showed the existence of a compd. contg. 60% of II which sepd. into its components in the liquid phase. Accordingly II and III present in their mixt. an example of monotropic dimorphism.
C. R. Addinall

The acetylation of aldoximes. II. The inversion of configuration in the preparation of carbanilino aldoximes from phenyl isocyanate and *syn*-aldoximes. A. E. Ramsford and C. R. Hauser. *J. Org. Chem.* 4, 480-92(1939); cf. *C. A.* 30, 1762[3].—The reaction of α- and β-aldoximes with various acylating reagents and the action of bases on the acyl derivs. are studied. According to Brady and McHugh (*C. A.* 20, 179) PhNCO (I) is capable of converting certain α-aldoximes into carbanilino β-derivs. It is generally believed that the acyl derivs. of β-aldoximes only give nitriles with alkali while the acyl derivs. of α-aldoximes regenerate with alkali the original α-aldoximes. There are, however, some acyl α-aldoximes which with alkali give partially or even largely nitrile. In certain cases in which the isomeric β-derivs. cannot be isolated, acyl α-aldoximes which give considerable amts. of nitrile with alkali may be mistaken for β-isomers, e. g., the carbethoxy-α-aldoximes were formerly assigned the β-configuration, but when treated with cold alkali or $BuNH_2$ (cf. *C. A.* 30, 6723[6], 7556[3]) they give quantitatively the original α-aldoxime. The same is shown with the diphenylcarbamyl deriv. The reaction of I with aldoxime is carried out in a neutral soln., giving the β-, or a mixt. of α- and β-derivs. with α-aldoximes, and the β-deriv. with β-alloximes. Brady's statement that α-aldoximes reacting with I are capable of causing inversion of the configuration while naphthyl isocyanate (II) apparently is not, is confirmed by the pyridine and $BuNH_2$ test. A study of the I derivs. of α- and β-3,4-methylenedioxybenzaldoxime (III and IV), α- and β-4-methoxybenzaldoxime (V and VI), α- and β-3-nitrobenzaldoxime (VII and VIII), and the α-4-dimethylaminobenzaldoxime (IX) prepd. under various conditions show that III chiefly gives the β-acyl deriv. while IV gives only the β-acyl deriv. as shown by the formation of 3,4-methylenedioxybenzoic acid with hot alkali. This is supported by the pyridine and $BuNH_2$ test. When III reacts with I in 4-5 times the min. amt. of Et_2O, only *carbanilino-α-3,4-methylenedioxybenzaldoxime*, m. 127°, crystallizes. V and I give a ppt. which consists, when formed immediately, mostly of the β-, when it seps. out in 10-15 min., entirely of the *α-deriv.*, m. 110°, while VI gives the β-deriv. VII gives a mixt. of α- and β-derivs. from which the pure *α-compd.*, m. 148°, is obtained by recrystn. from EtOH. VIII gives the pure β-deriv. IX gives only the *β-deriv.*, m. 118°, which, when heated with EtOH, is converted into the α-form. The mechanism for the inversion of the configuration taking place in the reactions between I and α-aldoximes is discussed and from this it is predicted that no inversion should occur when the reaction is carried out in the presence of sufficient base strength to prevent the formation of an intermediate with a pos. charge on the N atom. A series of expts. is carried out in the presence of Et_3N, Pr_3N, $C_6H_4(NMe_2)CHO$ (X), $PhNMe_2$ (XI), and pyridine (XII). The results are given in a table. Only X and XII are insufficiently basic to prevent inversion. IX in the presence of a relatively large amt. of XI gives with I only the α-deriv. which is recovered unchanged from XII and m. 150-2°. This confirms the above prediction.
F. E. Brauns

Constitution of natural tannins. VI. Coloring matters derived from 2,5-dihydroxyacetophenone. Alfred Russell and Samuel F. Clark. *J. Am. Chem. Soc.* 61, 2651-8(1939); cf. *C. A.* 31, 3897[7].—Syntheses are described of polyhydroxychalcones, flavanones and anthocyanidins from $2,5\text{-}(HO)_2C_6H_3Ac$ (I) and various HO aldehydes; I was selected because of the occasional occurrence of quinol as a decompn. product of natural materials, suggesting a benzopyran compd. hydroxylated in the 6-position. *m-Benzoyloxybenzaldehyde* (II), m. 37-8°, *resorcylaldehyde dibenzoate* (III), m. 98°; *orcylaldehyde dibenzoate* (IV), m. 134-5°. Benzoyloxychalcones were prepd. by passing dry HCl into a soln. of I and the aldehyde benzoate in AcOEt for 2-5 days at 0°, the soln evapd. to a thick red syrup and triturated with EtOH. Hydroxychalcones were prepd. by adding aq. KOH to the boiling EtOH soln. of the Bz derivs. over a period of 40-60 min., distg. off the original vol. of EtOH used, cooling and acidifying with dil. H_2SO_4; the BzOH was sepd. by cold $NaHCO_3$ or by ext. with hot C_6H_6; flavanones were removed by fractional crystn. from dil. EtOH. II dibenzoate (V) and *p*-$BzOC_6H_4CHO$ give 78% of *4,2',5'-tribenzoyloxychalcone*, pale yellow, m. 134-6°; *tri-HO deriv.*, orange-yellow, m. 222-4°, 50% yield. V and II give 67% of *3,2',5'-tribenzoyloxychalcone*, light yellow, m. 174-5°; *tri-HO deriv.*, orange, m. 204-6°, 20% yield; there also resulted 12% of *6,3',-dihydroxyflavanone*, pale yellow, m. 234-6°. V and vanillin benzoate give 88% of *4,2',5'-tribenzoyloxy-3-methoxychalcone*, pale yellow, m. 145-7°; *tri-HO deriv.*, dark orange, m. 172-3°, 46%. V and protocatechualdehyde dibenzoate give 78% of

3,4,2',5'-tetrabenzoylchalcone (VI), pale yellow, m. 182–4°; *tetra-HO deriv.*, dark orange, m. 225–7°, 66%; *6,3',4'-trihydroxyflavanone* (VII), pale yellow, m. 218–20° (decompn.). V and *o*-$BzOC_6H_4CHO$ give 82% of *2,2',5'-tribenzoyloxychalcone*, bright yellow, m. 137–9°; on debenzoylating 27.5 g., there was obtained less than 1 g. of *2',5'-dihydroxy-2-phenylbenzopyrylium chloride*, purified by extn. with Et_2O, red, m. 175°; the acid soln. is red, the Na_2CO_3 soln. is blue; *6,2'-dihydroxyflavanone*, pale yellow, m. 178–80° (decompn.); the chalcone is formed only in traces. V and III give 80% of *2,4,2',5'-tetrabenzoyloxychalcone*, yellow, m. 137–9°; debenzoylation gives 39% of *7,2',5'-trihydroxy-2-phenylbenzopyrylium chloride*, dark red, m. 190° (decompn.). V and IV give 86% of *2,4,2',5'-tetrabenzoyloxy-6-methylchalcone*, pale yellow, m. 125–7°; *7,2',5'-trihydroxy-5-methyl-2-phenylbenzopyrylium chloride*, dark-red, iridescent plates, m. 285–7° (decompn.). V and phloroglucinaldehyde tribenzoate give *2,4,6,2',5'-pentabenzoyloxychalcone*, a yellow oil, which yields *5,7,2',5'-tetrahydroxy-2-phenylbenzopyrylium chloride*, brownish red, m. above 300°. Reduction of VII or of a mixt. of VII and VI with Zn and HCl in EtOH gives *bis(5,3',4'-trihydroxy)flavopinacol*, light-red friable solid; this is qualitatively indistinguishable from such natural phlobatannins as hemlock and mimosa tannins. C. J. West

Fluorinated aromatic mercurials. Melvin F. W. Dunker and Edgar B. Starkey. *J. Am. Chem. Soc.* **61**, 3005–7(1939); cf. *C. A.* **31**, 3809.—PhF, $Hg(OAc)_2$ and AcOH, refluxed 12 hrs., cooled and treated with dil. HCl, the ppt. extd. with AcOH and the ext. crystd. from MeOH, give about 11% of *o-fluorophenylmercuric chloride* (I), m. 159–60°; no other product could be isolated. I is also obtained in 24% yield from *o*-$FC_6H_4NH_2$ through the diazonium fluoborate; the *p*- and *m*-isomers result in 24 and 28% yields, resp. *p*-FC_6H_4OH (13 g.) and $Hg(OAc)_2$ in Ac_2O contg. a little AcOH give 34 g. of *4-fluoro-2-acetoxymercuriphenol*, m. 193–4° (decompn.). *p*-$FC_6H_4CO_2H$ gives a poor yield of *4-fluoro-3-chloromercuribenzoic acid* (II), m. 239° (decompn.); it could not be crystd. Catalytic reduction of 4,3-$F(O_2N)C_6H_3CO_2H$ gives 98% of *3-amino-4-fluorobenzoic acid*, tan, m. 182–3° (decompn.); *HCl salt*, m. 240–3°; *Ac deriv.*, m. 245–6° (decompn.); on slow heating the Ac deriv. decomps. at 200°; through the diazo reaction there results 77% of *2-fluoro-5-carbethoxybenzenediazonium fluoborate*, cream, decomps. 185°; this gives a poor yield of II; above its m. p. II gives I. C. J. West

Ethers of *p*-hydroxybenzoic acid as derivatives for the identification of alkyl halides. W. M. Lauer, P. A. Sanders, R. M. Leekley and H. E. Ungnade. *J. Am. Chem. Soc.* **61**, 3050(1939).—*Ethers* of *p*-$HOC_6H_4CO_2H$ were prepd. from the Et ester in EtONa and the alkyl halides by refluxing 0.5–1 hr., distg. off part of the alc., adding H_2O to dissolve the ppt. NaCl, extg. with Et_2O and hydrolyzing the ester with KOH in MeOH. M. ps. are given for those ethers reported in the literature; the following appear to be new but no analyses are given: *sec*-Bu m. 121–3°, α-methylallyl m. 155–6°, γ-isomer m. 176.5–8°, α-ethylallyl m. 108–9°, γ-isomer m. 156.5–8°, α,γ-dimethylallyl m. 131–2°, α-propylallyl m. 74.5–5°, γ-isomer m. 139.5–40°. C. J. West

The crystallization of salicylic acid from mixtures of salicylic acid and α-naphthol. Angelo Castiglioni. *Gazz. chim. ital.* **69**, 444–7(1939).—Since the system α-naphthol (I)-salicylic acid (II) behaves in an ideal way with respect to sepn. of II from both dil. and concd. solns. (cf. *C. A.* **31**, 8528[2]), it was of interest to ascertain whether the system follows the crystn. law of Volmer (*C. A.* **16**, 4119) in its logarithmic form: $\log v = \log k + n \log c$. Rather than det. directly the no. of crystal germs as a function of time, the times of crystn., i. e., the reciprocal of the times for the appearance of the 1st germs, were detd. by the method of Othmer (*C. A.* **9**, 1866). Mixts. of I and II in various proportions were heated to 175°, then maintained at various temps. (23°, 33°, 41°, 51°, 66°, 71° and 80°) and the times for the appearance of the 1st germs detd. As recorded graphically, with $\log v$ as a function of $\log c$, the curves for the various temps. show that the law of Volmer does not hold true for all temps. or all concns. of II. Thus at 80° the curve has no straight section, and even at the low temps. the curves are straight only at relatively high concns., e. g., at 71° the straight section is limited to 80–100% concn. of II and at 23° to 40–100% concn. of II. This adherence to the law of Volmer only between definite limits of temp. and concn. was found to be true also of palmitic acid-stearic acid mixts. (cf. Rawitzer, *C. A.* **23**, 1322). C. C. Davis

Acetylsalicylic acid and its methods of preparation. Ignazio Mininni Jannuzzi. *Farm. ital.* **7**, 729–33(1939).—Descriptive. L. E. Gilson

Metabolic products of Aspergillus ochraceus. III. Synthesis of isoöchracin. Teiiti Tamura. *J. Agr. Chem. Soc. Japan* **15**, 685–9; *Bull. Agr. Chem. Soc. Japan* **15**, 112–13(1939)(in English).—7-Nitro-3-ethylidenephthalide, m. 178°, was prepd. from 3-nitrophthalic anhydride and $(EtCO)_2O$. When it was treated with NaOH and Na-Hg, 7-amino-3-ethylphthalide was obtained. Its HCl salt, m. 168–70°, was treated with dil. H_2SO_4 and 10% $NaNO_2$. 7-Hydroxy-3-ethylphthalide, m. 81°, was isolated. There was no depression of the m. p. when it was mixed with isoöchracin, m. 79°. Colorless prisms (I), m. 125°, were prepd. from 3-methoxyphthalic anhydride and $(EtCO)_2CO$. Colorless feather-like crystals, m. 58° (II), were isolated by treating I in alk. soln. with Na-Hg. When isoöchracin was treated with CH_2N_2, an oily substance giving no $FeCl_3$ reaction was obtained. It could not be crystd. Hence I and II may be, resp., 4-methoxy-3-ethylidenephthalide and 4-methoxy-3-ethylphthalide. Y. Kihara

Benzoylformic acid from styrene. Charles D. Hurd, R. W. McNamee and Frank O. Green. *J. Am. Chem. Soc.* **61**, 2979–80(1939).—$PhCH{:}CH_2$ (I) (18 g.) and 9 g. NaOH in 100 cc. H_2O, treated with 75 g. $KMnO_4$ in 1500 cc. H_2O in 6 portions at 70°, give 55% of $PhCOCO_2H$ (II). I from drip oil (about 50% purity) gives 39% of II (based on the content of I). C. J. West

The constitution of barbatolic acid. Eero E. Suominen. *Suomen Kemistilehti* **12B**, 26–8(1939)(in German).—The extn. of 500 g. of the lichen *Alectoria implexa* f. *fuscidula* for 5 days with Et_2O in a Soxhlet app., concn. of the ext. to 200 ml. and filtration yields 32 g. of a brown solid. This is extd. by boiling twice with C_6H_6 and once with Me_2CO, after which the residue is crystd. from 200 parts of dioxane, yielding 15.5 g. (3.1%) of *barbatolic acid*, $C_{18}H_{16}O_{10}$ (I), m. 205–6°, white crystals from dioxane, difficultly sol. in most org. solvents, easily sol. in alkalies and $NaHCO_3$ to give intensely yellow solns., and giving a red-brown color in EtOH with $FeCl_3$. The dioxime of I (see Schopf, Hetek and Duntze, *C. A.* **26**, 1275), m. 207–8°, gives a violet color in EtOH with $FeCl_3$. Splitting of I with alkali gives atranol (II) (cf. Pfau, *C. A.* **21**, 1289), barbatol and barbatorin. Methylation of 2.5 g. of I in 500 ml. of dioxane and 1250 ml. of Et_2O in the cold with CH_2N_2, concn. to small vol. and treatment with 2 parts of H_2O yielded 2 g. of *Me barbatolate*, $C_{19}H_{16}O_{10}$ (III), m. 193° (from AcOH). It dissolves in alkalies to give a yellow color and gives a brown-red color in EtOH with $FeCl_3$. On heating 0.25 g. of III with AcOH in a sealed tube at 140–5° for 15 hrs., and evapn. to dryness *in vacuo*, 220 mg. of cryst. product was obtained. Sublimation of the crystals at 0.02 mm. yielded fractions at 90–130° and 130–80°. The 1st fraction after crystn. from H_2O gave 85 mg. of II, m. 118–19° (greenish yellow crystals), which gave no m.-p. depression with authentic II obtained from atranorin. The 2nd fraction (100 mg.), crystd. from H_2O as a light-brown powder, sol. in hot EtOH, Me_2CO and H_2O, difficultly sol. in Et_2O, m. 243–4° (decompn.), consisted of *barbatolcarboxylic acid*, 3,6,2,4-$OHC(HOCH_2)(HO)_2C_6HCO_2H$ (IV). IV gives a wine-red color with $FeCl_3$ in EtOH. The reduction of 0.125 g. of III in AcOH with HI and Zn at 70° and extn. with Et_2O of the combined products of 2 reductions yielded 0.2 g. of an oil which gave the *reduction product* $C_{19}H_{20}O_8$ (V), m. 189–90° (decompn.), by soln. in 9:1 MeOH-

dioxane and pptn. with 25 parts of H_2O. V is easily sol. in EtOH and Et_2O, and sol. in hot C_6H_6. V in alc. gives a violet color with $FeCl_3$, while its alk. soln. is colorless. The reduction mother liquors yielded small amts. of β-orcinol and the Me β-orcinolcarboxylate. V (0.5 g.) was treated in abs. Et_2O with small amts. of CH_2N_2 twice a week until a portion in EtOH no longer gave a color with $FeCl_3$ (2 months). The soln. was evapd. to dryness, yielding 0.6 g. of oil which was taken up in petr. ether, filtered from 0.06 g. of insol. residue, evapd. again to dryness, taken up in Et_2O and cooled in Me_2CO-CO_2 snow. The soln. was filtered from a white flocculent ppt., the filtrate evapd. to dryness and the residue taken up in petr. ether and again cooled. Repeated soln. in petr. ether and cooling gave 340 mg. of the *methylated product* $C_{18}H_{14}O_4(OMe)_4$ (VI), and oil at room temp. A high MeO value indicated that a small amt. of $C_{18}H_{13}O_3(OMe)_5$ might be present. Concd. EtOH solns. of VI gave a violet color with $FeCl_3$. Splitting of VI was accomplished by boiling 0.1 g. with 10 ml. of 0.2 *N* alc. KOH for 3 hrs. under reflux. The alk. soln. was acidified, extd. with Et_2O and the Et_2O soln. extd. with $KHCO_3$. Acidification of the $KHCO_3$ soln. with HCl and extn. with Et_2O yielded 40 mg. of a mixt. of rhizoninic acid (2,5-dimethyl-4-methoxy-5-hydroxybenzoic acid) (VII) and the Me ether of VII. The Et_2O soln. after extn. with $KHCO_3$ was extd. with 8% NaOH. Concn. of the Et_2O soln. yielded 42 mg. of the *2-hydroxymethyl-4,6-dimethoxy-5-methylbenzoic lactone* (VIII), m. 173.5°, white crystals from dil. EtOH. Acidification of the NaOH soln. and extn. with Et_2O yielded 10 mg. of oily yellow crystals consisting mainly of VIII. VIII gave no color with $FeCl_3$. The data indicate that I is 6,3,2,4-$ROCH_2(OHC)(HO)_2C_6HCO_2H$, not 6,3,2,4-$HOCH_2(OHC)(OH)(RO)C_6HCO_2H$ (R = 6,3,2,4-$Me(OHC)(OH)_2C_6HCO$), as suggested by S., H. and D.

S. A. Karjala

Constitution of halogenated resaceto- and resopropiophenones. Duhkhaharan Chakravarti and Niranjan Chakravarty. *J. Indian Chem. Soc.* **16**, 144-50(1939); cf. *C. A.* **32**, 1255¹.—4-Chlororesorcinol (25 g.) was added to a soln. of freshly fused $ZnCl_2$ (25 g.) in 25 cc. AcOH and the mixt. heated to 145° for 3 min. Treatment with 25 cc. concd. HCl and 25 cc. H_2O gave 10 g. of *5-chloro-resacetophenone* (I), m. 171°; *semicarbazone*, m. 315°. I (5 g.), Zn-Hg (40 g.) and HCl (1 2, 120 cc.) were refluxed for 4 hrs. Et_2O extn. of the filtered soln. gave 3 g. of *4-chloro-6-ethylresorcinol* (II), m. 84°. II (1 g.) and $AcCH_2CO_2Et$ (1 g.) were condensed in the presence of 2 cc. H_2SO_4 in the cold. After 12 hrs. the soln. was poured into crushed ice to give *6(or 8)-chloro-5-hydroxy-4-methyl-8(or 6)-ethylcoumarin* (III), m. 175°; *acetate*, m. 100°. III was also prepd. with P_2O_5 instead of H_2SO_4. *6(or 8)-Chloro-5-hydroxy-3,4-dimethyl-8(or 6)-ethylcoumarin*, m. 183°, was obtained by condensing II with *Et methylacetoacetate* in presence of H_2SO_4. II may be prepd. by adding SO_2Cl_2 slowly to *4-ethylresorcinol* in ice-cooled ether. *5-Chlororesopropiophenone* (IV), m. 90°, was prepd. like I. Clemmensen's reduction of IV gave *4-chloro-6-propylresorcinol*, m. 63°; the mother liquor gave some *4-propylresorcinol* (V), m. 77°. V was also obtained by Clemmensen's reduction of resopropiophenone. 6-Propylresorcinol was condensed with Et acetoacetate using H_2SO_4, to give *6-propyl-4-methyl-7-hydroxycoumarin*, m. 174°. Similar treatment of IV gave *6(or 8)-chloro-5-hydroxy-4-methyl-8(or 6)-propylcoumarin*, m. 185°. Clemmensen reduction of *5-bromoresacetophenone*, m. 167° (*semicarbazone*, m. 255°), gave *4-ethylresorcinol* (VI), m. 97°. VI with Et acetoacetate gave *7-hydroxy-6-ethyl-4-methylcoumarin*, m. 210°. Dry HCl gas was passed into 10 g. chloroörcinol in dry Et_2O and $PhCH_2CN$ (10 g.) contg. fused $ZnCl_2$ (4 g.) and the mixt. was set aside for 2 days. The Et_2O ext. gave 3 g. of a *ketone* (VII), $C_{15}H_{14}O_3$, m. 140°. Clemmensen reduction of VII gave a product m. 127°. When orcinol is used in the above reaction a *ketone*, m. 160°, is obtained, which on reduction gives a *compd.* m. 72°. Clemmensen reduction of coumarin gives a colorless compd., m. 235°.

W. J. Peterson

Limited applicability of Kostanecki's reaction. The influence of halogen atoms on the reaction. Duhkhaharan Chakravarti and Brojeswar Majumdar. *J. Indian Chem. Soc.* **16**, 151-9(1939).—*4-Chloro-2-methylphenyl acetate* (20 g.) was mixed with powd. $AlCl_3$ (20 g.) and the mixt. heated at 120° for 20–30 min. After decompn. with dil. HCl and steam distn., 15 g. of *5-chloro-3-methyl-2-hydroxyacetophenone*, m. 70°, was obtained; *semicarbazone*, m. 283°. The following were similarly prepd.: *5-chloro-3-methyl-2-hydroxypropiophenone*, m. 61° (*semicarbazone*, m. 205°); *3-chloro-4-hydroxypropiophenone*, m. 80° (*acetate*, b. 155°); *3-bromo-4-hydroxypropiophenone*, m. 130°; *5-bromo-2-hydroxypropiophenone*, m. 78°. The general method for the acetylation, propionylation and butyrylation of the aceto- and propiophenones was as follows: A mixt. of the *o-HO ketone* (4 g.), fused Na salt of the *fatty acid* (6–10 g.) and the *anhydride* of the acid (30–40 g.) was heated at 170–80° for 12 hrs. The mixt. was then poured into H_2O and heated at 100° for 0.5 hr. The solid was then crystd. from an appropriate solvent. The following compds. were prepd.: *6-chloro-2,8-dimethyl-3-acetylchromone*, m. 139°; *8-chloro-2,6-dimethyl-3-acetylchromone*, m. 131°; *6-chloro-2,3,8-trimethylchromone*, m. 124° (*styryl deriv.*, m. 166–7°); *8-chloro-2,3,6-trimethylchromone*, m. 154-6° (*styryl deriv.*, m. 183°); *6-chloro-2,3-dimethylchromone*, m. 86–7° (*styryl deriv.*, m. 144–5°); *6-bromo-2,3-dimethylchromone*, m. 113°; *6-chloro-3,4,8-trimethylcoumarin*, m. 94°; *8-chloro-3,4,6-trimethylcoumarin*, m. 157°; *6-chloro-3,8-dimethyl-2-ethylchromone* (I), m. 85°; *8-chloro-3,6-dimethyl-2-ethylchromone*, m. 74–5°; *6-chloro-2-ethyl-3-methylchromone*, m. 65–6°; *6-bromo-2-ethyl-3-methylchromone*, m. 87°; *6-chloro-3,8-dimethyl-2-propylchromone*, m. 95°; *8-chloro-2-propyl-3,6-dimethylchromone*, m. 68–71°; *6-chloro-2-propyl-3-methylchromone*, m. 85°; *6-bromo-2-propyl-3-methylchromone*, m. 83–4°. I was let stand in alc. NaOEt for 12 hrs. After acidification with HCl and extn. with Et_2O the Et_2O ext. was washed repeatedly with cold alkali (5%) and then with H_2O. Acidification of the alk. wash with HCl gave *5-chloro-2-hydroxy-3-methylpropiophenone*, m. 61°. A mixt. of *5-chloro-2-hydroxyacetophenone* (0.5 g.), and $EtCO_2Et$ (22 g.) was added to molecular Na (3.5 g.) with cooling. After heating for 1 hr. at 100° and decompn. with ice, the dried Na salt was methylated in Me_2CO with MeI to give a sticky mass, which, after drying and heating with AcOH and HBr (1 cc.) for 1 hr. on the water bath, gave *6-chloro-3-methyl-2-ethylchromone*, m. 123°.

W. J. Peterson

Monoalkyl phthalates from normal aliphatic alcohols. James F. Goggans, Jr., and J. E. Copenhaver. *J. Am. Chem. Soc.* **61**, 2909-10(1939).—The following esters show sufficient variation in the m. ps. through the dodecyl compd. so that they could be used as checks on the identification of the individual ales. Up to the decyl ester the m. ps. give a curious pattern; above this ester the curve exhibits regular alternations. *Monoalkyl phthalates* were prepd. by refluxing the anhydride and alc. for varying periods from 30 min. to 2 hrs., depending upon the mol. wt. of the alc. The m. ps. given are cor.: Me 82.4–2.7°, *Pr* 54.1–4.4°, *Bu* 63.1–3.5°, *Am* 75.4–5.6°, *hexyl* 24.6–5.4°, *heptyl* 16.5–17.5°, *octyl* 21.5–2.2°, *nonyl* 42.4–2.6°, *decyl* 37.8–8.0°, *undecyl* 43.8–4.1°, *dodecyl* 50.2–50.4°, *tridecyl* 52.4–2.7°, *tetradecyl* 59.8–60°, *pentadecyl* 60.3–60.5°, hexadecyl 66.7–6.8°, *heptadecyl* 66.6–6.8°, *octadecyl* 72.4–2.6°, *nonadecyl* 70.8–1°, *eicosyl* 77.1–7.3°.

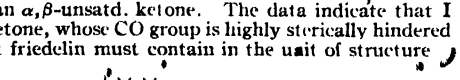
C. J. West

Reaction of the Grignard reagent with homophthalic anhydride. Charles C. Price, Frederick M. Lewis and Morris Meister. *J. Am. Chem. Soc.* **61**, 2760-2(1939).—*o*-$MeC_6H_4CO_2H$ is transformed into the chloride by $SOCl_2$ (refluxing 2 hrs.) which with Br at 185–95° (added during 1–2 hrs.) followed by cooling and addn. of abs. EtOH yields *o*-$BrCH_2C_6H_4CO_2Et$; refluxing with NaCN for 5 hrs. gives 71–6% of *α-carbethoxyphenylacetonitrile*, b_{16} 170–70.5°, d_{25}^{25} 1.1246, n_D^{25} 1.5172. Hydrolysis with 50% H_2SO_4 (12 hrs. at 100°) gives over 90% of *o*-$HO_2CC_6H_4CH_2CO_2H$, which with AcCl gives 95% of homophthalic anhydride (I). Another method for the prepn. of I is to

start with phthalide which with KCN at 180–90° gives 82% of *o*-$NCCH_2C_6H_4CO_2H$, the remainder of the synthesis being as above. Reaction of I with MeMgI does not lead to *o*-$AcC_6H_4CH_2CO_2H$ (II) but 50% of the starting material is recovered and the other half is converted to dimethylhomophthalide. In a few cases the possible presence of II was indicated. The course of the reaction is outlined. C. J. West

Oxidation of terpenes. R. Dupont. *Ind. chim. belge* 10, 307–19(1939).—Review with numerous references. John F. Lontz

Addition of oxygen to double bonds. Syoko Tanaka. *Mem. Coll. Sci., Kyoto Imp. Univ.* A22, 97–127(1939). 3-*p*-Menthene (I), made by dehydrating menthol over Al_2O_3 at 300°, was oxidized by the calcd. amt. of BzO_2H (II) or AcO_2H (III) in $CHCl_3$ or Et_2O at 0° to *3,4-menthene oxide* (IV), b_{14} 74–5°, d_4^{25} 0.8946, n_D^{25} 1.4460, $[\alpha]_D$ 54.21°, for which the mol. refraction, heat of combustion, and parachor correspond to the structure assigned I was not oxidized by Caro's acid, menthene ozonide, or BzO_2Na, which liberates O under the exptl. conditions, indicating that "active O" does not take part in the formation of IV. IV shaken with 10% H_2SO_4 at 0° gave *menthene glycol (3,4-dihydroxymenthene)*, m. 75 6°, converted to *i*-menthone (V) by 10% H_2SO_4 on a H_2O bath. IV passed over Al_2O_3 at 250° gave V and a *terpene*, b. 171–3°, d_4^{25} 0.8294, n_D^{25} 1.4647. To 30 g. of I in 500 cc. of NaOCl soln. contg. 3.6 g. of available O, 200 cc. of 2% $ZnSO_4$ soln. was slowly added. Extn. with Et_2O gave a very unstable *menthene chlorohydrin* (VI). I in moist Et_2O with HgO and I gave a similar *menthene iodohydrin* (VII). VI and VII were converted to IV by powd. KOH. Attempts to form acyl derivs. by warming VII with AcOAg and BzOAg likewise gave IV, indicating that the formation of IV from I may consist of addn. of II or III to form the unstable esters, which then lose AcOH or BzOH to form IV. IV heated with a trace of AcOH at 100–20° gave a viscous, non-distillable *polymer*. 2,6-Dimethyl-2-octene, I, C_9H_{18}-CHO, PhCH CH_2, and BzH were oxidized by III at decreasing rates in the order named. Arnold M. Collins



Bicyclic structures prohibiting the Walden inversion. Replacement reactions in 1-substituted 1-apocamphanes. Paul D. Bartlett and Lawrence H. Knox. *J. Am. Chem. Soc.* **61**, 3184–92(1939).—*Apocamphane-1-carboxamide* (I) has been converted by the Hofmann reaction into *1-aminoapocamphane* (II). Although the NH_2 group is so situated that it cannot possibly be replaced in any reaction involving a Walden inversion, this compd. readily reacts with HNO_2 to yield *apocamphan-1-ol* (III) and with NOCl to yield *1-chloroapocamphane* (IV). III and IV cannot be interconverted. The alc. forms loose mol. compds. with HCl and HBr, whereas IV withstands 48 hrs. of boiling with $AgNO_3$ in dil. EtOH soln. without producing any opalescence. It is concluded from the reactions of the amide and amine that the Walden inversion, in which the neg. substituent replaces another on the opposite side of the same C atom, is not a universal necessity for the occurrence of a "neg. substitution" reaction. The inertness of the bridge-head HO group and Cl atom may be interpreted as indicating either that a Walden inversion is absolutely necessary in the replacement of these groups or that in a carbonium ion the central C atom and the 3 atoms forming bonds with it must be coplanar. Certain drawbacks to the former of these interpretations are pointed out. Oxidation of 100 g. of *dl*-camphor-10-sulfonyl chloride by adding it in 3 portions with stirring to 1000 g. of a 10% soln. of Na_2CO_3 heated on the steam bath, together with the 3 corresponding portions of a hot soln. of 100 g. of $KMnO_4$ in 600 cc. H_2O and heating for 1 hr., gives 38–43% of *dl-ketopinic acid* (V), m. 233–4°. Reduction of V by the Wolff-Kishner or the Clemmensen method gives 62 and 50%, resp., of *apocamphane-1-carboxylic acid*, m. 217–18°; the Clemmensen method is better for larger quantities. Refluxing with $SOCl_2$ and reaction with NH_3 give 92% of I, m. 185°. I (25 g.) and 7 g. Na in 385 cc. MeOH, cooled and treated with 24 g. Br (dropwise with stirring), finally refluxed 15 min., give 60% of *Me 1-apocamphylcarbamate*, m. 93–4°; refluxing with KOH in MeOH gives 82.7% of II, m. 175° (HCl salt, discolors at 235–40° and does not m. 320°); *Ac deriv.*, m. 132°; *Bz deriv.*, m. 112°. II and HNO_2 give 66.6% of III, m. 161–2°; *p-toluenesulfonate*, m. 93°. III and HBr give a *solid*, $C_{18}H_{33}O_2Br$, m. 83–4°, which fumes strongly in the air. With PCl_5 III gives a *compd.*, $C_{18}H_{33}O_2Cl$, m. 157–68°; it is not IV. II and NOCl give IV, m. 154–6°, in 45% yield. After refluxing IV 21 hrs. with 30% KOH in 80% EtOH 70% of IV was recovered unchanged and no III could be obtained by a H_2SO_4 extn. A Grignard reagent could not be prepd. with IV. Bornyl chloride and $AgNO_3$ in EtOH, refluxed 60 min., show 84% reaction; this corresponds to a bimol. velocity const. (in hrs.) of 11.25, thus certainly at least 10^{10} greater than the corresponding const. for IV. From these expts. it appears that III and II are unique among known alcs. and satd. chlorides in their resistance to replacement of their functional groups and that this uniqueness can be assocd. only with the location of these groups on the bridge-head of a bicyclic ring system. *tert*-BuCEt_2OH and HCl at 0° give *2,2-dimethyl-3-ethyl-3-chloropentane*, b_6 53–4°; hydrolysis at 25° in 80% EtOH gives a unimol. velocity const of 0.4206 (in hrs.). C. J. West

4-Methylbornylene and its hydration. A. I. Shavrygin. *J. Gen. Chem.* (U. S. S. R.) 9, 516–21(1939).—Dehydration of 4-methylborneol and 4-methylisoborneol (I) by the xanthate method gives only 4-methylbornylene. When this is heated with AcOH in the presence of H_2SO_4 or $ZnCl_2$, only the acetate of I is obtained. This is easily sapond. to give I. Since no new alc. is obtained, doubt is cast on the work of Achmatowicz (*C. A.* **22**, 4517) and Krestinskii and Eshchenko (*C. A.* **31**, 4304[3]). H. M. L.

Intramolecular transformations during the dehydration of ditertiary bicyclic glycols of the camphane series. I. L. Ya. Bryusova. *J. Gen. Chem.* (U. S. S. R.) 9, 905–11 (1939).—4-Methylcamphorquinone (15 g.) in Et_2O was added in small portions with cooling to a soln. of MeMgI, prepd. from 6 g. Mg, 40 g. MeI and 30 ml. abs. Et_2O. The reaction product, worked up in the usual manner, gave 12 g. 2,3,4-trimethyl-2,3-dihydroxycamphane (I), m. 132 5°. I (12 g.) was treated on an oil bath with 35 g. $KHSO_4$ and 5 g. Na_2SO_4 at 150–5° for 5 hrs. The reaction mixt., after treatment with steam, yielded an unsatd. ketone (6-isopropylidene-2,2,3,3-tetramethylcyclohexanone or 3-isopropylidene-2,2,6,6-tetramethylcyclohexanone), b_{20} 126–7°, d_4^{20} 0.9602, n_D^{19} 1.4890, which gave a semicarbazone, m. 193 4°. Camphorquinone (30 g.) on treatment with MeMgI gave 28 g. 2,3-dimethyl-2,3-dihydroxycamphane (II), m. 132°. This amt. of II was heated with 80 g. $KHSO_4$ and 12 g. Na_2SO_4 at 150–5° for 5 hrs. The reaction product, after treatment with steam, vacuum distn., and reaction with semicarbazide, gave the semicarbazone (III), m. 180–1°, of an unsatd. ketone (6-isopropylidene-2,2,3-trimethylcyclohexanone or 3-isopropylidene-2,2,6-trimethylcyclohexanone) (IV). IV, obtained from III on treatment with 50% H_2SO_4 and steam distn., b_{10} 104.8–5°, b_{26} 128.2 9°, d_4^{20} 0.9390, n_D^{19} 1.4840. To 1 g. IV in 4 ml. 96% alc. were added 4 g. $NH_2OH.HCl$ in 4 ml. H_2O and 4 g. KOH in 4 ml. H_2O and the mixt. was warmed for 15 hrs. on the water bath, whereby the oxime of IV, m. 108–12°, was formed. Reduction of IV by means of Na and abs. alc. yielded the corresponding alc., b_{10} 122–3°, b_{20} 136 7°, d_4^{20} 0.9485, n_D^{19} 1.4961. Catalytic hydrogenation of IV, using Raney Ni as a catalyst, gave the corresponding satd. ketone, b_{12} 110–15°, d_4^{20} 0.942, n_D^{19} 1.4851. IV was not changed when treated with cold concd. H_2SO_4 for 2–3 min. Gertrude Berend

Cerin and friedelin. V. Study of friedonic acid. Nathan L. Drake and John K. Wolfe. *J. Am. Chem. Soc.* **61**, 3074–8(1939); cf. *C. A.* **30**, 7572[2].—Details are given of the prepn. of friedonic acid (I) (cf. *C. A.* **31**, 7571[9]) in 48% yield. In some expts. an *isomer* (II), m. 126–7°, is obtained; this also results in small yield by treating I with EtONa in EtOH for 48 hrs. I and Me_2SO_4 with MeONa in MeOH or CH_2N_2 or the Na salt with MeI give the *Me ester* (III), m. 157–8°; this also results from II, Me_2SO_4 and MeONa. Heating I in an atm. of N for 2.5 hrs. at 250° gives *norfriedelene* (IV), $C_{29}H_{48}$, m. 228.5–

30°; 1 mole each of CO_2 and H_2O are lost in the reaction; a yellow color with $C(NO_2)_4$ indicates unsatn.; catalytic reduction of IV gives *norfriedelane*, m. 220-1°, needles having a slight oblique extinction (about 3.2°). Oxidation of III with $KMnO_4$ in AcOH gives *norfriedonic acid* (V), $C_{29}H_{48}O_3$, m. 215-17°; *Me ester* (VI), m. 166-7°; *oxime*, m. 270.5-3° (*Me ester*, m. 193-5°); III and 2,4-$(O_2N)_2C_6H_4NHNH_2$ give the *2,4-dinitrophenylhydrazone* of VI, bright yellow, m. 233-4°. I and $SOCl_2$, refluxed for 30 min., give an amorphous chloride, which is catalytically reduced to *norfriedelanylformaldehyde*, (VII), $C_{30}H_{50}O$, m. 222-5° (prisms with a slight oblique extinction, ca. 19.4°); *oxime*, m. 255-9°; *2,4-dinitrophenylhydrazone*, bright yellow, m. 312-14°. VII and CrO_3 in AcOH give *norfriedelanylformic acid*, $C_{30}H_{50}O_2$, m. 307-8°; *Me ester*, m. 230-1.5°. I shows an absorption max. at 2900 A. (log ε 1.55); the absorption curve in cyclohexane (1%) is given; this confirms the earlier belief that I is not an α,β-unsatd. ketone. The data indicate that I is an ε-ketone, whose CO group is highly sterically hindered and that friedelin must contain in the unit of structure

C. J. West

Bromination of 4-phenylphenyl acetate. Stewart E. Hazlet and Harry A. Kornberg. *J. Am. Chem. Soc.* **61**, 3037-9(1939); cf. *C. A.* **33**, 6282². 4-PhC₆H₄OAc (I) in AcOH at 100°, treated with a trace of Fe powder and 1.5 moles of Br over 30 min. and heated an addnl. 10 hrs., gives 57% of the *2-Br deriv.* (II), m. 74-5°; II was also prepd. in 90% yield from 2,4-BrPhC₆H₃OH and Ac_2O-AcONa on heating 5 hrs. at 100°. I and 2 moles Br at 110° for 8 hrs. give 16% of the *2,6-di-Br deriv.* (III), m. 81-3°; III was also prepd. from 2,6,4-$Br_2PhC_6H_3OH$ with Ac_2O-AcONa. 4-$O_2NC_6H_4Ph$ (IV) was converted through the 4'-Br deriv. to 4-$BrC_6H_4C_6H_4NH_2$-4 and then to 4-$BrC_6H_4C_6H_4OH$-4 (V); Ac_2O-AcONa gives a poor yield (based on the IV used) of *4-(4-bromophenyl)phenyl acetate*, m. 128-9°; V prepd. by the hydrolysis of 4-$BrC_6H_4C_6H_4OSO_2Ph$-4 (VI) gives a crude yield of 92% of the acetate (based on the VI used). These results are in keeping with a previous suggestion that steric effects may det. the positions taken by substituents entering an ester mole.

C. J. West

Odor of alkoxybiphenyls. C. M. Brewster and Ivan J. Putman, Jr. *J. Am. Chem. Soc.* **61**, 3083-5(1939).—*o*-HOC_6H_4Ph (I) (15 g.) and 3.8 g. NaOH in 85 cc. Me_2CO, refluxed for 1 hr. and treated with 15 g. PrBr (refluxed 6 hrs.) give 17 g. of *2-biphenylyl Pr ether*, b. 303°; it has a faint aromatic odor; the Me ether, b. 288°, has a faint, slightly pungent fruity aromatic odor; the Et ether has a somewhat sweeter and more flowerlike odor than the Me ether. The *iso-Pr ether*, b. 315-17° (10 g. from 10 g. I), has a faint aromatic odor; the *allyl ether*, b. 312° (13 g. from 12 g. I), has the same odor as the Pr ether; *benzyl ether*, b. 324° (4 g. from 12 g. I), pleasant nut-like odor at 100°. *4-Biphenylyl Et ether*, m. 76°, quant. yield; *Pr ether*, m. 76-7° (9 g. from 10 g. phenol); *iso-Pr ether*, m. 73° (4 g. from 10 g. phenol); *allyl ether*, m. 86° (14 g. from 12 g. phenol); *Bu ether*, m. 74-5° (13 g. from 10 g. phenol); *benzyl ether*, m. 136° (18 g. from 12 g. phenol). The *p*-ethers are odorless. C. J. West

Stereochemistry of biphenyls. XLVIII. Comparison of the racemization rates of three isomeric 2,2',6-nitro-, carboxy-, methyl-biphenyls. Roger Adams and J. B. Hale. *J. Am. Chem. Soc.* **61**, 2825-8(1939); cf. *C. A.* **33**, 7767⁶.—2,3-$Br(O_2N)C_6H_3CO_2Me$ and *o*-IC_6H_4Me, treated with Cu powder at 225° for 1 hr. and then heated to 230° for 30 min., give 15% of *2-carboxy-6-nitro-2'-methylbiphenyl*, m. 162-3°. 2-Nitro-6-carboxy-2'-methylbiphenyl was resolved with quinine in 60% EtOH; crystn. 3 times from 50% EtOH gives a solvated *l-salt*, m. 135-40°, $[\alpha]_D^{25}$ −124.2° (0.05 g. in 15 cc. $CHCl_3$), and a dry *l-salt*, m. 168-71°, $[\alpha]_D^{25}$ −133.5° (0.05 g. in 15 cc. $CHCl_3$); the mother liquor yields a *d-salt*, m. 128-31°; the solvated salt m. 118-23°, $[\alpha]_D^{25}$ −105° (0.1 g. in 15 cc. $CHCl_3$). The *l-acid* m. 153.5°, $[\alpha]_D^{25}$ −65° (0.1 g. in 25 cc. EtOH); the *d-acid* m. 153-6°, $[\alpha]_D^{25}$ 61.5° (0.464 g. in 15 cc. EtOH). 2,3-$IMeC_6H_3CO_2$-Me and *o*-$IC_6H_4NO_2$ with Cu at 245-50° give 50% of *2-methyl-6-carboxy-2'-nitrobiphenyl*, pale yellow, m. 157°; brucine in MeOH gives a less-sol. salt, m. 165-7°, $[\alpha]_D^{25}$ 48° (0.05 g. in 15 cc. $CHCl_3$), and a more sol. salt, m. 153-60°, $[\alpha]_D^{25}$ −51° (0.05 g. in 15 cc. $CHCl_3$); the *d-acid* m. 179-81°, $[\alpha]_D^{25}$ 73.5° (0.05 g. in 15 cc. $CHCl_3$); *l-acid*, m. 175-9°, $[\alpha]_D^{25}$ −72.6° (0.0485 g. in 15 cc. $CHCl_3$). 6-Nitrodiphenic acid (I) yields *d*- and *l*-acids with $[\alpha]_D^{25}$ 39° and −37.5°. 2,3-$Br(O_2N)C_6H_3CO_2Me$ and *o*-$IC_6H_4NO_2$ with Cu at 220-5° give 30% of *2,2'-dinitro-6-carboxybiphenyl* (II), m. 164°; *quinine salts*, m. 195-7°, $[\alpha]_D^{25}$ 52.5° (0.05 g. in 15 cc. $CHCl_3$), and m. 121-5°, $[\alpha]_D^{25}$ −238° (0.1 g. in 15 cc. $CHCl_3$); the *d*-acid m. 135-7°, $[\alpha]_D^{25}$ 201.5° (0.1 g. in 15 cc. EtOH); the *l*-acid m. 127-30°, $[\alpha]_D^{25}$ −199.5° (0.05 g. in 15 cc. EtOH). The following values are for $[\alpha]_D^{25}$ and half-life period (in min.) in the solvent indicated: 2,6-$Me(HO_2C)C_6H_3C_6H_4NO_2$-2, 75.7° (0.1 g. in 15 cc. EtOH), —; 49.5° (0.1 g. in 20 cc. AcOH), 1075; 73° (0.1 g. in 20 cc. BuOH), 913. 2,6-$O_2N(HO_2C)C_6H_3C_6H_4Me$-2, 61.5° (0.0464 g. in 15 cc. EtOH), —; −65° (0.1 g. in 25 cc. AcOH), 179; −73.8° (0.1 g. in 25 cc. BuOH), 166. 2,6-$Me(O_2N)C_6H_3C_6H_4$-CO_2H-2, −68.4° (0.095 g. in 25 cc. EtOH), —; −86.6° (0.084 g. in 15 cc. AcOH), 2007; −72° (0.0583 g. in 15 cc. BuOH), 2510. I, 3.90° (0.05 g. in 15 cc. EtOH), —; −84° (0.1 g. in 20 cc. AcOH), 91; −27.2° (0.195 g. in 20 cc. BuOH), 101, 107; 293° (0.05 g. in 25 cc. 0.1 *N* NaOH), 4.6. II, 201.5° (0.1 g. in 15 cc. EtOH), 2000; 202° (0.07 g. in 25 cc. AcOH), 125; 218° (0.07 g. in 25 cc. BuOH), 91, 86; −93° (0.2 g. in 25 cc. 0.1 *N* NaOH), 91. The half-life periods do not correspond to what might be anticipated merely from the relative size of the groups as deduced from x-ray data or from the rates of racemization of previously studied biphenyls. The relative positions of the groups have a marked effect on the stability of the mole. The rate of racemization is modified by the solvent used. **XLIX. Comparison of the racemization rates of the 2,2',6'-nitro-, carboxy- and methoxy-biphenyls.** Roger Adams and G. C. Finger. *Ibid.* 2828-30.—2,3-$I(MeO_2C)C_6H_3OMe$ (5 g.), 4.3 g. *o*-$IC_6H_4NO_2$ and 10 g. Cu bronze, refluxed for 2 hrs. at 200° and the crude product refluxed with Na_2CO_3-NaOH in EtOH, give 5 g. of *2-methoxy-6-carboxy-2'-nitrobiphenyl* (I), m. 234-6°; 0.72 g. I gives 0.92 g. of the *brucine salt*, m. 222-5°, $[\alpha]_D^{25}$ −47.1° (0.106 g. in 20 cc. $CHCl_3$); the half-life period calcd. on the basis of a monomol. reaction is 99 ± 11 min.; dil. HCl gives *l*-I, m. 229-32°, $[\alpha]_D^{25}$ −213.3°, half-life period 371 min. 2,3-$Cl(O_2N)C_6H_3OMe$ (II) and *o*-IC_6H_4-CO_2Me at 275°, treated with Cu in 5-g. lots, followed by hydrolysis, give a mixt. of *2,2'-dimethoxy-6,6'-dinitrobiphenyl*, yellow, m. 226-8° (also prepd. from II and Ph-NO_2 with Cu bronze at 200-30°), and *2-methoxy-6-nitro-2'-carboxybiphenyl* (III), pale cream, m. 196-8°; the brucine salt m. from 70 to 90° and decomps. 108-25°, the salt had practically a 0 rotation and no mutarotation was observed over a period of several hrs.; hydrolysis with alkali gives the *l-acid*, m. 195-9°, $[\alpha]_D^{25}$ −127.9°, half-life period 219 min. (this value may be in error more than usual); hydrolysis with HCl gives an acid with a half-life period of 28 min. 2-Nitro-6-carboxy-2'-methoxybiphenyl proved to be unstable and the least stable of the 3.

C. J. West

The bitolyl series. VII. A. Angeletti. *Atti accad. sci. Torino, Classe sci. fis. mat. nat.* **72**, I, 373-7(1937); *Chem. Zentr.* **1938**, I, 3770; cf. *C. A.* **30**, 3426².—Passage from the biphenyl system to the fluorene system (cf. *C. A.* **32**, 4565⁴) is impossible when the compds. are tetra-*o*-substituted. In order to substantiate this statement further the decompn. of the diazonium derivs. of *2-chloro-2'-amino-6,6'-bitolyl* (I) and of *2-bromo-2'-amino-6,6'-bitolyl* (II) by water was studied. I was diazotized in 6% HCl with $NaNO_2$ at 0-4°. After diazotization the ppt. was filtered, washed and warmed on the water bath without allowing the temp. to rise above 90°. The red-brown resinous product was dissolved in ether, the ether

soln. washed with dil. NaOH, and the alk. soln. sepd. from the ether layer. Upon acidifying the NaOH soln. with HCl a red-brown ppt. was obtained which gave a slight amt. of yellow needles, m. 192° from petr. ether. These crystals could not be analyzed. After evapn., the ether soln. yielded a red-brown residue which was distd. with steam. The prisms from alc., m. 119°, were *2,2'-dichloro-6,6'-bitolyl*, $C_{14}H_{12}Cl_2$. The same compd. was also obtained when the diazonium soln. was poured into a soln. of CuCl in concd. HCl. II was diazotized in an analogous manner and decompd. with water to give *2,2'-dibromo-6,6'-bitolyl*, as prisms, m. 109–10°. W. A. Moore

3,3'-Dimethyl-4,4'-dihydroxybenzophenone. Max H. Hubacher. *J. Am. Chem. Soc.* **61**, 2664–5(1939).—Fusion of 10 g. *o*-cresolphthalein and 70 g. KOH at 260–5° (10 min.) gives 69% of *3,3'-dimethyl-4,4'-dihydroxybenzophenone* (I), m. 247–7.8°; NaOH or concd. H_2SO_4 gives a yellow soln.; *di-Ac deriv.*, m. 106.8–7.2°. Similarly, *o*-cresolbenzein gives 61% of I (Doebner and Schroeder, *Ann.* **257**, 74(1890), state that a compd. m. 138° is formed in this reaction). I (2.42 g.) and 5 g. Me_2SO_4 in 60 cc. *N* MeONa, refluxed 1 hr., give 0.85 g. of the *di-MeO deriv.*, m. 113.7–14.2° (*oxime*, m. 160.9–1.2°), and 1.6 g. of the *4-MeO deriv.*, m. 203.7–4.2°. Fusion of I with KOH at 280° for 110 min. gives *o*-MeC_6H_4OH and 3,4-$Me(HO)C_6H_3CO_2H$. C. J. West

Preparation of di-*o*-tolylchloromethane. Eugene B. Reid. *J. Am. Chem. Soc.* **61**, 3238(1939).—*Di-o-tolylchloromethane*, m. 70–1°, results in 90% yield from the carbinol in C_6H_6 and concd. HCl on standing 2 days. C. J. West

Synthesis of iodinated benzoylbenzoic acids and anthraquinones. Robert W. Higgins and C. M. Suter. *J. Am. Chem. Soc.* **61**, 2662–4(1939).—4,5-Diiodophthalic anhydride (I) (5 g.), 3.6 g. $AlCl_3$ (slight excess over 2 moles) and 40 ml. C_6H_6, refluxed 24 hrs., give 4.8 g. (80%) of *2-benzoyl-4,5-diiodobenzoic acid* (II), m. 244–5° (all m. ps. cor.); the 3,4-isomer of I gives 65% of the *3,4(?)-isomer* (III) of II, m. 223–4°; the yield was about the same after 9 hrs. heating; *3,6-isomer* (IV) of II, m. 218–20°, 60%. 3,4,6-Triiodophthalic anhydride (32.6 g.) gives a mixt. of *2-benzoyl-3,4,6-* (V) (16.3 g.) and *-3,5,6-triiodobenzoic acids* (VI) (14.4 g.), m. 257–8° and 225–7°, resp., I (2 g.), gradually added to 40 g. 100% H_2SO_4 at 140° during 30 min., cooling to 70–80° and addn. of ice, gives 80% of *2,3-diiodoanthraquinone*, m. 291–2°; *1,2-isomer*, from III, orange-red, m. 236–7°; *1,4-isomer*, from IV, m. 218–19°, 60%. *1,2,4-Triiodoanthraquinone*, m. 202–3.5°, results in 25% yield from 2 g. of either V or VI in 60 g. 100% H_2SO_4 at 105° (added over 30 min. and heated an addnl. 30 min.). $C_6H_4(CO)_2O$ could not be condensed with *m*-$C_6H_4I_2$. PhOMe and *o*- and *m*-MeC_6H_4OMe condense readily with I or the tetra-I deriv. Veratrole and 4-chloroveratrole do not condense with I derivs. of $C_6H_4(CO)_2O$. I was detd. by the Stepanow method, consistent results being obtained after digesting the AgI ppt. with dil. HNO_3 for several hrs. C. J. West

Triarylcarbinols. VII. 4'-Dimethylaminobiphenylyldiphenylcarbinol and its relation to the theory of color of dyes. Avery A. Morton and Wm. H. Wood. *J. Am. Chem. Soc.* **61**, 2902–5(1939); cf. *C. A.* **32**, 2524².—4-$Me_2NC_6H_4C_6H_4Br$-4 (4 g.) and 2 6 g. Ph_2CO in C_6H_6, refluxed 3 hrs. while 0.7 g. Na is added and then 15 hrs. longer, give 36% of *4'-dimethylaminobiphenylyldiphenylcarbinol* (I), m. 177–8°. This gives a strong red color with concd. H_2SO_4 and a yellow color with $HClO_4$ in AcOH; the absorption max. is at 484 mμ. Titration with $HClO_4$ showed that in the presence of I halochromism is not displayed until enough acid has been added to neutralize the basicity of the Me_2N group; in absence of this compd. it can be observed with the 1st drop of acid. These results are not in accord with those predicted from the carbenium theory of Ph_3CH dyes. The titration data show that trixenylcarbinol (II) is definitely stronger than such weak bases as $AcNH_2$ and $BzNH_2$ as contrasted with Ph_3COH which has been shown to be weaker. Of the 3 $O_2NC_6H_4NH_2$ the *m*-compd. is by far the strongest base. **(4-$Me_2NC_6H_4C_6H_4$)$_3$COH** from $BrC_6H_4C_6H_4NMe_2$ and Et_2CO with Na in C_6H_6 were not successful. Yields of II of 48% may be obtained from 19 g. *p*-ClC_6H_4Ph and 5 g. Et_2CO in 50 ml. C_6H_6 by adding 5 g. Na chips to the boiling soln. during 0.5 hr. and refluxing for an addnl. 12 hrs. Best yields (42–5%) of 4-$BrC_6H_4C_6H_4NMe_2$-4 were obtained when 10 g. of the amine, 9 g. MeOH and 3 g. concd. HCl were heated in sealed tubes 36 cm. long at 140–50° for 12 hrs. **VIII. Occurrence of color with trixenylcarbonium salts.** Avery A. Morton and L. F. McKenney. *Ibid.* 2905–8.—Trixenylcarbinol (I) in AcOH gives only a slight color when satd. with HCl; addn. of a few drops of H_2O gives a pronounced red color; removal of the H_2O by $CaSO_4$ decreases the color. Other compds., such as $MeNO_2$, MeCN, $HCONH_2$, $CO(NH_2)_2$, MeOH, $(ClCH_2CH_2)_2O$, HCONHPh, PhNHAc, also intensify the color. In all cases the intensity of color goes through a max. as the quantity of agent is increased. The action suggests a complex formation but only I could be crystd. from the solns. and the position of the max. absorption band was not displaced in the case of agents with which the color was intense. AcOH does not form a color with $HClO_4$ unless the soln. is heated. HNO_3 in AcOH produces a color with $MeNO_2$ but not with H_2O; $HClO_4$ and I in Ac_2O give a *perchlorate* (II), $(PhC_6H_4)_3CClO_4.HClO_4$, green, m. 219.5–20°; the C_6H_6 soln. is colorless but becomes colored on heating; the *sulfate*, $(PhC_6H_4)_3CHSO_4.H_2SO_4$, forms dark red crystals with green iridescence, which are hygroscopic; the *nitrate* is a red amorphous mass. Upon electrolysis of II in $MeNO_2$, $PhNO_2$ or AcOH, the cathode rather than the anode portion becomes colorless; this is also true for an AcOH soln. of I contg. H_2SO_4, a $MeNO_2$ soln. of Ph_3CClO_4 or the sulfate, nitrate and chloride of I. In the electrolysis of a dil. (colorless) soln. of II in $PhNO_2$, color appeared at the anode rather than at the cathode. The behavior is in agreement with the view that the triarylcarbonium ion, or triarylcarbinol, is not capable of being colored if the ClO_4 ion is removed by electrolysis and will appear colored once more when the ion is added. Electrolysis of crystal violet in $MeNO_2$ was poor; in this case the cation remained colored and was deposited and reduced on the Pt anode. The anode compartment became less colored from migration of the colored cation toward the cathode. C. J. West

Structure of fluorescein, sulfonefluorescein and some of their halogenated derivatives. R. B. Sandin, A. Gillies and S. C. Lynn. *J. Am. Chem. Soc.* **61**, 2919–21(1939).—The regulated bromination of fluorescein (I) gives the 4,5-di-Br deriv. (II). This behavior is believed to be an indication of ring stabilization. Formulas are proposed on the basis of a lactoid and a quinoid structure for I. In the case of sulfonefluorescein only a 4,5-di-Br deriv. (III) results; it is conceivable that ring stabilization is much more pronounced than in the case of I. 2,7-Dichlorofluorescein (IV) also gives a *4,5-di-Br deriv.* (V). Hydrolysis of II and III gives 2-bromoresorcinol (this may be distinguished from the 3-isomer by its behavior on sublimation; the 2-isomer sublimes much more readily in the form of long needles, whereas the 3-isomer forms colonies of compact crystals). Reduction of the tetra-Br deriv. of I in dioxane, concd. HCl and AcOH with $SnCl_2$ (refluxing 15–25 hrs.) gives *2,7-dibromofluorescein*, yellow, m. 300–1°; *diacetate*, m. 259°; hydrolysis yields 4-bromoresorcinol and what is believed to be *2-(5'-bromo-2',4'-dihydroxybenzoyl)benzoic acid*, m. 240–1°. Reduction of V gives IV. I in AcOH, refluxed with $SnCl_2$ and concd. HCl for 15 hrs., is unchanged; evidently $SnCl_2$ has a negligible effect on the conjugated system of double bonds as found in the quinoid form of I. It is suggested that these compds. have fixed structures according to the Mills and Nixon theory (*C. A.* **25**, 694). C. J. West

Effect of substitution on the dissociation of hexaarylethanes. VIII. The disproportionation of tri-*p*-tolylmethyl. C. S. Marvel, Wm. H. Rieger and Max B. Mueller. *J. Am. Chem. Soc.* **61**, 2769–71(1939); cf. *C. A.* **33**, 7770⁸.—(*p*-MeC_6H_4)$_3$CCl (I), carefully purified and treated with Ag in C_6H_6, gives a light orange soln. of the ethane; magnetic susceptibility measurements showed that this is dissocd. to the extent of at least 16 ± 2%

(0.08 *M* soln.); if the soln. is allowed to stand at 24–30° for a few hrs. the color disappears entirely and no free radical remains. The glassy residue from the distn. of the C_6H_6 in a mol. still at 85° and 10^{-4} mm. gives $(p\text{-MeC}_6H_4)_3\text{-CH}$; the residue (II) is polymeric in nature and may be $CH_2{:}C_6H_4{:}C(C_6H_4Me)_2$. Removal of HCl from I by C_5H_5N (refluxing 5 min. in a N atm.) leads to a polymer apparently identical with II; the color of the soln. is qual. indistinguishable from that of the free radical. These facts are used to explain the course of the disproportionation reaction. IX. **The disproportionation of hexa-*p*-alkylphenylethanes and the effect of *o*-, *m*- and *p*-alkyl groups on dissociation of hexaarylethanes.** C. S. Marvel, Max B. Mueller, Chester M. Himel and Julius F. Kaplan. *Ibid.* 2771–5.— $(p\text{-EtC}_6H_4)_3CCl$ and Ag in C_6H_6, shaken for 15 min., give a soln. contg. 17% of free radical (as detd. by magnetic susceptibility measurements); at 30° all of the radical disappeared in 24 hrs. That the color does not change (fade) appreciably during the disproportionation indicates that in the series above Me the quinoid hydrocarbon $MeCH{:}C_6H_4{:}C(C_6H_4Et)_2$ does not polymerize. The color of the soln. is qualitatively the same as that of the soln. obtained from the chloride and C_5H_5N. The dissocns. of higher derivs. are: Pr 21, iso-Pr 26, iso-Bu 27, *sec*-Bu 33 (all ±2). The rates of disproportionation are given as curves; the order of increasing stability of the various free radicals agrees exactly with the order of increasing dissocn. Hexa-*m*-tolylethane is stable more or less indefinitely; it exists to the extent of at least 40% as the free radical. $o\text{-MeC}_6H_4CClPh_2$ with Ag gives a stable ethane, which is dissocd. to the extent of 25%; thus 1 *o*-Me is more effective in producing dissocn. than are 3 *p*-Me groups. Directions are given for the prepn. of *p-tert*-BuC_6H_4Br in 60% yield. *p-Isopropylphenyldiphenylchloromethane* (I), m. 90–1°; *p-tert-butylphenyl analog* (II), m. 133–4°. The ethane from II does not undergo disproportionation, since there are no H atoms on the C atom attached to the ring; this ethane showed 8–9% dissocn. and that from I 8–10%. I and the *p*-Me analog show the disproportionation reaction but both decompd. more slowly than the corresponding tri-*p*-alkylphenylmethyl radicals. The effects of *o*- and *m*-substituents must be due in part to steric factors. The following *peroxides* were prepd.: *o-tolyldiphenylmethyl*, m. 148–9°; *p-isopropylphenyldiphenylmethyl*, m. 139–40°; *p-tert-butylphenyldiphenylmethyl*, m. 156–7°. The O absorption (%) on shaking the chloride with Ag in the presence of O is: $p\text{-MeC}_6H_4CClPh_2$, 4 min., 83, 15 min., 84; *o*-isomer, 7 min., 90; I, 10 min., 83, 30 min., 96; $(p\text{-EtC}_6H_4)_3CCl$, 10 min., 80, 15 min., 82; $(p\text{-iso-PrC}_6H_4)_3CCl$, 8 min., 90, 23 min., 93; $(p\text{-iso-BuC}_6H_4)_3CCl$, 15 min., 80; $(p\text{-}sec\text{-BuC}_6H_4)_3CCl$, 3 min., 83, 20 min., 90. The degree of dissocn. of the ethanes was measured by the magnetic susceptibility method; data are given for χ_a and α. Equations are given for the calcn. of the rate of decompn. of the ethanes.
C. J. West

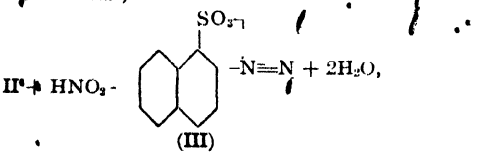
Synthesis of α-2-methoxyphenyl-β,β,β-triphenylethane. H. A. Iddles, K. S. French and E. F. Mellon. *J. Am. Chem. Soc.* **61**, 3192–4(1939).— Schorigin (*C. A.* **20**, 748; **21**, 579) postulated the structure $o\text{-Ph}_3CCH_2C_6H_4OH$ (I) for a compd. obtained as a by-product in the synthesis of $o\text{-MeC}_6H_4OCPh_3$ and by direct rearrangement of the ether on heating with Na. Parsons and Porter (*C. A.* **26**, 981) reported a synthesis of the Me ether (II) of I, m. 172° which was also obtained on methylation of I. Boyd and Hardy (*C. A.* **22**, 1970) questioned the structure of I. Details are given of the prepn. of I (m. 182–3°) and of its methylation to II (m. 162–3°), the properties of the Me ether agreeing with those of B. and H. $o\text{-MeOC}_6H_4CO_2H$ is electrolytically reduced in 54.7% yields to $o\text{-MeOC}_6H_4\text{-}CH_2OH$; $o\text{-MeOC}_6H_4CH_2Cl$ results in 27.5-g. yield from 34 g. of the alc. and concd. HCl in Et_2O; it was also prepd. with $SOCl_2$. $o\text{-MeOC}_6H_4CH_2MgCl$ and Ph_3CCl give *α-2-methoxyphenyl-β,β,β-triphenylethane*, m. 140–2°; this was also prepd. from the chloride and Ph_3CNa in Et_2O. This is not identical with II. This result supports the evidence of B. and H., who concluded that the migrating radical does not enter the side chain when $o\text{-MeC}_6H_4OCPh_3$ undergoes rearrangement.
C. J. West

Light-sensitive nitro compounds. VI. Some derivatives of nitronaphthalene with *o*- and *p*-substituents containing sulfur. N. N. Vorozhtsov, V. V. Kozlov and I. S. Travkin. *J. Gen. Chem.* (U. S. S. R.) **9**, 522–5(1939); cf. *C. A.* **32**, 4959⁵.—α-Nitro-β-naphthylamine (I) is best prepd. by nitration of acet-β-naphthalide. When I undergoes the Gattermann reaction with SO_2 in the presence of H_2SO_4, it gives *1-nitronaphthalene-2-sulfinic acid* (II), m. 119.5°. If HCl is used instead of H_2SO_4 in this reaction, the product is *1-chloronaphthalene-2-sulfinic acid*, m. 137.1°. II is moderately light-sensitive. Nitration of acet-α-naphthalide gives a mixt. of the 2- and 4-nitro derivs. These are best sepd. by dissolving the mixt. in 6% KOH, dilg., adding the ppt. to dry $PhNO_2$ and passing in a stream of dry HCl. Under these conditions, 1,4-nitronaphthylamine is obtained. By the Gattermann reaction this gives *1-nitronaphthalene-4-sulfinic acid*, m. 132.5°, which is oxidized by H_2O_2 to the corresponding sulfonic acid. Both these acids are weakly sensitive to light. *2-Nitronaphthalene-1-sulfonic acid* is prepd. by the Sandmeyer reaction from 2-naphthylamine-1-sulfonic acid. It is a hygroscopic yellow powder whose Hg, Fe and Ag salts are insol. It is not sensitive to light.
H. M. Leicester

The catalytic oxidation of naphthalene to phthalic acid anhydride. Eckhard Bonitz. *Z. physik. chem. Unterricht* **52**, 60–1(1939).—In a 150-cc. distn. flask place 4 g. naphthalene, 30 cc. of H_2SO_4 (93–96%), 13 g. H_2SO_4 (65% SO_3) and 0.5 g. Hg. The reaction is more rapid if the Hg is heated with 2 cc. H_2SO_4 until $HgSO_4$ forms before it is introduced. The yield is 30%.
F. E. Brown

Structure of some naphthalene, hydrindene and tetralin derivatives. R. B. Sandin and T. H. Evans. *J. Am. Chem. Soc.* **61**, 2916–19(1939).— The reaction of Br compds. with $SnCl_2$ and HCl is proposed as a method for detecting ring stabilization. The important point in connection with the work is that an arrangement in an aromatic compd. of a Br atom and an NH_2 group in such a way that they are sepd. by a double bond or a conjugated system of double bonds gives rise to a so-called "pos." Br atom. $1,2\text{-BrC}_{10}H_6NH_2$, on boiling 1 hr. with $SnCl_2$ in HCl, gives 90% $\beta\text{-C}_{10}H_7NH_2$, 90% of the Br being removed; $4,1\text{-BrC}_{10}H_6NH_2$ gives 90% of $\alpha\text{-C}_{10}H_7NH_2$ as does $2,4,1\text{-Br}_2C_{10}H_5NH_2$, 90% of the Br being removed. $1,3,2\text{-Br}_2C_{10}H_5NH_2$ gives 95% of $3,2\text{-BrC}_{10}H_6NH_2$ (I), 90% of the 1-Br being removed; I is recovered after boiling 10 hrs. 4,5-Dibromo-5-aminohydrindene in 0.5 hr. gives 80% of 4-bromo-5-aminohydrindene (II), m. 54–5°, 80% of the 6-Br being removed; a reaction period of 5 hrs. gives only 25% II; boiling II for 6 hrs. gives 30% of unchanged II. 5-Bromo-6-aminotetralin lost 60% of the Br in 1 hr.; the Ac deriv. in 2 hrs. gives 85% of 6-aminotetralin, m. 34–5°; $o\text{-BrC}_6H_4NH_2$ loses 56 and 75% of Br in 1 and 2 hrs., resp. The results indicate that the structures of the $C_{10}H_8$ derivs. are based on the Erlenmeyer formula and that the preferred structures for the hydrindene derivs. are based on the Mills and Nixon formula (*C. A.* **25**, 694). No definite conclusion was reached regarding tetralin.
C. J. W.

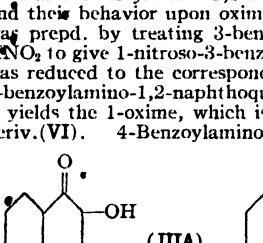
Two isomeric β-acetyldecahydronaphthalenes. Germaine Cauquil. *Compt. rend.* **209**, 441–3(1939).—Chlorination of decalin contg. both the cis and the trans stereoisomers yielded β-chlorodecalin, b_{18} 115°, d_4^{24} 1.0315, n_{5893}^{25} 1.4989, mol. refraction 49.09 (calcd. 48.84). By comparison with Ferrero and Kehlmann's data (*C. A.* **23**, 1407), the latter product is obviously a mixt. of cis form (b_{18} 110–12°) and trans form (b_{18} 120–22°). The product thus described was made to react with Mg in the presence of abs. Et_2O and when treated with AcH and worked up in the usual manner produced a methyldecahydronaphthylcarbinol, b_{14} 136–8°, d_4^{16} 0.9805, n_{5893}^{16} 1.49334, mol. refraction 54.06 (calcd. 54.74), in 45% yield. Attempts to fractionate the phthalate and phenylurethan derivs. of the alc. were unsatisfactory and hence the above alc. was oxidized to its corresponding ketone, b. 128–32°, with CrO_3 and AcOH. The latter ketonic stereo



mixt. when treated with semicarbazide-HCl + AcONa yielded a semicarbazone product which was separable into its components because of a differential soly. in abs. EtOH. The 2 ketonic forms regenerated from their semicarbazones yielded the following data: (*A*), b_{22} 142 3°, m. 27°, n_{5893}^{27} 1.4789, d_4^{27} 0.9542, mol. refraction 53.39 (calcd. 53.22), α 27° 39 dynes/cm., parachor 472 (calcd. 455); semicarbazone, m. 242°; oxime, m. 104°. (*B*), b_{22} 138°, n_{5893}^{27} 1.48348, d_4^{27} 0.9710, mol. refraction 53.01, α 27° 39.4 dynes/cm., parachor 463; semicarbazone, m. 196°; oxime, a liquid. W. A. Cook

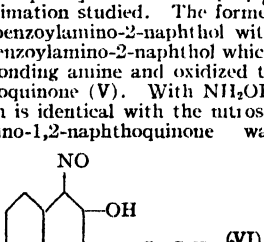
Reductive alkylation of aromatic primary amines. II. Wm. S. Emerson and W. D. Robb. *J. Am. Chem. Soc.* **61**, 3145–6(1939); cf. *C. A.* **32**, 8380⁶.—By use of the previous method (reducing the aniline and an aldehyde with Raney Ni and AcONa in EtOH), α-$C_{10}H_7NHEt$ was obtained in 88% yield and β-$C_{10}H_7NHEt$, β-$C_{10}H_7NHBu$, β-$C_{10}H_7NHCH_2Ph$, p-MeC_6H_4NHEt and p-MeC_6H_4NHBu were obtained in 50–64% yields. There was also isolated 19% of p-$MeC_6H_4NBu_2$. *N-Butyl-α-naphthylamine*, b_8 155–67°, d_{20}^{20} 1.001, n_D^{20} 1.5963, 80%; *HCl salt*, m. 151–2°. *N-Ethyl-p-anisidine*, b_{20} 135–40°, d_{20}^{20} 1.017, n_D^{20} 1.5444, 51%; *p-bromobenzenesulfonamide*, m. 113–14°. *N-Butyl-p-anisidine*, b_6 142–5°, d_{20}^{20} 0.963, n_D^{20} 1.5207, 65%; *HCl salt*, m. 187.5–8°. Benzyl-α-naphthylamine gives a *Bz deriv.*, m. 103–4°. p-$MeOC_6H_4NBu_2$ results in 25% yield. C. J. West

Reaction of a thiophene derivative with maleic anhydride. Daniel B. Clapp. *J. Am. Chem. Soc.* **61**, 2733–5(1939).—2,3,4,5-Di(1,8-naphthylene)thiophene (I) (from the fusion of acenaphthene and S) and maleic anhydride (II), heated for 15 min. at 225°, give 60% of *3,4,5,6-di(1,8-naphthylene)phthalic anhydride*, yellow, decomps. about 385°. I and stilbene, heated at 310–20° for 9 hrs., give 14% of *1,2-diphenyl-3,4,5,6-di(1,8-naphthylene)benzene*, greenish yellow, m. 290–1° (cor.), which has a pronounced yellow-green fluorescence in ultraviolet light. Thionessal does not react with II. C. J. W.



Reaction between diphenylketene and phenylacetylene. Lee Irvin Smith and Harvey H. Hoehn. *J. Am. Chem. Soc.* **61**, 2619–24(1939). Contrary to the statement of Staudinger (*C. A.* **2**, 102), 1.94 g. diphenylketene and 1.02 g. of PhC:CH, on standing 3 days at room temp., give 2.4 g. of *3,4-diphenyl-α-naphthol* (I), m. 143–4°; it is readily sol. in MeOH-KOH, gives a pos. PhOH reaction (Folin), contains 1 active H atom and does not add the Grignard reagent. In petr. ether the reaction is much slower and the yield is only 50%. I appears to exist in 2 forms, m. 143–4° and 154°. *Acetate* of I, m. 162–2.5°; *Me ether* of I, m. 203–3.5°; the Me ether in AcOH yields a *2-NO_2 deriv.*, yellow, m. 202°. I and $Pb(OAc)_4$ in AcOH, refluxed for 5 hrs., give *3,4-diphenyl-1,2-naphthoquinone* (II), orange-red, m. 249–50°. I could not be nitrated, the HNO_3 oxidizing I to II and uncrystallizable oils. $K_2Cr_2O_7$ in AcOH (refluxing 8 hrs.) gives BzOH and *o*-$BzC_6H_4CO_2H$. $KMnO_4$ or CrO_3 under mild conditions gives a product insol. in K_2CO_3, whose structure has not been detd. Reduction of II by Zn and AcOH or by $NaHSO_3$ gives colorless solns., which give II on allowing the Et_2O ext. to stand in the air. Reductive acetylation of II gives *1,2-diacetoxy-3,4-diphenylnaphthalene*, m. 166–7°. II and *o*-$C_6H_4(NH_2)_2$ give the *phenazine*, $C_{28}H_{18}N_2$, yellow, m. 274–5°. I couples with diazotized sulfanilic acid to give a red azo dye, reductive cleavage of which yields II. I and Br in Et_2O give the *2-Br deriv.* (III), m. 157–8°, which forms an *Ac deriv.*, m. 199–200°, and a *Me ether*, m. 209–10°. Oxidation of II with CrO_3 gives II. 1,4-Naphthoquinone and PhMgBr give *4-hydroxy-3,4-diphenyl-α-tetralone* (IV), m. 207°, to which Franssen (*C. A.* **19**, 3268) ascribed the structure 1,4-diphenyl-1,4-dihydroxynaphthalene; *oxime*, m. 196–7°. With AcOH-H_2SO_4 or Ac_2O IV yields I or its acetate. Oxidation of IV gives *o*-$BzC_6H_4CO_2H$, BzOH and a very small amt. of II. The reaction between diphenylketene and acetylenes appears to be quite general, although no solvent, or quite concd. solns. must be used in order to bring about a reaction. As yet the mechanism of the reaction is not known, but observations to be reported later indicate that an acetylenic H atom is not involved because Ph_2C_2 also reacts with the ketene. C. J. West

Synthesis of 2-nitronaphthalene-1-sulfonic acid. I. S. Travkin. *Wiss. Werke moskaut. mendelejeff. chem.-tech. Inst.* **1938**, No. 3–4, 73–5; *Khim. Referat. Zhur.* **2**, No. 1, 43(1939).—The object of the expt. was to det. whether or not 2-nitronaphthalene-1-sulfonic acid (I) possesses the same light sensitivity as the 1,2-isomer and its salts. The synthesis was performed according to the method of Sandmeyer, starting with 2,1-$H_2NC_{10}H_5SO_3H$ (II) (the amino acid of Tobias)



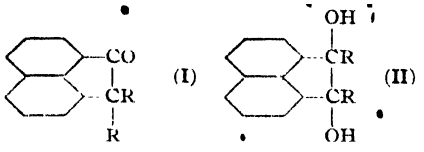
and III + $NaNO_2$ + catalyst → I + N_2. As catalyst $Cu_2SO_3.CuSO_3.2H_2O$ was used. The Na salt of the I is a yellow powder, very hygroscopic, sol. in water and in aq. alc. The investigation of the light sensitivity gave neg. results. W. R. H.

Oximation of some derivatives of β-naphthoquinone Henri Goldstein, H. Radanovitch, P. Kpetschet, O. Duboux, A. Kaehr, Ph. Gardiol and G. Genton. *Bull. soc. vaud. sci. nat.* **59**, 271–7(1937); *Chem. Zentr.* **1938**, I, 3466 7; cf. *C. A.* **32**, 2526². β-Naphthoquinone (I) reacts with NH_2OH to form the 2-oxime, which is identical with 2-nitroso-1-naphthol. Nevertheless, certain derivs. of I are known which, upon oximation, react in the 1-position. E. g., *4-amino-1,2-naphthoquinone* (II) reacts in alk. soln. to give the 1-oxime, an anomaly which is explained by assuming that the compd. reacts in the tautomeric form of 2-hydroxy-1,4-naphthoquinonimine It was shown that *4-anilino-1,2-naphthoquinone* (III) behaves like the 4-amino deriv., forming the 1-oxime. It can here be assumed that the substance reacts in the tautomeric *p*-quinoid form (IIIa). II and III are oximated in the 1-position even in acid soln., while *4-acetamino-1,2-naphthoquinone* reacts in the 2-position to form an oxime which is identical with *2-nitroso-4-acetamino-1-naphthol*. Analogous behavior is observed in the condensation reactions of I and its corresponding derivs., which form colored azines and oxazines. *5-Acetamino-1,2-naphthoquinone* reacts with NH_2OH to give an oxime identical with 2-nitroso-5-acetamino-1-naphthol, whereas the 1-oxime is not formed. Thus in I and its 4- and 5 AcNH derivs the CO group in the 2-position is most reactive, while in the 4-NH_2 and the 4-PhNH derivs. the most reactive group is that in the 1-position. In other words, I and its 5-AcNH deriv. possess an *o*-quinoid structure (which is also probable for the 4-AcNH deriv.), whereas the 4-NH_2 and the 4-PhNH derivs. are tautomeric compds. whose tendency to react in the *p*-quinoid form explains the resulting condensation in the 1-position. Oximation of *3-acetamino-1,2-naphthoquinone* (IV) gives the 1-oxime, which is identical with *1-nitroso-3-acetamino-2-naphthol*. *3-* and *4-Benzoylamino-1,2-naphthoquinones* were prepd. and their behavior upon oximation studied. The former was prepd. by treating 3-benzoylamino-2-naphthol with HNO_2 to give 1-nitroso-3-benzoylamino-2-naphthol which was reduced to the corresponding amine and oxidized to 3-benzoylamino-1,2-naphthoquinone (V). With NH_2OH V yields the 1-oxime, which is identical with the nitroso deriv. (VI). 4-Benzoylamino-1,2-naphthoquinone was

(IIIA)

(VI)

prepd. in an analogous manner by converting 4-benzoylamino-1-naphthol into the nitroso deriv., reducing this



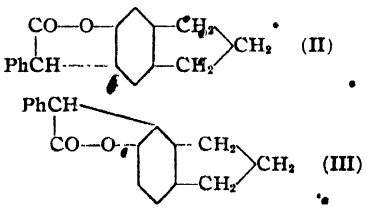
compd., and then oxidizing. The 2-oxime formed upon oximation is identical with *2-nitroso-4-benzoylamino-1-naphthol*. This compd. reacts in the normal manner, as the corresponding Ac deriv. does. In contrast to the behavior of these compds. is that of IV and V. This anomaly is attributed to steric hindrance. Probably in the derivs. of I the presence of a substituted group in the 3-position interferes with the reaction of the neighboring CO group, so that the CO group in the 1-position reacts in preference. The behavior of I itself is to be explained in an analogous manner: in the *o*-position to a CO group, the *o*-quinone ring contains as a substituted group the C chain forming the 2nd ring. Therefore a reduction in the reactivity of the CO group in the 1-position results and the CO group in the 2-position reacts in preference. W. A. Moore

Naphthoquinones of the vitamin K_1 type of structure. Louis F. Fieser, Wm. P. Campbell, Edward M. Fry and Marshall D. Gates, Jr. *J. Am. Chem. Soc.* **61**, 3216–23 (1939).—The synthesis of various allyl derivs. of α-naphthoquinone by utilization of the Claisen rearrangement reaction was undertaken to provide model substances of the structural types postulated for vitamins K_1 and K_2. One scheme tried without success consisted in the attempted addn. of a Grignard reagent to a naphthoquinone oxide. Details are given of the prepn. of the 2-Me and 2-Et derivs. of naphthoquinone in 29 and 39% yields, resp., and of the corresponding hydroquinones with $SnCl_2$ in HCl or with $Na_2S_2O_4$; the diacetates were prepd. by reductive acetylation with Zn and Ac_2O in C_5H_5N at 0°; the dibenzoates were similarly prepd. Oxides were prepd. by the use of 30% H_2O_2 in EtOH at 15°, followed by aq. Na_2CO_3; 2-Me (I), m. 95.5–6.5°; *2,6-di-Me* (II), m. 97–8°; *2,7-di-Me*, m. 91–2°. II and ClH_2CHCH_2-MgBr (III) did not give the expected 3-allyl deriv. but *2,6-dimethyl-1,4-naphthoquinone bromohydrin* (IV), m. 116–8°; IV also resulted in 73% yield from II and $MgBr_2$ in Et_2O; refluxing IV with AcONa in AcOH gives *3-bromo-2,6-dimethyl-1,4-naphthoquinone*, yellow, m. 114–14.5°. IV and III gives a small quantity of II, showing that the cleavage reaction is reversible. I and MeMgI give an oil which, boiled with concd. HCl in EtOH, gives the *compd.* $C_{17}H_{18}O_3Cl$, m. 141.5–2°; it decomps. when heated slowly. Attempts were made to introduce a β-unsatd. group by direct C-alkylation of a phenolic salt. 2-Methylnaphthohydroquinone (V) (2 g.), 4 g. $PhCH_2Cl$ and 20 cc. Me_2CO with 4 g. K_2CO_3, shaken at room temp. for 25 hrs., give 72% of the *dibenzyl ether* (VI), m. 74.5–5°; using 1 equiv. of $PhCH_2Cl$, 1 g. V gives 3 mg. of the *monobenzyl deriv.*, m. 159–60°, and 0.34 g. of VI. Refluxing 2 g. V and 4 g. $PhCH_2Cl$ with 4 g. K_2CO_3 in 20 cc. Me_2CO for 15.5 hrs. gives 0.3 g. of *2-methyl-3-benzyl-1,4-naphthoquinone*, (VIA), bright yellow, m. 107.5–8°. There was no indication of C-benzylation. V (3 g.), 10 cc. 2,3-dimethylbutadiene and 3 g. $(CO_2H)_2$ in 30 cc. dioxane, refluxed 24 hrs., give 29% of the hydroquinone (VIB) corresponding to VII and 15% of a *naphthotocopherol* (VIII), $C_{19}H_{20}O_2$, m. 73–3.5°, if $MeOCH_2CH_2OH$ is used as the solvent at 70°, 38% of V is recovered and the yield of VIB is decreased to 15%; some VIII also results. Oxidation of VI gives *2-methyl-3-(β,γ,γ-trimethylallyl)-1,4-naphthoquinone* (VIIa), bright yellow, m. 95–5.5°; crude VI with Ac_2O-AcONa gives the *naphthohydroquinone diacetate*, m. 119–20°; it also results from VII with Zn and Ac_2O in C_5H_5N, at 0°, together with the *acetate* of VIII, m. 128.5–9°. VIII forms no picrate or $C_6H_3(NO_2)_3$ deriv.; it is sol. in EtOH-KOH with a deep yellow color. V (3 g.), 1.54 g. $PhCH{:}CHCH_2OH$, 2 g. $(CO_2H)_2$ and 20 cc. dioxane, refluxed 22 hrs. and the hydroquinone oxidized with Ag_2O and Na_2SO_4 give 22% of *2-methyl-3-cinnamyl-1,4-naphthoquinone* (IX), bright yellow, m. 127–7.5°; EtOH-KOH in the cold gives an intense indigo-blue color which persists for 15 min. and then fades to a brown; Cl_3CCO_2H may be used in place of $(CO_2H)_2$; the *hydroquinone diacetate* m. 167.5–8°. The *Et analog* of IX m. 118–8.5° (9.4% yield); *hydroquinone diacetate*, m. 123.5–4.5°. Condensation of V and isoprene, oxidation with $FeCl_3$ and reductive acetylation give *2-methyl-3-γ,γ-dimethylallyl-1,4-naphthohydroquinone diacetate*, m. 104.5–5.5°. From V and $PhCH_2OH$ with $(CO_2H)_2$ in dioxane there resulted only a few mg. of VIA. VIA is inactive at a dosage level of 100 γ and the corresponding 3-trimethylallyl compd. is inactive at a level of 200 γ; IX is active at a dosage of 100 γ but not at 10 γ. C. J. West

The structure of "α,α'-binaphthyl," a by-product in the preparation of perylene. B. N. Lundin. *J. Gen. Chem.* (U. S. S. R.) **9**, 682–3 (1939).—In the prepn. of perylene according to Ger. pat. 386,040, as modified by Sharvin and Soborovskiĭ (cf. *C. A.* **23**, 4695) a by-product (I) (up to 50%) was isolated, which was considered to be α,α'-binaphthyl (II). After repeated crystn. I is obtained in yellowish needles from alc., m. 154°, which could not be rendered colorless by chromatographic purification. A comparison with pure II showed the difference of the 2 compds. The mixed m. p. is 138–40°. I yields a picrate, bright-red needles, m. 158°, whereas II does not give a picrate; I shows a bright yellow-green fluorescence and II a slight blue-violet one. These results and those of the elementary analysis indicate that I is 1,1'-binaphthylene 2,2'-oxide (cf. Brass and Patzelt, *C. A.* **31**, 6226⁹). Gertrude Berend

The condensation of acenaphthenequinone with monohydric phenols; cyclic pinacols; reduction and autoxidation products. Hélène Bogdan. *Ann. sci. univ. Jassy*, Pt. I, **25**, 645–79 (1939) (in French).—Condensation of acenaphthenequinone with phenols in concd. H_2SO_4 yields compds. of type I (6 equivs. of acid) and of the pinacol type (II) (1 equiv.). The latter undergo transformation to pinacolones. Compds. of type I with free OH groups are reduced by Zn + NaOH to the corresponding secondary alcs. which autoxidize to derivs. of a reduced naphthalic anhydride and finally to naphthalic anhydride derivs. These act as indicators (cf. phthaleins) in aq. soln. Acenaphthenequinone (III) (7.2 g.) + 12 g. *p*-cresol (IV) heated with 9 cc. H_2SO_4 yield 12 g. *anhydro-1,1-bis(2'-hydroxy-5'-methylphenyl)-2-oxoacenaphthene*, from toluene or xylene, m. 333°. III (10.8 g.) + 21 g. IV + 1.5 cc. acid yield 15 g. *anhydro-1,1-bis-(2'-hydroxy-5'-methylphenyl)acenaphthene-1,2-diol*, from alc., AcOH or toluene, m. 225°; pinacolone, from toluene, m. 333°. III (1.8 g.) + 3 g. α-naphthol (V) + 2 drops acid yield 2 g. *anhydro-1,1-bis(2'-hydroxynaphthyl)-2-oxoacenaphthene*, from toluene or xylene, m. 337°; 7.2 g. III + 12 g V with 200 cc. alc. and 80 cc. concd. HCl yield 10.5 g. *anhydro-1,2-bis(2'-hydroxynaphthyl)acenaphthene-1,2-diol*, from alc., m. 182°; *pinacolone*, from toluene, m. 337° III (3.6 g.) + 5 g. *as-m*-xylenol in 40 cc. concd. AcOH + 5 cc. concd. H_2SO_4 yield 4.8 g. *anhydro-1,1-bis(2'-hydroxy 3',5'-dimethylphenyl)-2-oxoacenaphthene*, from nitrobenzene, m. 350°, and *anhydro-1,2-bis(2'-hydroxy-3',5'-dimethylphenyl)acenaphthene-1,2-diol*, from acetone, m. 282°. III (3.6 g.) + 6 g. *m*-cresol with 35 cc. alc. and 20 cc. concd. HCl yield *di-m-cresolacenaphthenone*, from MeOH, m. 165°; *di-Ac deriv.*, m. 230°. III (3.6 g.) + 6 g. *o-cresol* with 100 cc. alc. and 36 cc. concd. HCl yield 5.6 g. *di-o-cresolacenaphthenone*, from alc. and chloroform, m. 216–17°; *di-Ac deriv.*, m. 105–20°(?). III (3.6 g.) + 6 g. *α-naphthol* + 100 cc. concd. HCl give a quant. yield of *di-α-naphtholacenaphthenone*, from MeOH and H_2O, m. 218° (decompn.); *di-Ac deriv.*, m. 192° (decompn.). III (3.6 g.) + 5 g. *o-xylenol* + a few drops concd. H_2SO_4 in AcOH yield *anhydro-1,1-bis(2'-hydroxy-4',5'-dimethylphenyl)-2-oxoacenaphthene*, from pyridine and acetone, m. 301°. III (3.6 g.) + 5 g. *p*-xylenol + 3 cc. concd. H_2SO_4 in AcOH yield *di-p-xylenolacenaphthenone*, from alc. and H_2O, m. 167–71° (alc. of crystn.), m. 247°; *di-Ac deriv.*, m. 198°. III (3.6 g.) + 6 g. thymol + 1 cc. concd. H_2SO_4 yield *dithymolacenaphthenone*, from toluene and ligroin, m. 195–7°; *di-Bz deriv.*, m. 107°. Reduction and autoxidation products: 4 g. diphenolacenaphthenone + 4 g. Zn + 40 cc. 5% NaOH after filtration, air oxidation and pptn. with concd. HCl yield *di(p-hydroxyphenyl)-2-carboxynaphthylcarbinol*, m. 239–40°, red-violet in alkali. Similar reduction of di-*o*-cresolacenaphthenone in H or CO_2 in a special setup yields *1,1-bis(3'-methyl-4'-hydroxyphenyl)-2-acenaphthol*, m. 117°. Air oxidation of di-*o*-cresolacenaphthenone and pptn. with concd. HCl

yield *di-o-cresoldihydronaphthalic anhydride* (VI), m. 230° (decompn.); *di-Bz deriv.*, m. 230°. VI absorbs O for several days to form *di-o-cresolnaphthalein*, m. under 100°. Reduction of di-α-naphtholacenaphthenone followed by autoxidation gives *di(4'-hydroxynaphthyl)-2-carboxynaphthylcarbinol*, m. 200° (decompn.), green in alkali; *di-Bz deriv.*, m. 180°. Reduction of di-*p*-xylenolacenaphthenone followed by autoxidation gives *di(2',5'-dimethyl-4'-hydroxyphenyl)-2-carboxynaphthylcarbinol*, m. 233° (decompn.), blue in alkali; *di-Bz deriv.*, m. 164°.



P. M. Apfelbaum

Labile union of oxygen and carbon: spontaneous dissociation of the photoöxide of diphenyldimethoxyanthracene. Charles Dufraisse, Léon Velluz and Mme. Léon Velluz. *Compt. rend.* 209, 516–18(1939); cf. *C. A.* 33, 6294⁷.—The spontaneous dissocn. in a closed vessel with evolution of O of the photoöxide of 9,10-diphenyl-1,4-dimethoxyanthracene is a unimol. reaction until about 1/3 of the O has been evolved; the rate then steadily decreases, probably on account of the photoöxide forming a solid soln. in the product of dissocn. The course of the reaction is unaffected by increase of the pressure of O to 140 atm. It is inferred that such dissocn. is irreversible which would imply that the O emitted by the photoöxide must be in a state of activity differing from that of ordinary O. Although this view was not supported by formation by such O of the photoöxide of tetraphenylnaphthacene, or any reaction with H_2, a pos. result was obtained with a photographic plate, the photoöxide causing a distinct blackening when in contact therewith, while no such result occurred with 4 other photoöxides which are not dissocd. in the cold. Possible explanations are discussed. C. A. Silberrad

1,2-Benzanthracyl-10-acetic acid. Alfredo Dansi and Cesare Ferri. *Ricerca sci.* 10, 178(1939).—Reaction of 1,2-benzanthracene with $ClCH_2CO_2Et$ in the presence of Cu powder gave after hydrolysis *1,2-benzanthracylacetic acid*, m. 273°; *Et ester*, m. 85°. Decarboxylation gave 10-methylbenzanthracene. The satd. water soln. of the Na salt contains 0.3%. Cf. *C. A.* 33, 7296¹. W. F. Bruce

The Mills-Nixon effect. Condensation of mandelic acid with 5-hydroxyhydrindene and with *ar*-tetrahydro-β-naphthol. B. I. Arventi. *Ann. sci. univ. Jassy*, Pt. I, 25, 692–8(1939)(in French).—Equal parts of mandelic acid (I) and 5-hydroxyhydrindene heated to 200–40° yield 50–55% of a lactone (II), from alc., m. 115° (corresponding acid, colorless oil, stable), and 1–2% of a lactone (III), from alc., m. 105° (acid, unstable); this shows a distinct M.-N. effect. I and *ar*-tetrahydro-β-naphthol, equal parts at 225–30°, yield 50% of a mixt. of equal parts of one lactone, structure like II, from alc., m. 110°, and another, structure like III, from alc., m. 140°; here there is no evidence of a M.-N. effect.

P. M. Apfelbaum

The anthraquinone group. II. Phthaloylation. Giunio B. Crippa and Raoul Caracci. *Gazz. chim. ital.* 69, 768–75(1939); cf. *C. A.* 27, 3463; 33, 4233⁷.—The phthaloylation of anthraquinone monoamines has not previously been recorded, although phthalimides have been prepd. by indirect methods. The present expts. were carried out to det. whether primary amines can be easily phthaloylated, for if so, the protection afforded the amine group would make possible various otherwise impracticable transformations. To correlate with earlier expts. (*C. A.* 33, 4233⁷), 1-amino-2-methylanthraquinone (I) was chosen as a starting material. I did not behave in the normal manner on phthaloylation, viz., $RNH_2 \rightarrow RN<\begin{matrix}OC\\OC\end{matrix}>C_6H_4$, but formed a phthalamide. I and $C_6H_4(CO)_2O$ (II) (equimol. wts.), maintained at 235° for 5 hrs., and the product purified from AcOH, yielded *(2-methyl-1-anthraquinonyl)-phthalamide* $C_6H_4[CONHC_6H_2Me(CO)_2C_6H_4]_2$ (III), orange, m. 221–2°, sol. in H_2SO_4. It and 5% aq. NaOH, refluxed for 2 hrs., and the ppt. extd. with Et_2O, yield I. The residue from the Et_2O extn. is Na (2-methyl-1-anthraquinonyl)phthalimidate, which, with mineral acids, forms the corresponding acid. III and Ac_2O (3 parts by wt.), refluxed for 4 hrs. (the soln. turns brown-red, then green-yellow), filtered and allowed to stand, ppt. *1-phthalimido-2-methylanthraquinone* $C_6H_4(CO)_2NC_6H_2Me(CO)_2C_6H_4$ (IV), light yellow, m. 261°, sol. in H_2SO_4 (repptd. by water). The mother liquor from the prepn. of V yields 1-acetylamino-2-methylanthraquinone, m. 176° (cf. *Ber.* 16, 699(1883)). IV and concd. H_2SO_4, heated at 100° for 8 hrs. (the soln. turns brown-red), poured into ice water, o-$C_6H_4(CO_2H)_2$ extd. by an alkali from the dark-red mass and the residue purified by AcOH, yield I. IV was not dehydrated by heating at various temps. up to 280° and for various times to 24 hrs. Up to 120° IV is not attacked by KOH, but above this temp. sapon. progresses at a rate which increases with the temp., e. g., at 185° in 2.5 hrs. it is completely transformed into K (2-methyl-1-anthraquinonyl)phthalimidate. At 225° for 5 hrs. a dark product was obtained, from which no definite compd. was isolated. IV, P_2O_5 and $PhNO_2$, refluxed for 24 hrs., do not react; not even prolonged heating of V with P_2O_5 gives any reaction. These results show the inertia of the Me H atoms in the intermol. dehydration. Furthermore dehydration between 2 mols., with formation of an ethylene bond as with 2-methylanthraquinone, does not take place. The impossibility of phthaloylating I in the normal way shows that only one of the amino H atoms is mobile, and that the other is so inert that it becomes reactive only with an energetic agent like Ac_2O. This must depend on a peculiar structure, which differs from that of all other aromatic amines. Possibly an oxime structure is formed from the keto-amine structure in the initial condensation reaction, i. e., tautomerism may be involved. The condensation reaction with 1-amino-2-phenylazomethine-(*C*)-anthraquinone (V) was next studied. In this case both amino H atoms are mobile and open to phthaloylation. Consequently the unsatd. azomethine group is a center of attraction which nullifies the CO group and reëstablishes the normal reactivity of the NH_2 group with II. V and II, heated at 240° for 3 hrs. (water is evolved), the product extd. with Et_2O, and the residue purified by $PhNO_2$, yield *1-phthalimido-2-phenylazomethine-(C)-anthraquinone*, $C_6H_4(CO)_2NC_6H_2(CH{:}NPh)(CO)_2C_6H_4$ (VI), violet-brown, m. 315°, sol. in C_6H_5N and $PhNH_2$. It colors cond. H_2SO_4 brown. The $PhNO_2$ mother liquor yields a relatively small amt. of *1-phthalimidoanthraquinone-2-aldehyde* (VII), brown-red with metallic reflection, m. 338°. When heated in $PhNH_2$ for 6 hrs. at 184°, VII forms VI. The formation of VII shows that the H_2O mol. which is liberated in the phthaloylation saponifies part of the V. C. C. Davis

Some derivatives of 1,2-benzanthraquinone-4'-sulfonic acid. Antonio Sempronj. *Gazz. chim. ital.* 69, 448–53 (1939).—Heller and Schulke prepd. a SO_3H deriv. (I) of 1,2-benzanthraquinone but did not identify either its constitution or that of its sulfonyl chloride or even describe the method of prepn. of the latter (cf. *C. A.* 3, 318; German pat. 263,340). The present work is concerned with the identification of I and the prepn. of various derivs. I was prepd. by the method of H. and S. and was

isolated as its K salt (II). This, heated with KOH (4 parts) at 260° for 15 min., the product dissolved in water, clarified, acidified with HCl and allowed to stand for a long time, ppts. successively BzOH and 5-hydroxy-2-naphthoic acid. This shows rupture of the quinone ring of I and that the SO_3H group is in the 4'-position. Hence I is *1,2-benzanthraquinone-4'-sulfonic acid*. This was confirmed by further expts. II (58 g.), PCl_5 (40 g.) and $POCl_3$ (200 g.), heated for 1 hr. at 120°, the $POCl_3$ distd., the residue poured onto ice and the ppt. dried *in vacuo*, and purified by PhMe and PhCl, yield 85% of *1,2-benzanthraquinone-4'-sulfonyl chloride* (III), m. 263°; its solns. in concd. H_2SO_4 are yellow, and when heated evolved HCl. III, heated at 275° until acid vapors are no longer evolved, the product dissolved in concd. H_2SO_4, poured into water, the dried ppt. extd. with AcOH, the ext. clarified and crystd., yields 4'-chloro-1,2-benzanthraquinone (IV), m. 230–1° (cf. Fieser, *C. A.*, **26**, 5300); its solns. in concd. H_2SO_4 are olive-green. IV is more readily prepd. by adding concd. HCl (170 cc.) dropwise to boiling aq. II (46 g. in 1200 cc.), then adding during 3 hrs. aq. $NaClO_3$ (40 g. in 200 cc.), heating for 2 more hrs. and purifying the ppt. by AcOH; the yield is 80%. II (54 g.), Zn (162 g.), concd. NH_4OH (435 cc.) and water (150 cc.), heated briefly at 50°, then for 10 hrs. at 85° (the mixt. turns red, then colorless), filtered, and the Zn in the residue destroyed by HCl, give 85-90% of *1,2-benzanthracene-4'-sulfonic acid* (V), insol. in org. solvents; its alk. salts are almost insol. in water, e. g., the soly. of the *K salt* is 1 g. in 2 l. V (5.5 g.), PCl_5 (4 g.) and $POCl_3$ (10 g.), allowed to stand for 1 hr., then heated for 1 hr. at 65–70°, poured onto ice, filtered, the dried residue extd. with anhyd. Me_2CO, the ext. clarified, evapd. and the product purified by PhMe and C_6H_6, yield 30% of *1,2-benzanthracene-4'-sulfonyl chloride* (VI), yellowish, m. 193°. It is decompd. by hot EtOH. VI (1.5 g.), dissolved in abs. EtOH (500 cc.) by standing for 3 weeks, filtered, dild. with water and allowed to stand for 24 hrs., ppts. *Et 1,2-benzanthracene-4'-sulfonate*, m. 157°. V and excess KOH, heated for 30 min. at 300°, digested in water, the filtrate acidified by HCl and the ppt. purified by C_6H_6, yield *4'-hydroxy-1,2-benzanthracene* (VII), m. 230°. With hot Me_2SO_4 and KOH in MeOH, VII forms *4'-methoxy-1,2-benzanthracene*, m. 163°. With Ac_2O and NaOAc, VII forms *4'-acetoxy-1,2-benzanthracene* (VIII), m. 193-4°. VIII (8.4 g.) in AcOH (100 cc.) and aq. $K_2Cr_2O_7$ (7.5 g. in 20 cc.), refluxed for 30 min., poured into water and the ppt. purified by C_6H_6 and dioxane, yield 80% of *4'-acetoxy-1,2-benzanthraquinone* (IX), silky yellow, m. 202–3°; its solns. in concd. H_2SO_4 are green. A soln. of IX in hot 2 *N* NaOH, acidified with AcOH, and the ppt. purified by xylene, yields *4'-hydroxy-1,2-benzanthraquinone*, red, m. 224-5°; its solns. in concd. H_2SO_4 are green.

C. C. Davis

Application of the Pschorr reaction to α-(*p*-xylylene)-2,5-di(6'-aminodimethylcaffeic acid). The synthesis of 9,10-dimethyl-2',3',6',7'-tetramethoxy-1,2,5,6-dibenzanthracene. Jack T. Cassaday and Marston T. Bogert. *J. Am. Chem. Soc.* **61**, 3058–61(1939).—K *p*-xylylene-2,5-diacetate (*C. A.* **31**, 6650[3]) and 6-nitroveratraldehyde in Ac_2O give 85% of *α-(p-xylylene)-2,5-di(6'-nitrodimethylcaffeic acid)*, pale yellow, decomps. above 300°; reduction with $FeSO_4$ and NH_4OH gives 50–60% of the *NH_2 deriv.* (I), pale yellow, decomps. above 300°; the diazo soln. gives a deep-purple soln. with H acid. Through the diazo reaction there results 66% of *α-(p-xylylene) - 2,5 - di(6' - hydroxydimethylcaffeic acid)*, pale brown, decomps. 245–55°; a Me ether could not be prepd. Distn. of the acid at 3 mm. and about 360° gives *2,5-di(2'-hydroxy-4',5'-dimethoxystyryl)-p-xylene*, decomps. 55–60° and becomes gummy in the presence of H_2O. The diazo soln. from I in dioxane stirred into NaH_2PO_2 in H_2O with some Cu powder gives 59% of *9,10-dimethyl-2',3',6',7'-tetramethoxy-1,2,5,6-dibenzanthracene-4,8-dicarboxylic acid*, decompg. 315–17°; refluxing with quinaldine and basic Cu carbonate for 6 hrs. (250°) gives 25–30% of *9,10-dimethyl-2',3',6',7'-tetramethoxy-1,2,5,6-dibenzanthracene* (II), pale yellow, m. 137–8° (cor.); its solns. exhibit a pale blue fluorescence; dry distn. of the acid with Cu powder alone was not suitable. II with HI or HBr did not yield a pure tetra-HO deriv., although some alc. exts. of the products gave green colors with $FeCl_3$; a *tetraacetate*, decompg. 300–50°, was obtained but not in sufficient quantity to saponify.

C. J. West

Reactions of tetrahydrophenanthrene. The synthesis of triphenylene and methyltriphenylene. W. E. Bachmann and W. S. Struve. *J. Org. Chem.* **4**, 472-9(1939).—In the Friedel-Crafts reaction phenanthrene (I) is usually substituted in the 3-position, sometimes in the 2-position. To obtain derivs. substituted in other positions, partially hydrogenated I is used, e. g., 9,10-dihydrophenanthrene gives 2-substituted derivs. (cf. Burger and Mosettig, *C. A.* **30**, 7570[6]). *1,2,3,4-Tetrahydrophenanthrene* (II), prepd. according to Haworth and Mavin (*C. A.* **27**, 501), is condensed in a Friedel-Crafts reaction with AcCl and with succinic anhydride (III). When 50 g. naphthalene, 25 g. III and 69 g. $AlCl_3$ in 190 cc. $PhNO_2$ react, 52 g. of a mixt. of *β-(1- and 2-naphthoyl)propionic acids* is obtained which is reduced by heating it with 100 g. amalgamated Zn, 75 cc. H_2O, 175 cc. concd. HCl in 100 cc. PhMe and 5 cc. AcOH for 24 hrs. with an addnl. 150 cc. concd. HCl being added in small amts. over this period. Distn. of the residue after evapg. the PhMe gives 38 g. of a mixt. of *γ-(1- and 2-naphthyl)butyric acids* (IV). When to a soln. of 38 g. IV in 200 cc. abs. Et_2O and 5 drops pyridine, 40 cc. SO_2Cl_2 is added and after standing for 0.5 hr. at room temp. the Et_2O and SO_2Cl_2 are distd. off, an oily acid chloride is obtained. This is dissolved in 200 cc. dry C_6H_6, cooled in ice and 30 cc. $SnCl_4$ is added and the mixt. allowed to stand in ice for 15 min. After hydrolysis of the addn. compd. with ice-cold dil. HCl, the C_6H_6 layer is washed with H_2O and dil. NH_4OH and the residue distd. at 0.4 mm. A mixt. of *1-* and *4-keto-1,2,3,4-tetrahydrophenanthrene* (V) in a yield of 26 g. is obtained. Reduction of V with amalgamated Zn, AcOH and HCl gives II in 70% yield. It m. 32.5–3.5°; *picrate*, m. 111° (cf. Schroeter and co-workers, *C. A.* **23**, 3703). When to a soln. of 13.5 g. $AlCl_3$ and 4.5 g. AcCl in 46 cc. $PhNO_2$, 10 g. II is added at −10°, the mixt. kept at 0° for 24 hrs., then decompd. with ice and HCl and the $PhNO_2$ removed by steam distn., 11.5 g. cryst. product, m. 45–50°, is obtained from which by vacuum distn. and recrystn. from MeOH-EtOH, 7.9 g. *9-acetyl-1,2,3,4-tetrahydrophenanthrene* (VI), m. 56.5–8°, is isolated. Dehydrogenation of VI by heating with S for 3 hrs. at 210–20° gives *9-acetylphenanthrene*, m. 70–3° (cf. *C. A.* **30**, 4852[2]), indicating that the Ac group actually is in the 9-position. This is further proved by the reduction of 1 g. VI with amalgamated Zn to *9-ethyl-1,2,3,4-tetrahydrophenanthrene* (VII), m. 22–4°; *picrate*, m. 124–6°. VII is also synthesized from 5.4 g. 1-ethylnaphthalene, 3.5 g. III and 8.5 g. $AlCl_3$, whereby 6.5 g. *β-[1-(4-ethylnaphthoyl)]propionic acid* (VIII), m. 129.5–31° after 3 crystns. from C_6H_6, is obtained. Reduction of VIII gives *γ-[1-(4-ethylnaphthyl)]butyric acid*, m. 115–16.5°, in 94% yield, which on cyclization with SO_2Cl_2 in pyridine yields *1-keto-9-ethyl-1,2,3,4-tetrahydrophenanthrene* (IX), m. 52–3°, in 77% yield. Reduction of IX with amalgamated Zn gives VII. Its pure *picrate* m. 125.5-6.5°. Dehydration of VII with Pd charcoal at 300–20° gives *9-ethylphenanthrene*, m. 63.5-4.5°, in 75% yield; *picrate*, m. 120.5-2.5° (cf. Mosettig and van de Kamp, *C. A.* **27**, 4792). Bromination of VI with Br in abs. Et_2O yields *ω-bromo-9-acetyl-1,2,3,4-tetrahydrophenanthrene* (X), m. 90.5–1:5°, in 72% yield. Condensation of X with $CHNa(CO_2Et)_2$ in C_6H_6 gives *β-[9-(1,2,3,4-tetrahydrophenanthroyl)]propionic acid* (XI), m. 167–9°, in 66% yield. XI is also obtained in 78% yield by the reaction of III with tetrahydrophenanthrene in the presence of $AlCl_3$. Reduction of XI with amalgamated Zn gives *γ-[9-(1,2,3,4-tetrahydrophenanthryl)]butyric acid* (XII), m. 133–4°, in 96% yield. Dehydrogenation of the *Me ester* of XII, prepd. with CH_2N_2, with Pd charcoal at 250–70° gives *γ-(9-phenanthryl)butyric acid* (XIII), m. 171–2°, in 90% yield (cf. Bergmann and Blum-Bergmann, *C. A.* **31**, 6646[4]). Cyclization of XIII with SO_2Cl_2 in pyridine gives

1-keto-1,2,3,4,9,10,11,12-octahydrotriphenylene (**XIV**), m. 121–2°, in 95% yield, which when reduced with amalgamated Zn gives *1,2,3,4,5,6,7,8-octahydrotriphenylene* (**XV**), m. 120.5–2°, in 74% yield; *picrate*, m. 193–5°. Dehydrogenation of **XV** with Pd charcoal at 300–20° gives *triphenylene*, m. 196.5–7.5° in 75% yield. Reaction of MeMgI prepd. from 0.56 cc. MeI and 0.19 g. Mg with 1.75 g. **XIV** gives 0.45 g. *1-methyl-1-hydroxy-1,2,3,4,9,10,-11,12-octahydrotriphenylene* (**XVI**), m. 104–5°, after 2 crystns. from C_6H_6-petr. ether. Heating of **XVI** with Pd charcoal for 2 hrs. at 300–20° gives *1-methyltriphenylene*, m. 93–4°, in 90% yield; *picrate*, m. 172.5–4°.

F. E. Brauns

Synthesis of phenanthrene derivatives. IV. 9,10-Cyclopenteno- and 9,10-cyclohexenophenanthrene. Charles K. Bradsher. *J. Am. Chem. Soc.* **61**, 3131–2 (1939); cf. *C. A.* **33**, 7777[1].—1-(2-Biphenylyl)-1-cyclopentene (2 g.) in Et_2O, cooled in an ice bath, treated with 0.019 mole of *o*-$HO_2CC_6H_4CO_3H$ in Et_2O and then allowed to stand 12 hrs. at room temp., gives the cyclopentene oxide; removal of the Et_2O, soln. in AcOH, addn. of 34% HBr and refluxing 24 hrs. give 0.31 g. of 9,10-cyclopentenophenanthrene [cf. Bachmann and Kloetzel (*C. A.* **32**, 539[9]) who did not obtain this compd. by the use of $AlCl_3$]. Similarly 3.4 g. 1-(2-biphenylyl)-1-cyclohexene gives 1 g. (30%) of 9,10-cyclohexenophenanthrene. C. J. W.

Synthesis of some new 1,4-dimethylphenanthrenes structurally related to morphol. Jack T. Cassaday and Marston T. Bogert. *J. Am. Chem. Soc.* **61**, 3055–7 (1939); cf. *C. A.* **33**, 8607[1].- K *p*-xylylacetate (32.4 g.), 33.5 g. 2-nitroveratraldehyde and 285 g. Ac_2O, heated 8 hrs. at 105–10°, give 67% of *α-(p-xylyl)-2-nitrodimethylcaffeic acid* (**I**), m. 205.5–6.5° (all m. ps. cor.); 2-nitroacetovanillin gives 50% of *α-(p-xylyl)-2-nitro-3-methoxy-4-acetoxycinnamic acid* (**II**), pale greenish tint, m. 211–14°. Reduction of **I** with $FeSO_4$ and NH_4OH gives 61–7% of the corresponding *2-NH₂ deriv* (**III**), a light-gray product which could not be purified; the *HCl salt* decomps. at 110°; **II** gives 80% of *α-(p-xylyl)-2-amino-3-methoxy-p-coumaric acid* (**IV**), lemon, m. 203–4°. Using the previously described method, **III** gives 50% of *1,4-dimethyl-5,6-dimethoxyphenanthrene-10-carboxylic acid* (**V**), m. 180.5–1.5°; the MeO groups could not be removed by HBr or HI, only black tars resulting. Similarly, **IV** gives 47% of *1,4-dimethyl-5-methoxy-6-hydroxyphenanthrene-10-carboxylic acid* (**VI**), which could not be purified; *Ac deriv.*, m. 170.5–1.5°. Distn. of 5 g. **V** and 1 g. Cu powder at 25 mm. gives 47% of *1,4-dimethyl-5,6-dimethoxyphenanthrene*, m. 73.5–4°; attempts to remove the Me groups failed; the CO_2H group could not be removed by refluxing with quinaldine and basic Cu carbonate. **VI** gives 42% of *1,4-dimethyl-5-methoxy-6-hydroxyphenanthrene*, m. 136.5–7°; the Me groups could not be removed by HBr or HI.

C. J. West

***o*-Quinone monoöxime inner complexes.** Helmut M. Haendler and Geo. McP. Smith. *J. Am. Chem. Soc.* **61**, 2624–6(1939); cf. *C. A.* **33**, 1558.- The following complexes were prepd. by treating a hot EtOH soln. of the oxime with an EtOH or H_2O soln. of a metallic acetate (or $NiCl_2$) and adjusting the pH with NH_4OH or AcOH until coagulation of the ppt. occurred. The ppts. were purified by extn. with EtOH. The complexes are extremely stable, sol. in warm glacial AcOH with decompn. and only slightly attacked by mineral acids in most cases. In addn. to the name of the color, the color plate reference of Maerz and Paul "Dictionary of Color" is given. Phenanthrenequinone monoöxime (**I**) derivs.: *Cd*, brownish orange (5-D-12), 80%; *Cu*, chocolate-brown (7-E-11), 80%; *Pb*, light-brown (7-C-12), 85%; *Mn*, yellowish brown (15-J-8), 80%; UO_2, with 2 moles EtOH, bright-yellow (9-L-8), 95%; heating at 100° splits off the EtOH, giving the UO_2 *deriv.*, brick-red (5-J-11), 90%. Chrysenequinone monoöxime (**II**) derivs.: *Cu*, red-brown (8-J-5), 80%; *Pb*, red-brown (8-J-7), 70%; *Mn*, olive-green (15-L-7), 95%; *Ni*, green-brown (16-A-12), 75%; UO_2, with 2 moles EtOH, yellow-orange (9-L-10), 80%; without EtOH, orange-brown (5-H-12), 75%. Cr, Hg, Pd, Rh and Zn also form complexes. Retenequinone monoöxime exhibits the same reactive tendencies as **I** and **II** but the colors are somewhat duller than those of **I** and not as dark as those of **II**.

C. J. West

Methyl homologs of triphenylene. Louis F. Fieser and Lloyd M. Joshel. *J. Am. Chem. Soc.* **61**, 2958–61 (1939).—In order to investigate the possibility that the introduction into triphenylene of suitably located alkyl groups might lead to carcinogenically active hydrocarbons, methods have been developed for the synthesis of the 1- and 2-Me and the 1,2- and 1,4-di-Me derivs. Details are given of the prepn. of *β*-(9-phenanthroyl)propionic acid (45% yield), *γ*-(9-phenanthryl)butyric acid (79% yield by the Clemmensen method) and 1-keto-1,2,3,4-tetrahydrotriphenylene (**I**) (87% by the use of HF at 0°). I with MeMgI, followed by dehydration at 200–20° and dehydrogenation with S at 230–50°, gives 42.5% of *1-methyltriphenylene*, m. 93.4–4.2° (all m. ps. cor.); *picrate*, orange, m. 177.2–8.2°. The Grignard reagent from 9-bromophenanthrene (**IA**) and methylsuccinic anhydride give 33% of *α-methyl-β-(9-phenanthroyl)propionic acid*, m. 155–6°; the structure follows from the alkali cleavage of the brominated compd. to 9-acetophenanthrene. Reduction gives 77% of *α-methyl-γ-(9-phenanthryl)butyric acid*, m. 136.6–7.4°; HF gives 92.5% of *2-methyl-1-keto-1,2,3,4-tetrahydrotriphenylene* (**II**), m. 85–6.5°; dehydrogenation with Pd-charcoal at 300–10° (N atm.) for 7 hrs. gives 73% of *2-methyltriphenylene* (**III**), m. 102.6–3.6°; *picrate*, light orange, m. 192.4–3°. Clemmensen reduction of **II** gives 77.5% of *2-methyl-1,2,3,4-tetrahydrotriphenylene*, m. 116.2–16.8°, which yields **III** on heating with Pd-C. Reaction of **II** with MeMgCl and heating the crude carbinol with Pd-C at 290–315° for 1.25 hrs. give 58% of *1,2-dimethyltriphenylene*, m. 86.8–7.4°; *picrate*, orange, m. 154–5°. The Grignard reagent of **IA** and MeOCH$_2$CN give 66% of *methoxymethyl 9-phenanthryl ketone*, m. 67.2–8°, b_3 220–5°. Reaction with MeMgCl yields 95% of *methylmethoxymethyl-9-phenanthrylcarbinol*, b_1 192–5°, m. below 0°; heating with $KHSO_4$ at 180° gives 58% of *α-(9-phenanthryl)propionaldehyde*, m. 66.2–7.2°; this reacts with $CH_2(CO_2H)_2$ in C_5H_5N-piperidine to give 80.5% of *γ-methyl-γ-(9-phenanthryl)crotonic acid*, m. 178.8–9.4°, which is reduced by Adam's catalyst (87.5% yield) to *γ-(9-phenanthryl)-valeric acid*, m. 83–5°; ring closure with HF at room temp. yields 82% of *4-methyl-1-keto-1,2,3,4-tetrahydrotriphenylene*, m. 99–100.5°, from which *1,4-dimethyltriphenylene*, m. 108.4–9.2°, results in 35% yield; *picrate*, orange-red, m. 148.4–9.4°.

C. J. West

The synthesis of derivatives of chrysene. W. E. Bachmann and W. S. Struve. *J. Org. Chem.* **4**, 456–63 (1939).— In a previous paper (*C. A.* **30**, 7570[1]) the prepn. of *β*-(2-phenanthroyl)butyric acid (**I**) for the synthesis of *2-methylchrysene* (**II**) was described. This synthesis is now completed. A mixt. of 2 g. **I**, 5 g. amalgamated Zn, 5.7 cc. AcOH, 7.5 cc. concd. HCl and 4 cc. PhMe is refluxed for 36 hrs. with the addn. of 10 cc. more HCl in small quantities during this period. The PhMe layer is evapd. and the oily residue sublimed at 0.4 mm. and 250°. Recrystn. of the sublimate gives 0.96 g. *γ-(2-phenanthryl)-β-methylbutyric acid* (**III**), m. 127.5–9°. When **III** is treated with SO_2Cl_2 and the resulting acid chloride is treated with $SnCl_4$, cyclization takes place with the formation of *2-methyl-4-keto-1,2,3,4-tetrahydrochrysene* (**IV**) in 86% yield. **IV** m. 141–2° after 2 crystns. from C_6H_6-petr. ether. Reduction of **IV** by refluxing 0.23 g. with 5 g. amalgamated Zn, 7.5 cc. AcOH, 7.5 cc. concd. HCl and 2 cc. PhMe for 24 hrs. gives *2-methyl-1,2,3,4-tetrahydrochrysene* (**V**), m. 141.5–2°, in 83% yield. Its *hemipicrate* m. 145.5–6°. Dehydrogenation of **V** by heating a mixt. of 0.18 g. with 0.03 g. Pd charcoal (cf. Zelinsky and Turowa-Pollak, *C. A.* **19**, 3053) at 300–20° for 1 hr. gives **II**, m. 224.5–5.5° (229–30°, cor.) in 90% yield. Its *picrate* m. 143–6°. 2-Propionylphenanthrene when reduced like **IV** yields *2-propylphenanthrene* (**VI**), which is isolated as its picrate in 83% yield. **VI** m. 35–6°; *picrate* m. 92–3°. 3-Propionylphenanthrene yields *3-propylphenanthrene* in 77% yield; *picrate* m. 107–8°. *γ-[2-(9,10-Dihydrophenanthryl)]butyric acid* (**VII**), m.

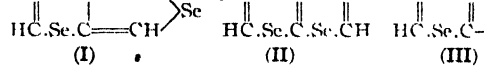
91–2°, is obtained in 92% yield by reduction of β-[2-(9,10-dihydrophenanthroyl)]propionic acid with amalgamated Zn in the same way as above. For the prepn. of γ-(*2-phenanthryl*)*butyric acid* (VIII), HCl is passed into 10 g. VII in 300 cc. MeOH for 0.5 hr. and the soln. refluxed for 1 hr. HCl is passed again into the cool soln. for 0.5 hr. and the soln. is refluxed for another hr., the MeOH is distd. off and C_6H_6 is added. The *Me ester* is washed with H_2O and the C_6H_6 distd. off. The residue is directly dehydrogenated by heating with Pd charcoal at 240–60° for 2 hrs. The residue is extd. with C_6H_6, the latter evapd., the residue hydrolyzed with hot 40% KOH and VIII ppt'd. with HCl in 90–95% yield. VIII m. 133–4° (Haworth and Mavin, *C. A.* **27**, 5329, found 134–5°). VIII is cyclized via its acid chloride in the same way as IV and gives *4-keto-1,2,3,4-tetrahydrochrysene* (IX), m. 125–6°, in 74% yield. When to 1 g. IX in 10 cc. dry C_6H_6 a Grignard reagent prepd. from 0.25 g. Mg and 0.75 cc. MeI in 10 cc. abs. Et_2O is added and the addn. decompd., 0.87 g. *4-methyl-4-hydroxy-1,2,3,4-tetrahydrochrysene* (X), m. 124–5°, is obtained. Dehydrogenation of X with Pd charcoal at 300–20° for 1 hr. gives *4-methylchrysene*, m. 149–9.5° (151–1.5°, cor.) in 92% yield; *picrate*, m. 131–5°. *4-Hydroxy-1,2,3,4-tetrahydrochrysene* (XI) is obtained when to a soln. of $(iso\text{-}PrO)_3Al$, prepd. from 1 g. Al, 25 cc. dry iso-PrOH, 5 drops CCl_4 and a pinch $HgCl_2$, 2.75 g. IX in 25 cc. PhMe is added. The mixt. is refluxed for 4 hrs., 25 cc. iso-PrOH is added and distd. off. The Al compd. is decompd. with 10% H_2SO_4, the PhMe layer sepd., washed with dil. NH_4OH and evapd. XI is obtained in 76% yield, m. 160–2°. Methylation of XI with MeOH and H_2SO_4 yields *4-methoxy-1,2,3,4-tetrahydrochrysene*, m. 79–80.5°, in 86% yield; the *Ac deriv.* of XI, prepd. by heating it with Ac_2O and pyridine, m. 119–20.5°. When HCl is passed into XI in cold dry C_6H_6 in the presence of $CaCl_2$, *4-chloro-1,2,3,4-tetrahydrochrysene* (XII) is formed in 80% yield. XII m. 115–17° (decompn.), then solidifies and remelts 174–8°. Refluxing of XII with pyridine gives *1,2-dihydrochrysene*, m. 58% yield, m. 182.5–4.5°; *picrate*, m. 155–6°. IX reduced with amalgamated Zn gives *1,2,3,4-tetrahydrochrysene* (XIII), m. 180.5–1.5°; *picrate*, m. 134–5.5°. Dehydrogenation of dihydrochrysene with Pd charcoal in a N atm. at 320° yields chrysene, m. 247–9°. This is also formed on dehydrogenation of XIII. F. E. Brauns

A new synthesis of picene. Nathan L. Drake and W. C. McVey. *J. Org. Chem.* **4**, 464–71 (1939). Alkylated picenes are found in the dehydrogenation products of many triterpenoids. The synthesis of picene derivs. is therefore of interest. A new synthesis of picene (I) which may lead also to the synthesis of alkylated I is described. *β-1-Naphthoylpropionic acid* (II) is prepd. according to a modified method of Fieser and Peters (*C. A.* **27**, 82) and m. 132–3°. Reduction of II by the Clemmensen method gives *γ-1-naphthylbutyric acid* (III), m. 107.5–8.5°. To convert III into *1-keto-1,2,3,4-tetrahydrophenanthrene* (IV), 50 g. III is suspended in 500 cc. dry C_6H_6, 50 g. PCl_5 is added with stirring, the mixt. is heated for 1.5 hrs., cooled to 0–5° and 34 g. anhyd. $AlCl_3$ is added at this temp. over a period of 30 min. The mixt. is allowed to warm up to room temp., kept overnight, then refluxed for 2.5 hrs. and, after cooling, it is poured into ice-cold HCl. IV is extd. with C_6H_6, washed with Na_2CO_3 soln. and distd. It b_1 145–50°. The yield is 81%. Its *2,4-dinitrophenylhydrazone* m. 283–5° (decompn.). *2-(β-Hydroxyethyl)toluene* (V), prepd. from *o*-BrC_6H_4Me and $(CH_2)_2O$ (cf. Dreger, *C. A.* **20**, 3280) in 62% yield, b_1 99–105°, d_{20}^{20} 1.0195, n_D^{20} 1.5349. *β-2'-Tolylethyl 3,5-dinitrobenzoate* m. 126–8°. *4-(β-Hydroxyethyl)toluene* (VI), prepd. from *p*-BrC_6H_4Me in 53% yield, b_1 100–6°, b. 235°, d_{20}^{20} 1.0008, n_D^{20} 1.5282; its *3,5-dinitrobenzoate* m. 147–9°. When to an ice-cold mixt. of 34 g. V in 61 g. $PhNMe_2$, 60 g. SO_2Cl_2 is added and allowed to stand overnight at room temp., then heated on a steam bath for 1 hr., the mixt. then decompd. with H_2O, extd. with Et_2O, washed with 5% Na_2CO_3 soln., dried and distd., *2-(β-chloroethyl)toluene* (VII) is obtained in 85% yield. VII b_1 80–4°, b. 223°, d_{20}^{20} 1.0553, n_D^{20} 1.5313. *4-(β-Chloroethyl)toluene* (VIII), prepd. in the same way as VII, b_1 81–5°, b. 222°, d_{20}^{20} 1.0370, n_D^{20} 1.5251. *3,4-Dihydro-1-phenethylphenanthrene* (IX) is prepd. by allowing a Grignard reagent prepd. from 6 g. Mg and 37 g. phenethyl bromide to react with 32 g. IV. After the reaction is complete, the mixt. is refluxed for 1 hr., the Et_2O distd. off until the soln. reaches 75° and refluxed for 5 hrs. The addn. compd. is decompd. with ice and HCl, extd. with Et_2O, and the ext. dried and distd. At 0.5–1 mm. and 185–7°, 24 g. IX is collected. Recrystd from EtOH, IX m. 62–3°. Its *sym-trinitrobenzenate* m. 91–2°. In a similar way *3,4-dihydro-1-(β-2'-tolylethyl)-phenanthrene* (X) is prepd. in 79% yield from VII, $b_{0.6-1}$ 190–5°, m. 57–8° after recrystn. from 95% EtOH; *trinitrobenzenate*, m. 101.5–2.5°. *3,4-Dihydro-1-(β-4'-tolylethyl)phenanthrene* (XI), prepd. from VIII, $b_{0.6-1}$ 200–5°, m. 79.5–81°; *picrate*, m. 101–2°. Dehydrogenation of IX by heating it with Pd charcoal (cf. Diels and Gaedke, *C. A.* **21**, 1649) at 300–20° gives a residue which is extd. with EtOH, the latter is concd. and the crude *1-phenethylphenanthrene* (XII) is dissolved in petr. ether and the soln. filtered through a 9-in. column of "hydralo." Recrystd. from MeOH, XII m. 86.5–9.5°. Its *trinitrobenzenate*, contg. 2 mols. $C_6H_3(NO_2)_3$, m. 149–51°. All attempts to cyclize XII by treatment with $AlCl_3$ in CS_2 have failed. Cyclization of IX with $AlCl_3$ in CS_2 yields 2.9 g. of a viscous oil, $b_{0.6-1}$ 205–15°. It solidifies after standing for several weeks without crystg. It is dehydrogenated with Pd charcoal at 300–400°, the residue first extd. with Et_2O, then with $CHCl_3$, the $CHCl_3$ ext. evapd., the residue extd. again with Et_2O and the insol. residue sublimed at 270–90°. Recrystn. from hot $CHCl_3$ gives I in 1% yield, m. 367–8.5°. Cyclization of X in the same way with $AlCl_3$ yields 7.5 g. of an oil, $b_{0.5-1}$ 205–10°, d_{20}^{20} 1.097, n_D^{20} 1.6440, which, when dehydrogenated with Pd charcoal at 380–400° and worked up as above, gives 230 mg. I, m. 367–9°. The Me group is split off in the cyclization process. Attempts to cyclize XI give an oil, $b_{0.6-1}$ 210–20°, from which on dehydrogenation no I can be isolated. F. E. Brauns

1,4-Dimesityl-2-phenyl 1,4-diketones. Robert E. Lutz and Charles J. Kibler. *J. Am. Chem. Soc.* **61**, 3010–12 (1939). The following series of compds. has been made in order to study the effect of terminal mesityl groups on the reactions of the satd. and unsatd. 1,4-diketone systems and on the ease of furan ring closure and ring fission. 1,4-Dimesityl-2-phenyl-1,4-butanedione (I) did not yield *2,5-dimesityl-3-phenylfuran* (II) by the usual procedure using Ac_2O and H_2SO_4; however 0.2 g. I and 1 cc. HI (d. 1.7), heated 1 hr. at 145–50°, gave 74% of II, and 1 g. I in 25 cc. AcOH and 1 cc. H_2O, refluxed gently and HCl passed through for 30 hrs., gave 0.87 g. of II, m. 154–5.5° (all m. ps. cor.); the 2-Ph group in I definitely facilitates furan ring closure as do the 2-Ph and 2-mesityl groups when substituted in CH_2Bz_2. II could not be oxidized with HNO_3 in AcOH; the product is the *4(?)-NO_2 deriv.*, m. 164–5°. Ditrimethylbenzoyl)ethylene and 3 equivs. of PhMgBr, refluxed for a few min., cooled to 0° and added slowly to I in Et_2O at 0–10°, gave 46% of *1,4-dimesityl-2-phenyl-2-butene-1,4-dione* (III), $C_9H_{11}COCH\ CPhCO\text{-}C_9H_{11}$, pale yellow, m. 109–10°; I may be substituted by quinone; reduction with Zn in AcOH gives I. III does not react with Ac_2O and H_2SO_4 at 50° and at higher temps. gives intractable resins; AcCl gives similar results but at 0–25°. C. J. West

1,4-Diphenyl-2-mesityl 1,4-diketones. Robert E. Lutz and Charles J. Kibler. *J. Am. Chem. Soc.* **61**, 3007–10 (1939). —The prepn. of this series of compds. was undertaken in order to study the effect of reactions of a mesityl group substituted directly at the ethylene linkage of the unsatd. 1,4-diketone system and to det. the effect of this group on the tautomerism of the corresponding triketone enol and hydroxyfuranone. $(CHBz)_2$ and $Me_3C_6H_2MgBr$ in Et_2O give 56% of *2,5-diphenyl-3-mesitylfuran* (I), m. 157.5–8°; there was no indication of the expected ketone, $BzCH_2CH(C_9H_{11})Bz$. The mesityl group not only offers no hindrance to furanization but actually facilitates the

reaction considerably. I reacts with PCl_5 on heating at 100° for 1 hr. or at 120° for 5 min., the product on hydrolysis giving largely I with some III; PBr_5 at room temp. gives a red oil, which yields 64% of IV on hydrolysis. I and HNO_3 in AcOH at 10° for 1 hr. give 90% of *cis-1,4-diphenyl-2-methyl-2-butene-1,4-dione* (*dibenzoylmesitylethylene*) (II), m. 98.5–9.5°. II is easily reduced by Zn in AcOH, $Na_2S_2O_4$ and catalytically, giving I. II and dry HCl in AcOH at room temp. gives 77% of the *4-Cl deriv.* (III) of I, m. 102.5–3.5°; with HNO_3 in AcOH at room temp. there results the *3-Cl deriv.* of II, m. 127.5–8°; reduction gives I. II and HBr in AcOH give 65% of the *4-Br deriv.* (IV) of I, m. 126–7°; this also results from II and PBr_5 at 0°; oxidation with HNO_3 gives the *3-Br deriv.* of II, m. 103–4.5°. II and Ac_2O-H_2SO_4 give 70% of the *4-AcO deriv.* of I, m. 124.5–6.5°. C. J. West



Reaction of tetrahydrofuran and 2,5-dimethyltetrahydrofuran with acyl halides. John B. Cloke and Frederick J. Pilgrim. *J. Am. Chem. Soc.* **61**, 2667–9(1939).—Tetrahydrofuran (I) and AcCl, boiled 12 hrs. and the recovered mixt. boiled an addnl. 12 hrs. (repeated twice), give 42.5% of $AcO(CH_2)_4Cl$ (II), a *compd.* $AcO(CH_2)_4O(CH_2)_4Cl$(?), b_{24} 165–7°, d_4^{20} 1.0471, n_D^{20} 1.44474, and a *compd.* $AcO(CH_2)_4O(CH_2)_4O(CH_2)_4Cl$(?), b_{10} 175–8°. I (50 g.) and 65 g. AcCl with 10 mg. $ZnCl_2$, refluxed 1.5 hrs., give 76% II; shorter refluxing or the use of more $ZnCl_2$ decreased the yield; $AlCl_3$ is not a suitable catalyst. I and EtCOCl with $ZnCl_2$ give 73% of *δ-chlorobutyl propionate*, b_{15} 93.5–4.5°, b_{20} 101.5–2.5°, d_4^{20} 1.0537, n_D^{20} 1.43640; PrCOCl gives 62% (heating 1.5 hrs.) of the *butyrate*, b_{15} 105.5–6.5°, b_{20} 112.5–13.5°, d_4^{20} 1.0302, n_D^{20} 1.43791; BzCl gives 54.5% of the *benzoate*, b_4 140–2°, d_4^{20} 1.1429, n_D^{20} 1.52028. I and AcBr did not give pure $AcO(CH_2)_4Br$; BzBr gives 76% of $BzO(CH_2)_4Br$, b_9 155–7°, d_4^{20} 1.3539, n_D^{20} 1.53694. The 2,5-di Me deriv. of I and AcCl give 77% of *α-methyl-δ-chloroamyl acetate*, b_{15} 85.5–7°, b_{20} 94–5°, d_4^{20} 1.0132, n_D^{20} 1.43288; AcBr did not give a pure Br analog. II (60 g.), 120 cc. MeOH and 0.7 cc. coned. HCl, heated at 40° for 3.5 days, give 80% of $Cl(CH_2)_4OH$. C. J. West

The cyclic acetals of furfural. Einar J. Salmi and I. J. Jansson. *Suomen Kemistilehti* **12B**, 28–30(1939)(in German); cf. *C. A.* **32**, 9051[3]. The following acetals of furfural were prepd. in C_6H_6 soln. with *p*-$MeC_6H_4SO_3H$ as a catalyst (the values after the b. p. refer to d_4^{20} and *n* at 20° for α, D, and β): *ethylene acetal*, $C_7H_8O_2$ (70% yield), b_{16} 91.0–3.0°, 1.1941, 1.48212, 1.48544 and 1.49385; *trimethylene acetal*, $C_8H_{10}O_2$ (yield practically quant.), b_{15} 111.8–16.5°, 1.1678, 1.48852, 1.49192 and 1.49987; *propylene 1,2-acetal*, $C_8H_{10}O_2$ (78% yield), b_{19-21} 97–9°, 1.1414, 1.47347, 1.47674 and 1.48495; and *butylene 1,3-acetal*, $C_9H_{12}O_2$ (yield practically quant.), b_{18-20} 121.5–2.5°, 1.1188, 1.48119, 1.48464 and 1.49230. S. A. Karjala

Secondary α-furfurylamines. J. E. Zanetti and J. T. Bashour. *J. Am. Chem. Soc.* **61**, 3133–4(1939).—Furfuryl bromide (*C. A.* **33**, 7779[1]) in Et_2O, added to an amine standing over crushed KOH, gives 50–65% yields, assuming the yield of the bromide to be 70% of the theory. *α-Furfurylmethylamine*, b_{761} 149–9.5°, d_{25}^{25} 0.992, n^{20} 1.4729 (HCl salt, m. 144–6°); *α-furfurylethylamine*, b_{761} 165–7°, d_{25}^{25} 0.963, n^{20} 1.4688 (HCl salt, m. 127–8°); *α-furfurylbutylamine*, b_{768} 198–200°, d_{25}^{25} 0.935, n^{20} 1.4669 (*HCl salt*, m. 189–91°); *α-furfurylamylamine*, b_{755} 214–16°, d_{25}^{25} 0.927, n^{20} 1.4668 (*HCl salt*, m. 185–8°); *α-furfurylphenylamine*, $b_{0.5}$ 109–10°, d_{25}^{25} 1.110, n^{20} 1.5834 (*HCl salt*, m. 150–1° (decompn.)). The aliphatic amines form picrates. C. J. West

Preparation of 2,5-dimethylpyrrole from the corresponding monocarboxylic ester. N. M. Timoshevskaya. *J. Gen. Chem.* (U. S. S. R.) **9**, 766(1939).—2,5-Dimethylpyrrole (I) has been obtained by heating 2,5-dimethylpyrrolecarboxylic ester with an excess of slightly moist soda lime in the presence of a small amt. of ether. A temp. of 80–90° is kept for 10–15 min.; it is then raised until distn. of H_2O starts. The distillate contains I in the form of an emulsion. Most of the distn. is carried out at 100–20°. The end temp. is 135–40°. I is extd. by means of ether, the ether ext. is washed with H_2O, dried over $CaCl_2$, the ether is evapd. and the residue is distd. *in vacuo*. I, b_{25} 78°, is obtained in 60–70% yield. In the same way, 2,4-dimethylpyrrole (yield 35%) has been prepd. from 2,4-dimethyl-3,5-pyrroledicarboxylic ester and 1,2,5-trimethylpyrrole (yield 20%) from 1,2,5-trimethylpyrrolecarboxylic ester. G. Berend

Dipole moment and structure of the isomeric selenophthenes. Bun-iti Tamamusi, Hazime Akiyama and Sumio Umezawa. *Bull. Chem. Soc. Japan* **14**, 318–22 (1939); cf. *C. A.* **33**, 9064[8].—Three isomeric selenophthenes, (I), (II) and (III), were obtained from the residue remaining after distn. of the selenophene from the crude product formed by the action of C_2H_2 on Se. I, which crystallizes from the residue after standing approx. 1 month, m. 123–4.5°, μ 1.07 × 10^{-18}; picrate, m. 163–5°; tetra-Br deriv., m. 246–7.5° (cor.). II, obtained by steam distn. of the filtrate from I, is an oil, b_{14} 93°, d_4^{25} 1.9354, n_D^{25} 1.6586, μ 1.52 × 10^{-18}; tetra-Br deriv., m. 271–2° (cor.); II does not form a picrate. III, which is not volatile with steam, m. 51–1.5°; picrate, m. 154–5.5°; tetra-Br deriv., m. 252.5–3° (cor.); $\mu \cong 0$. The structures of the isomers, as shown by dipole moment data, are as follows:

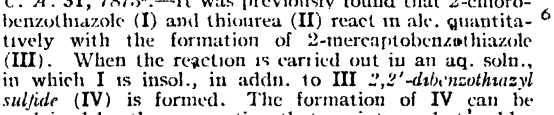
(I) (II) (III)

The dipole moment data are compared with those for the corresponding S compds. The values for mol. and sp. exaltation of II are −0.78 and −0.53, resp., differing in sign from the corresponding values for naphthalene and thionaphthene. George Ayers

Formation of 3-indoleacetic acid [from tryptophan] by ultraviolet irradiation. Albert Berthelot, Germaine Amoureux and Suzanne Deberque. *Compt. rend. soc. biol.* **131**, 1234–6(1939); cf. *C. A.* **32**, 4161[6]. That part of the spectrum between 220 and 234 mμ was most active in converting tryptophan to indoleacetic acid but some conversion was effected by wave lengths as long as 280 mμ. J. E. Gilson

Derivatives of coumaran. VI. Reduction of 2-acetobenzofuran and its derivatives. R. L. Shriner and John Anderson. *J. Am. Chem. Soc.* **61**, 2705–8(1939); cf. *C. A.* **33**, 8609[5].—2-Acetobenzofuran (I) and Br in CS_2 give 91% of the *ω-Br deriv.* (II), m. 90–1°; refluxing 25 g. of II with 50 g. $AcONa.3H_2O$ and 5 cc. of 6 *N* HCl in 500 cc. 50% EtOH for 1.5 hrs. gives 74% of the *ω-Ac deriv.* (III), yellow, m. 86–7°. Catalytic reduction of I with PtO_2 in EtOH at 2–3 atm. pressure for 6 hrs. gives a nearly quant. yield of 2-(1-hydroxyethyl)benzofuran (IV), b_{19} 147°, m. 41° (phenylurethan, m. 102–3°) (Stoermer and Shaffer, *Ber.* **36**, 2869, 2871(1903), give 37 and 126°, resp.). Catalytic reduction of IV or I with Raney Ni (14 and 36 hrs., resp.) gives 81 and 90% of 2-(1-hydroxyethyl)coumaran (V), b_{20} 145°, d_{25}^{25} 1.1138, n_D^{25} 1.5475 (phenylurethan, m. 115–16°; S. and S. give 73°). Hydrogenation in the presence of colloidal Pt gives a mixt. of 2-ethylbenzofuran and 2-ethylcoumaran, b_{19} 99–100°, and of IV and V, b_{19} 144–5°. This is further evidence that catalytic reduction of α,β-unsatd. ketones occurs by 1,2-addn. and not by 1,4-addn. as is the case on reduction by chem. means. Oxidation of V with CrO_3 in AcOH gives 2-acetocoumaran, whose semicarbazone m. 168–9°; this also results by Na-Hg reduction of I. III with PtO_2 in EtOH with H at 3 atm. pressure absorbs 1 mole equiv. of H in 10 min., giving I and AcOH; after 48 hrs. 1.8 mole equivs. of H are absorbed, giving a mixt. of I and its reduction products. III is not reduced in the presence of Raney Ni in cyclohexane and only slowly in EtOH at 2–3 atm. pressure. Na-Hg reduction of III in AcOH also results in a cleavage of the Ac group and the formation of a mixt. of the reduction products of I. It seemed possible that this cleavage reaction might be general for phenacyl esters but catalytic reduction of phenacyl acetate gives a good yield of *1-phenyl-2-acetoxy-*

ethanol, b_6 136–7°, d_{20}^{20} 1.1438, n_D^{20} 1.5260, and a very small quantity of PhMeCHOH and AcOH. C. J. West



Color in relation to chemical constitution of the organic and inorganic salts of isonitrosopyrazolones and isoxazolones. Sikhibhushan Dutt and Ione Nitravati Dharam Dass. *Proc. Indian Acad. Sci.* **10A**, 55–64(1939).—Isonitroso-3-methylisoxazolone (I) and isonitroso-3-phenylisoxazolone (II) are almost colorless, dissolve to colorless solns. in H_2O and org. solvents, but I forms intense magenta and II intense-violet salts with org. and inorg. bases owing to a change from the oximino-ketonic to the nitroso-enolic structures, confirming Dutt's theory of color (cf. *C. A.* **21**, 3194) based on mol. strain. The color change is sufficiently sharp and intense to make I and II excellent indicators. The corresponding isonitroso-3-methyl- (III) and -3-phenylpyrazolone (IV), although of closely analogous molecular structure to I and II, can exist in the less-strained oximino-enolic configuration and thus yield less intensely colored salts than I and II. I, II, III and IV are prepd. by new methods in much higher and purer yields than heretofore. I, recryst'd. from Et_2O, m. 150°; II, recryst'd. from H_2O, m. 130° (instead of 120°); IV, from H_2O, m. 188°; and III, from acetoacetic ester heated under reflux with $N_2H_4.H_2O$ and a little EtOH, cooled, filtered and satd. with N_2O_3 (from $NaNO_2$ and H_2SO_4), crystd. from boiling H_2O (yield 85% of theory), m. 217° (instead of 130° reported by Curtius).

A. P. Sachs

Synthesis of the isoxazole nucleus from fulminic acid and substances with triple bonds. Adolfo Quilico and Giovanni Speroni. *Ricerca sci.* **10**, 170–1(1939).—Fulminic acid with C_2H_2 and Me_2CO in acid medium condensed to give α-isopropenylisoxazole (I). The constitution of I was detd. by oxidation with CrO_3 to α-carboxyisoxazole and with $KMnO_4$ to α-acetylisoxazole, from which by MeMgI a carbinol was prepd. This substance on dehydration with P_2O_5 gave I. A mechanism for the reaction is suggested. A preliminary report.

W. F. Bruce

Reactions in the thiazole series. II. The reaction of 2-chlorobenzothiazole with thiourea in aqueous media. Geo. W. Watt. *J. Org. Chem* **4**, 436–41(1939); cf. *C. A.* **31**, 7873.—It was previously found that 2-chlorobenzothiazole (I) and thiourea (II) react in alc. quantitatively with the formation of 2-mercaptobenzothiazole (III). When the reaction is carried out in an aq. soln., in which I is insol., in addn. to III *2,2'-dibenzothiazyl sulfide* (IV) is formed. The formation of IV can be explained by the assumption that an intermediate addn. compd. (V) is formed which reacts with the 2nd mol. of I.

(V) (IV)

When 17 g. I and 7.6 g. II in 50 cc. H_2O are stirred for 80 hrs. and the white ppt. is washed with H_2O and 10% NaOH, 5.83 g. IV, m. 98.7–99.1° (cor.), is formed. From the alk. washing after extn. with Et_2O and acidification, 0.55 g. III, m. 179.2–80° (cor.), is isolated. By changing the exptl. conditions, such as concn., time, temp. and the nature of the reaction medium, it is possible to direct the reaction in such a way that either III or IV predominates. The variation of these conditions is studied in detail. When the reaction is carried out in liquid NH_3 at −33.5° or at room temp. in the presence or absence of NH_4Br, no I or II is formed. It has been shown that the formation of IV is dependent upon the formation and ionization of the intermediate addn. compd. F. E. Brauns

Synthesis of 4-methyl-5-hydroxyethylthiazole and its homologs. A. G. Pesina. *J. Gen. Chem.* (U. S. S. R.) **9**, 804–13(1939).—$AcCH_2CH_2CH_2OH$ (28 g.) in 140 ml. H_2O was treated dropwise with 43.8 g. Br at room temp. while stirring for 2–3 hrs. The aq. reaction layer was extd. with Et_2O, the ext. dried over Na_2SO_4, the Et_2O distd. off and $AcCHBrCH_2CH_2OH$ (I) obtained in 49.7% yield. I is unstable and decomps. on keeping. $HCSNH_2$ (II) was obtained from $HCONH_2$ and P_2S_5 in 36% yield as oil which crystallizes after purification, m. 28–9° (yield 16–18%). $MeCSNH_2$ (III), m. 106–8°, was prepd. by heating a mixt. of 5 moles $AcNH_2$ and 1 mole P_2S_5 with 4–5 parts benzene on a water bath for 5–10 min. The benzene layer is decanted and the residue extd. again with boiling benzene. This process is repeated until the benzene ext. is colorless. Yield 35–40%. $EtCSNH_2$ (IV), m. 41–3°, from $EtCONH_2$ and P_2S_5 in 5–6% yield. $PrCSNH_2$ (V), from 14 g. $PrCONH_2$ and 7.2 g. P_2S_5 in 50 ml. benzene on heating on a water bath for 30 min. Crude I (22 g.) and 9.5 g. crude II in 7 ml. alc. are kept overnight at room temp., then heated for 1 hr. on a water bath, after which time 40–50 ml. H_2O is added. The mixt. is extd. with a little Et_2O, then 35 g. KOH is added and 4-methyl-5-hydroxyethylthiazole (VI), b_{5-6} 116–17°, d_4^{24} 1.1890, n_D^{24} 1.5420, is extd. with Et_2O. Yield, 28–30%. Picrate, m. 160–2°; picrolonate, m. 179°. To a soln. of 11.6 g. Na in 50 ml. abs. alc. are added within 1 hr. 65 g. $AcCH_2CO_2Et$ and 100 g. $BrCH_2CH_2Br$ and the mixt. is warmed for 10 hrs. while stirring continuously. The mixt. is neutralized with alc. HCl. The NaBr is pptd. with 350–400 ml. abs. Et_2O and filtered off. The filtrate is evapd. *in vacuo* at 28–30°. $AcCH(CH_2CH_2Br)CO_2Et$ (VII), b_{5-6} 67–75°, d_4^{22} 1.0899, is obtained in 39.6% yield. VII (20 g.) is shaken with 13 g. SO_2Cl_2 at 0° for 40 min. Shaking is continued until a temp. of 20–5° is reached. Then 50 ml. Et_2O is added and the mixt. is heated until the evolution of SO_2 and HCl ceases. The Et_2O is distd. off and the residue distd. *in vacuo* to give $AcCCl(CH_2CH_2Br)CO_2Et$ (VIII), b_{7-9} 119–23°, in 79.8% yield. To 18 g. VIII is added a mixt. of 36 ml. glacial AcOH and 36 ml. 15% H_2SO_4 and the whole boiled for 4 hrs. An equal amt. of water is added to the reaction mixt. which is then extd. repeatedly with Et_2O. $AcCHClCH_2CH_2OH$ (IX), b_{6-9} 90–103°, d_4^{28} 1.1921, n_D^{25} 1.4605, is obtained in 20.7% yield. Crude II (1.8 g.) is caused to react with 2.8 g. IX, first at room temp., then on the water bath, and H_2O is added to the mixt. which is extd. with Et_2O. The aq. layer to which 3 g. KOH is added is extd. with Et_2O whereby VI is obtained in 4.6–5.1% yield. VI is also obtained in 2.3% yield from $AcCHNaCO_2Et$ + $BrCH_2CH_2OH$ → $AcCH(CH_2CH_2OH)CO_2Et$ + SO_2Cl_2 → $AcCCl(CH_2CH_2OH)CO_2Et$ + H_2SO_4 + AcOH → $AcCHClCH_2CH_2OH$ + II → VI. To 11.2 g. I is added 6 g. III in 25 ml. abs. alc. while cooling. The mixt. is heated on a water bath, 30 ml. H_2O is added, the mixt. is extd. with Et_2O, 20 g. KOH is added to the aq. layer which is then extd. with Et_2O. 2,4-Dimethyl-5-hydroxyethylthiazole, b_{7-8} 130–1°, d_4^{20} 1.150, n_D^{20} 1.5325, is obtained in 11.2% yield. It is easily sol. in H_2O, alc., Et_2O and gives a picrolonate, m. 139–40°. 4-Methyl-2-ethyl-5-hydroxyethylthiazole, b_{8-9} 133–6°, d_4^{24} 1.102, n_D^{24} 1.5220, is obtained from 5.2 g. I and 3.4 g. IV. It is easily sol. in alc. and Et_2O, slightly sol. in H_2O, and yields a picrolonate, m. 149–51°. 4-Methyl-2-propyl-5-hydroxyethylthiazole, b_{8-9} 140–2°, is obtained from 6.4 g. I and 4.6 g. V. $AcCH_2CH_2OH$, prepd. according to Ger. pat. 223,207, b_{15-6} 90–3°, d_4^{24} 1.1089, n_D^{24} 1.4585, in aq. soln. on treatment with Br gives $AcCHBrCH_2OH$ (X), unstable oil, d_4^{22} 1.66, n_D^{25} 1.505, in 23.7% yield. X (0.9 g.) and 0.65 g. II yield 4-methyl-5-hydroxymethylthiazole, liquid, n_D^{25} 1.5435, in 7.2% yield. It is easily sol. in H_2O, alc. and Et_2O and gives a picrolonate, m. 196–7°, insol. in alc. and $CHCl_3$.

Gertrude Berend

Dihydro-1,4-pyrans. VI. Opening and closing the ring. R. C. Fuson, R. E. Christ, and C. K. Bradsher. *J. Org. Chem.* **4**, 401–9(1939); cf. *C. A.* **31**, 6869.—Dihydro-1,4-pyrans (I), $ArC{:}C(CN).CH_2.CH_2CH(COAr).O$, may behave as vinyl ethers and the opening of the ring by acids should offer no difficulty. Derivs. of I in which Ar = Ph, *p*-MeC_6H_4 or *p*-$MeOC_6H_4$ have, however, proved refractory and *2-mesityl-5,6-dihydro-1,4-pyran-6-carboxylic acid* (II) is found to be a more tractable type of I having properties similar to those of I; but II

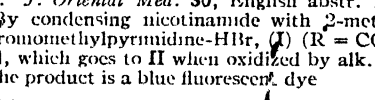
also can undergo ring opening when heated with MeOH and H_2SO_4, while on heating the open-chain *α-hydroxy-(2,4,6-trimethylbenzoyl)valeric acid* (III) is cyclized again. III is prepd. by addn. of 1.7 g. 2,3,6-$Me_3C_6H_2COCl$ to a mixt. of 0.23 g. Na in 10 cc. abs. EtOH, 50 cc. dry Et_2O and 3.26 g. Et α-hydroxysorbate (IV). The *Et α-hydroxy-δ-(2,4,6-trimethylbenzoyl)sorbate* (V) is obtained in 2.7-g. yield and m. 109°. V (23 g.) in 100 cc. EtOH is hydrogenated in the presence of 1 g. Raney Ni at 40-lb. pressure for 5 hrs. The solns. from 3 hydrogenation expts. are combined and concd. and the residual oil is refluxed for 12 hrs. with 700 cc. 10% Na_2CO_3 soln. and the cooled mixt. extd. with Et_2O. After acidification of the aq. soln., II is extd. with Et_2O, dried, evapd. and the residue distd. at 20 mm. in 44% yield, m. 149–50°. II cannot be hydrogenated either with Ni, Pd or Pt at 70° or by means of Na-Hg. Reduction of II with red P and HI yields adipic acid. Alk. H_2O_2 has no effect on II. O_3 or dil. HNO_3 with II gives 2,4,6-$Me_3C_6H_2CO_2H$, m. 152°. Bromination of II in CCl_4 yields a *mono-Br acid*, m. 139°. Nitration of II in H_2SO_4 forms *2-(3,5-dinitromesityl)-3-nitro-5,6-dihydroxy-1,4-pyran-6-carboxylic acid*, m. 250° (decompn.), which contains some H_2O of hydration which is removed by repeated crystn. from C_6H_6; it then m. 255° while its *Me ester* (VI) m. 162–3°. Esterification of II by refluxing 10 g. with 200 cc. MeOH and 7 cc. concd. H_2SO_4 gives 6.5 g. *Me α-hydroxy-δ-(2,4,6-trimethylbenzoyl)valerate* (VII), m. 43–4°. VII can be distd. unchanged under reduced pressure. III with α-naphthyl isocyanate gives a *urethan*, m. 145–6°. Oxidation of the Me ester (VIII) of III with alk. $KMnO_4$ followed by nitration with HNO_3 and H_2SO_4 gives 2,4,6,3,5-$Me_3(O_2N)_2C_6CO_2H$, m. 230 1°, while with fuming HNO_3, 2,4,6,3-$Me_3(O_2N)$ C_6CO_2H, m. 181–2°, is formed. Nitration of VIII with HNO_3 and H_2SO_4 yields VI. Treatment of VIII with PhMgBr gives a condensation product, m. 134–5°. With liquid NH_3 the *amide* of III, m. 111.5–12.5°, is formed. Hydrogenation of V by means of Adams' catalyst (cf. *C. A.* **22**, 1715) in acid abs. EtOH yields 10–15% II and an oil. The latter is dissolved in Na_2CO_3, the soln. faintly acidified with HCl and refluxed with *p*-phenylphenacyl bromide in EtOH for 1 hr. Addn. of H_2O ppts. the *p-phenylphenacyl δ-(2,4,6-trimethylbenzoyl)valerate*, m. 79°. In another hydrogenation expt. the residual product is fractionally distd. and the highest-boiling fraction sapond. separately with 10% KOH. From the acidified mixt. a *keto acid* is obtained which must be $Me_3C_6H_2CH(OH)(CH_2)_3COCO_2H$, m. 81°, since an ε-keto group cannot form a phenylhydrazone owing to steric hindrance. Its *phenylhydrazone* m. 103–4°. *δ-(2,4,6-Trimethylbenzoyl)valeric acid* (IX) is prepd. by slow addn. of a soln. of adipic anhydride, from 70 g. acid, to a mixt. of 150 g. $AlCl_3$, 350 cc. $PhNO_2$, 200 cc. CS_2 and 140 cc. mesitylene at 10° and stirring the mixt. for 14 hrs. at room temp. After decompn. with ice and steam distn. the residual oil is taken up in Et_2O and washed with HCl and 5% KOH. Acidification of the alk. soln. gives 35 g. IX, m. 60°. From the Et_2O soln. on evapn., 18 g. *1,4-di-(2,4,6-trimethylbenzoyl)butane*, m. 106° (cf. Kao, *C. A.* **29**, 4756[3]), is isolated. Bromination of IX yields *δ-bromo-δ-(2,4,6-trimethylbenzoyl)valeric acid*, m. 90–2°, which on oxidation with $KMnO_4$ gives succinic acid, m. 182°, and mesitylglyoxylic acid, m. 117°. F. E. Brauns

The chemistry of vitamin E. XIII. Specificity and relationship between chemical structure and vitamin E activity. H. M. Evans, O. H. Emerson, G. A. Emerson, Lee Irvin Smith, H. E. Ungnade, W. W. Prichard, F. L. Austin, H. H. Hoehn, J. W. Opie and S. Wawzonek. *J. Org. Chem.* **4**, 376–88(1939); cf. *C. A.* **33**, 7791[6].—The compds. so far tested for vitamin E activity are listed in a table grouped in classes as follows: chromans including tocopherols, coumarans, coumarins, coumarones, *o*-allylic phenols, quinones and hydroquinones, alcs. and ethers of phenols and hydroquinones. From a comparison of these compds. it seems that the probable requirements to show vitamin E activity are: a certain structural element must be present with the function of a ready conversion of a substance into an oxidation-reduction system with a potential within certain limits; further accessory groups of such a nature must be present that the compd. has the proper fat soly. so it can be absorbed and transported to the place where it is to be used; and it must be assumed that the organism can carry out the necessary biol. transformations such as cleavages, hydrolyses, dehydrations, hydrations, dehydrogenations and reductions (cf. John and coworkers, *C. A.* **33**, 1731[1]). Expts. for the detn. of the surface tension and parachors and a polarographic investigation of the potentials involved when these compds. are oxidized are under way. XIV. **Absorption spectra of tocopherols, chromans, coumarans, and related compounds.** T. J. Webb, Lee Irvin Smith, W. A. Bastedo, Jr., Herbert E. Ungnade, W. W. Prichard, Harvey H. Hoehn, S. Wawzonek, J. W. Opie and F. L. Austin. *Ibid.* 389–96.—After a review of the previous work on the ultraviolet absorption spectra of vitamin E compds., the absorption spectra of 15 compds. including the tocopherols, chromans and coumarans are given and the relationship between their structure and the vitamin E activity is discussed. XV. **An extension of the analytical method of Furter and Meyer.** Herbert E. Ungnade and Lee I. Smith. *Ibid.* 397–400.—The colorimetric method of Furter and Meyer (*C. A.* **33**, 4612[9]) for the detn. of tocopherols has been extended to a no. of simpler chromans and coumarans. The results are given in a table and a no. of curves. From these it appears that the method is specific not only for all of the tocopherols but also for 6-hydroxychromans in general. By means of this method it seems possible to distinguish clearly between 6-hydroxychromans and 5-hydroxycoumarans. F. E. Brauns

Chemistry of vitamin E. XVIII. Condensation of phenols and hydroquinones with allylic alcohols, allylic halides and conjugated dienes. Lee Irvin Smith, Herbert F. Ungnade, J. R. Stevens and C. C. Christman. *J. Am. Chem. Soc.* **61**, 2615–18(1939); cf. *C. A.* **33**, 8613[9].—Claisen (German pat. 394,797(1924)) has reported that allylic carbinols, as well as appropriate diols which give dienes when catalytically dehydrated, condense with phenols to give chromans. G. implied that when the carbinols and diols condensed with phenols, the 1st step involved formation of the diene which then condensed with the phenol. Trimethylhydroquinone (I), CH_2:CH-CH_2OH and $ZnCl_2$ in C_6H_6, heated 3.5 hrs. at 200°, give 2,1,6,7-tetramethyl-5-hydroxycoumarone. I and Me-CH(OH)CH:CH_2 (3 hrs. at 200°) give the *2,3,4,6,7-tetra-Me analog* (II), m. 119.5–20.5°; it gives a greenish yellow color with cold concd. H_2SO_4, changing to orange-yellow with $FeCl_3$; it reduces alc. $AgNO_3$ slowly. In order to reach a decision as to whether the diene was an intermediate, I was condensed with EtCH(OH)CH CH_2 (III) and with MeCH CHCH CH_2 (IV); the products should be the same if the diene (IV) is an intermediate. This is not the case. III gives *2,4,6,7-tetramethyl-3-ethyl-5-hydroxycoumaran*, m. 88–9°; it gives a red color with alc. HNO_3 and a bright greenish yellow color with cold concd. H_2SO_4. IV gives *2,5,7,8-tetramethyl-2-isohexyl-6-hydroxychroman(?)*, b_{10-4} 110–15°; it gives a yellow color with concd. H_2SO_4. *m*-Xylohydroquinone (V) and CH_2 $CHCH_2OH$ give an oil, which was not purified, but is considered to be mostly 2,4,6-trimethyl-7-allyl-5-hydroxycoumaran (VI). The synthesis of α-tocopherol from I and phytol by an improved method is also described. I and 1,3-pentadiene with $ZnCl_2$ and H_2SO_4 in AcOH (refluxed 1 hr.) give *2-ethyl-5,7,8-trimethyl-6-hydroxychroman*, m. 115–16°, and giving a yellow color with concd. H_2SO_4. A mechanism is proposed for these condensations which, though not proven, correlates the facts well. CH_2:$CHCH_2Cl$ reacts with I under the same conditions as the bromide and gives the same product. Crotyl chloride gives a mixt. consisting predominantly of II (explained by an isomerization of the halide); it also reacts with I in C_6H_6 ($ZnCl_2$ as catalyst) at atm. pressure and in an inert atm. V and CH_2:$CHCH_2Br$ give VI. XIX. **Alkenylation of phenol with 4-chloro- and 4-bromo-2-hexene; rearrangement of the phenyl ether.** Lee Irvin Smith, Herbert E. Ungnade, Walter M. Lauer and Robert M. Leekley. *Ibid.* 3079–83.—Hurd

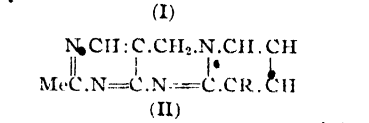
and Cohen (*C. A.* **25**, 2982) obtained PhOCHEtCH: CHMe (I) from PhOH and 4-chloro-2-hexene (II) with K_2CO_3 in Me_2CO. Repetition of the work showed that the product is a mixt. of I with mono- (III) and dialkylphenols (IV). PhOH (183 g.) and 229 g. II give after 8 hrs. 60 g. I, 45 g. III and 48 g. IV; 94 g. PhOH and 111 g. II after 24 hrs. give 47 g. I, 22 g. III and 5 g. IV. III was extd. by aq. alkali and IV by Claisen's alkali. I undergoes rearrangement at a measurable rate at 100° (0.88% in 24 hrs.); at 120° in 24 hrs. 9.6% is rearranged. I b_{10-9} 34.5–5.5°, b_{18} 116–20°, n_D^{20} 1.5059. III b_{10} 135–7°, n_D^{20} 1.5296; IV b_{11} 175–9°, n_D^{20} 1.5224. Refluxing III with C_5H_5N.HCl for 60 min. causes cyclization; the product b_{10} 106–8°, n_D^{20} 1.5225, and is insol. in alkali. Action of O_2 on III and IV showed the products to be mixts. With $BrCH_2CO_2Et$ III yields a mixt. of *o*- and *p*-(*α-ethylcrotyl*)-*phenoxyacetic acids*, m. 110–10.5° and 92.5–6°, resp., sepd. by about 30 crystns. alternately from petr. ether and aq. AcOH. Reduction yields *o*- and *p*-(3-hexyl)phenoxyacetic acids (V and VI), m. 75–6° and 82–3°, the structures of which follow from their syntheses: *o*-$MeOC_6H_4MgBr$ and 3-hexanone give a carbinol which, distd. with H_2SO_4, gives a mixt. of *o-hexenylanisoles*, b_{14} 120.5°; catalytic reduction yields *o-3-hexylanisole*, b_9 104–5°, n_D^{20} 1.4975, d_{20}^{20} 0.9242; refluxing with HI in AcOH-Ac_2O for 2 hrs. gives *o-3-hexylphenol*, b_{10} 109–11°, n_D^{20} 1.5223; $BrCH_2CO_2Et$ gives V. *p-Hexenylanisoles*, b_{15} 125–30°, n_D^{20} 1.5223; *p-3-hexylanisole*, b_{15} 125–5.5°, n_D^{20} 1.4988; *p-3-hexylphenol*, b_{14} 134–45°; with $BrCH_2CO_2Et$ this yields VI. IV (2,6-diallylated phenols) showed vitamin E activity in 50-mg. doses; I, II and the cyclized products from II were inactive. C. J. West

Coloring matters in soybean. I. Isolation of four kinds of isoflavone from soybean. Kozi Okano and Iwao Beppu. *J. Agr. Chem. Soc. Japan* **15**, 645–52, *Bull. Agr. Chem. Soc. Japan* **15**, 110(1939)(in English).—Lecithin was removed from the alc. ext. by the addn. of NaCl, and then a crude saponin was pptd. with acid from the filtrate. The crude saponin was dissolved in alc. and pptd. with Pb acetate. The Pb was removed from the filtrate and a mixt. of EtOH and ether was added to the soln. Yellow needles (IV), m. 265°, were isolated from the insol. part. Colorless needles (I), m. 318°, faintly yellow needles (II), m. 298°, and faintly yellow lustrous needles (III), m. 255°, were obtained from the sol. part. I was insol. in H_2O, C_6H_6 and ether, difficultly sol. in alc., sol. in MeOH. The $FeCl_3$ reaction was yellowish brown. The formula $C_{16}H_{12}O_6$ is given. I is named *latorin*. Di-Ac deriv., colorless needles, m. 185°. Mono-Me ether, yellowish needles, m. 160–3°; di-Me ether, colorless needles, m. 165°. Cresorcinol, HCO_2H and *p*-hydroxyphenylacetic acid were isolated by heating I with 5% KOH for 15 min. 1-Methyl-2-hydroxy-4-methoxybenzene, m. 63°, and 4-methoxyphenylacetic acid, m. 85°, were isolated from the di-Me ether of I by alkali fusion. I may be 8-methyl-5,4′-dihydroxyisoflavone. II was insol. in H_2O, ether and C_6H_6 and sol. in EtOH, MeOH and alkali. The $FeCl_3$ reaction was violet or violet-brown. The formula $C_{16}H_{12}O_6$ is given. II is called *methylgenistein*. Tri-Ac deriv., m. 184°; di-Me ether, m. 125–31°; tri-Me ether, m. 154.5°. Methylphloroglucinol, m. 214°, HCO_2H and *p*-hydroxyphenylacetic acid were isolated from the products of decompn. of II by alkali. 1-Methyl-2-hydroxy-4,6-dimethoxybenzene, m. 60°, and 4-methoxyphenylacetic acid, m. 85°, were isolated from the tri-Me ether of II by alkali fusion. II may be 8-methyl-5,7,4′-trihydroxyisoflavone. III was sol. in alc. The $FeCl_3$ reaction was reddish violet. The formula $C_{22}H_{22}O_{10}$ is given. III is named *methylisogenistin*. It was hydrolyzed to glucose and an aglucone, m. 301–2°. The formula $C_{16}H_{12}O_5$ is given for the aglucone. The $FeCl_3$ reaction was violet-red. Ac deriv., m. 188°; di-Me ether, m. 242°; tri-Me ether, m. 152–3°. Methylphloroglucinol, HCO_2H and *o*-hydroxyphenylacetic acid, m. 144°, were isolated by the decompn. of the aglucone with KOH. The aglucone may be 8-methyl-5,7,2′-trihydroxyisoflavone, an isomer of II. IV was insol. in H_2O, difficultly sol. in hot H_2O. The $FeCl_3$ reaction was red or reddish purple. The formula $C_{21}H_{20}O_{10}$ is given. IV is named *isogenistin*. It was hydrolyzed into glucose and an aglucone, m. 302°. The aglucone is named *isogenistein*. It formed faintly yellowish needles sol. in EtOH and MeOH, and insol. in H_2O. The $FeCl_3$ reaction was violet. The formula $C_{15}H_{10}O_5$ is given. Tri-Ac deriv., colorless needles, m. 189°; di-Me ether, colorless needles, m. 120–5°. Phloroglucinol, HCO_2H and *o*-hydroxyphenylacetic acid were isolated from the decompn. product of isogenistein by KOH fusion. Isogenistein may be 5,7,2′-trihydroxyisoflavone, an isomer of genistein. Y. Kihara



Osage-orange pigments. II. Isolation of a new pigment, pomiferin. M. L. Wolfrom, F. L. Benton, A. S. Gregory, W. W. Hess, J. E. Mahan and P. W. Morgan. *J. Am. Chem. Soc.* **61**, 2832–6(1939); cf. *C. A.* **32**, 3408⁸.—The dried meal of the fruit of the osage-orange tree (*Maclura pomifera* Raf.) was extd. with petr. ether and Et_2O and the Et_2O-sol. material was recrystd. repeatedly from xylene, giving *pomiferin* (I), yellow, $C_{25}H_{24}O_6$, m. 200.5°; the mother liquor gives osajiin (II), $C_{25}H_{24}O_6$, m. 189°. Both I and II give only a yellow color with pyroboroacetate in Ac_2O and with EtOH-Ni$(OAc)_2$. I or II in Et_2O in a CH_4 atm. with 10% NaOH gives an aq. layer with a greenish yellow color of alk. II; CO_2 regenerates the yellow color of II. II gives a *mono-p-toluenesulfonate*, golden yellow, m. 152°; it gives a green color with alc. $FeCl_3$. II (5 g.) in 75 cc. boiling AcOH, treated dropwise with 3 cc. concd. H_2SO_4 or concd. HCl and the soln. allowed to stand overnight, gives 4.66 g. of *isodosajin* (III), m. 285° (decompn.); $FeCl_3$ gives no color; it reduces Fehling soln. and in C_5H_5N Tollens reagent; it is sol. in warm 20% KOH to give a greenish yellow soln. from which acidification ppts. III; H_2SO_4 in AcOH gives a yellow color. I yields a *di-p-toluenesulfonate* (IV), m. 148° (the previously described deriv. of II). I and H_2SO_4 in AcOH give *isopomiferin* (V), m. 265°; $FeCl_3$ gives a green color; V reduces Fehling soln. and Tollens reagent. The isomerism of IV gives the *di-p-toluenesulfonate* (VI) of V, m. 194°; $FeCl_3$ gives no color and the deriv. does not reduce Fehling soln. or Tollens reagent; it is unchanged by boiling with Ac_2O and AcONa for 2 hrs. VI also results from V and *p*-$MeC_6H_4SO_2Cl$ in C_5H_5N. I (1 g.) and 24 cc. Ac_2O in 12 cc. C_5H_5N, kept at 0° overnight, give 1 g. of the *diacetate* (VII), bright yellow, m. 134.5°; alc. $FeCl_3$ gives a green color; hydrolysis with NaOH at 0° gives I. Refluxing 1 g. I with 75 cc. Ac_2O and 6 g. AcONa for 3 hrs. gives 1.2 g. of I *triacetate*, m. 154°, which gives no color with alc. $FeCl_3$; this also results from VII. II, similarly treated, gives the previously described diacetate, m. 164°. I and Me_2SO_4 in MeOH-KOH at 0° give I *di-Me ether*, m. 132°; $FeCl_3$ gives a green color; AcOH-H_2SO_4 gives an orange color; refluxing with Ac_2O and AcONa for 3 hrs. gives the *di-Me acetate*, m. 128–9°. Methylation of I in boiling Me_2CO with Me_2SO_4-KOH gives the *tri-Me ether*, m. 139.5°. Absorption spectra are given for I, II, III and V; a single band spectrum was obtained for each compd. C. J. West

Pyridine series. I. An improved synthesis of 2,3 dimethylpyridine and the conversion of the latter into an analog of thiamine. J. Finkelstein and R. C. Elderfield. *J. Org. Chem.* **4**, 365–75(1939).—According to Erlenmeyer, Berger and Leo (*C. A.* **27**, 4842) a bivalent S atom contains a shell of orbit electrons similar to that of the "pseudo-atom" $-CH{:}CH-$ and this may explain the similarity of the phys. and chem. properties between members of the C_6H_6 and the thiophene series. When E.'s theory of isosterism is applied to vitamin B_1 or thiamine, the thiazole ring changes into a pyridine ring and a study of the physiol. properties of such a substance should be of interest. Its synthesis requires a method for the prepn. of 2,3-disubstituted pyridines. *2,3-Dimethylpyridine* (I) is synthesized and, by making use of the activity of the H atom in the Me in the 2-position, I is condensed with HCHO to *2-(2-hydroxyethyl)-3-picoline* which in turn is condensed with pyrimidine. Since the methods hitherto reported for the prepn. of I are unsatisfactory a new method has been developed. $BrCH_2CH_2CH_2OEt$ (400 g.) is condensed with Et sodio-*α*-methyl-



acetoacetate from 300 g. ester and 57.5 g. Na in dioxane soln. After the mixt. has been heated for 60 hrs. and the NaBr removed by centrifuging, the dioxane is distd. off and the residue fractionated *in vacuo*. The fraction b_{16} 111–3° is *Et α-methyl-α-(γ-ethoxypropyl)acetoacetate* (II). The yield is 200 g. The residue of this distn. gives 32 g. of a product, $b_{0.5}$ 128–30°, which is not further investigated. When this condensation is carried out in abs. EtOH soln., *Et α-methyl-δ-ethoxyvalerate* (III), b_{18} 96–7°, n_D^{25} 1.4168, is obtained (cf. Dieckmann, *Ann.* **317**, 27(1901); Vavon and Horeau, *C. A.* **30**, 2025). Sapon. of III gives *α-methyl-δ-ethoxyvaleric acid*, b_{11} 137–9°, n_D^{25} 1.4289. Hydrolysis of 33 g. II with 6.8 g. NaOH in 33 g. H_2O in a bomb under 1000 lb. H pressure at 250° for 8 hrs (cf Adkins and Connor, *C. A.* **26**, 4796) gives *3-methyl-6-ethoxyhexan-2-one* (IV), b_{17} 96–9°, in 75% yield. In addn. 5 g. of a product, b_{17} 111–3°, is obtained. When a soln. of 11 g. IV in 80 cc. AcOH is satd. at 0° with HBr, then heated for 2 hrs. on a steam bath and the mixt. poured after cooling on 300 cc. cracked ice, 6 g. *3-methyl-6-bromohexan-2-one* (V) is extd. with $CHCl_3$ and $b_{0.5}$ 70–4°. When 20 g. V is allowed to stand at room temp. in 200 cc. 10% abs. alc. NH_3 for 18 hrs. and the mixt. is then neutralized with HCl, salts crystallize on cooling and are then filtered off. The filtrate is concd. under reduced pressure and dissolved together with the salts in a sufficient amt. of H_2O. The soln. is made alk. and steam distd. The distillate is satd. with KOH and extd. with Et_2O, the Et_2O soln. is dried and the *2,3-dimethyltetrahydropyridine* (VI) is distd. and b. 151–7°. The yield is 7.5 g. In agreement with Sachs (*Ber.* **32**, 62(1899)) and Lipp and Wimmann (*C. A.* **9**, 1759) its picrate m. 151–5°. Dehydrogenation of VI by Zn distn. gives poor yields of I. The application of the dehydration method of Orekhov and Menshikov (*C. A.* **25**, 3847) by heating 2-picoline (VII) with AcOAg results in a demethylation. Hydrogenation of pyridine with palladized asbestos at 150° leads to piperidine but at 250° this reaction is reversed. When aldehydocollidine is shaken in AcOH with Adams and Shriner's catalyst under 3 atm. H, *2-methyl-5-ethylpiperidine* (VIII), b. 160°, is obtained. Its chloroplatinate m. 145–7°. When VIII is slowly passed over palladized asbestos at 275°, *aldehydocollidine*, b. 177–8°, is obtained in excellent yield. Its picrate m. 164–5°. VI, when passed over Pd asbestos in the same way gives I, b. 162–4°, in 90% yield. Its picrate m. 187–8°. The condensation of I with HCHO according to Koenigs and Bernhart (*Ber.* **38**, 3049(1905)), or Oparina (*C. A.* **25**, 3651) offers difficulties, but the substitution of the reactive H in the Me group in the 2-position by Li is achieved by interaction of 12 g. VII with $PhLi$ prepd. from 20.7 g. PhBr. Addn. of 6.5 g. freshly prepd. HCHO with stirring for 45 min. at room temp., followed by refluxing for 45 min. and decompg. with HCl and ice, gives 8 g. *2-(2-hydroxyethyl)pyridine* (IX) which is extd. with $CHCl_3$ and distd. at 2 mm. It b. 88–90°; chloroplatinate, m. 176° (decompn.). Oxidation of IX with $KMnO_4$ yields *picolinic acid*, m. 216°. When the same method as for IX is applied to I, *2-(2-hydroxyethyl)-3-picoline* (X), b_1 94–5°, is obtained; picrate, m. 137–8°. When to a suspension of 100 mg. *2-methyl-4-amino-5-bromoethylpyrimidine-HBr* (XI) in 10 cc. light petrolatum, heated on a water bath, a 10% excess of IX is added with const. stirring and the mixt. is heated for 1 hr., *2-[(4-amino-2-methyl-5-pyrimidyl)methyl]-2-(2-hydroxyethyl)pyridinium bromide-HBr* (XII) crystallizes. It is purified by pptn. from its EtOH soln. with Et_2O. It m. 240–5° (decompn.). It also decomps. on drying at 100° at 10 mm. Condensation of XI with X instead of IX gives *1-[(4-amino-2-methyl-5-pyrimidyl)methyl]-2-(2-hydroxyethyl)-3-picolinium bromide-HBr* (XIII), m. 240–2° (decompn.). XII and XIII do not show antipolyneuritic activity but approximate the activity of thiamine as measured by CO_2 evolution in the yeast test. F. E. Brauns

Formation of β-hydroxypyridine derivatives from hexoses and ammonium salts. I. Kiyosi Aso. *J. Agr. Chem. Soc. Japan* **15**, 629–33; *Bull. Agr. Chem. Soc. Japan* **15**, 107–8(1939) (in English).—Glucose or sucrose aq. solns were heated with $(NH_4)_2SO_4$, NH_4Cl or NH_4 oxalate at 155–65° for 1–3 hrs. The product was extd. with ether. The ether ext. contained levulinic acid. Three bases were isolated from the ether-insol. part. The base m. 166–7° was identified as 2-methyl-5-hydroxypyridine. The base m. 201–2° and the base m. 124–5° may be, resp., 2- or 3-methyl-5,6-dihydroxypyridine and 2-hydroxymethyl-5-hydroxypyridine. Y. Kihara

Synthesis of a pyridine derivative of biological interest. Siro Morii. *J. Oriental Med.* **30**, English abstr. 169–70 (1939). By condensing nicotinamide with 2-methyl-6-amino-5-bromomethylpyrimidine-HBr, (I) (R = $CONH_2$) is obtained, which goes to II when oxidized by alk. $K_3Fe(CN)_6$. The product is a blue fluorescent dye

Utilization of alkoxy ketones in the synthesis of quinolines by the Pfitzinger reaction. Loy B. Cross and Henry R. Henze. *J. Am. Chem. Soc.* **61**, 2730–3(1939); cf. *C. A.* **33**, 6315². Isatin (I) (46 g.) and 32 g. $EtOCH_2Ac$ with 200 g. 33% KOH, heated 24 hrs. on a steam bath, give 44% of *3-ethoxy-4-quinaldinecarboxylic acid* (II), m. 243° (decompn.) (all m. ps. cor.). I and $EtOCH_2COEt$ give 92% of *2-ethyl-3-ethoxycinchoninic acid* (III), m. 199–201° (decompn.). 5-Methylisatin and $EtOCH_2COEt$ give 33% of the *6-Me deriv.* of III, m. 222° (decompn.). Heating II at 250° gives 59% of 3-ethoxyquinaldine (IV), m. 68–9°; III gives 47% of *2-ethyl-3-ethoxyquinoline* (V), b_{7-8} 138–40°, m. 58.5°. II (2 g.) and concd. HCl, heated 2 hrs. at 150°, give 1.25 g. of *3-hydroxy-4-quinaldinecarboxylic acid*, m. 242.4° (decompn.). Heating IV and concd. HCl at 180° for 3 hrs. gives 81.5% of 3-hydroxyquinaldine (VI), m. 260°; V gives 93% of *2-ethyl-3-hydroxyquinoline* (VII), m. 206–8° (decompn.). IV, HI and red P, refluxed for 7 days at 150°, give a mixt. of VI and quinaldine; 6.6 g. of V gives 3 g. of the *HI salt* (VIII) of V, m. 193–8° and 1 g. of VII. III, HI and red P, heated at 125° for 24 hrs., give *2-ethyl-3-hydroxycinchoninic acid* (IX), yellow, m. 208.9° (decompn.); in a 2nd expt. the mixt. was refluxed at 140–50° for 18 hrs.; the chief product was IX, with a small amt. of VIII. Reduction of VII by heating it with concd. HCl for 5 hrs. at 175°, adding addnl. concd. HCl and treating with Sn, gives 21% of 2-ethyl-1,2,3,4-tetrahydroquinoline, b_7 125–7°, n_D^{25} 1.5652, d_4^{20} 1.0178; *picrate*, bright yellow, m. 143–5°. VI and $C_6H_4(CO)_2O$, heated 3 hrs. at 200°, give the phthalone, $C_{18}H_{11}NO_3$, dark orange, m. 264.6°; this also results from II in 31% yield. C. J. West

Synthesis of certain substituted quinolines and 5,6-benzoquinolines. R. Gordon Gould, Jr., and Walter A. Jacobs. *J. Am. Chem. Soc.* **61**, 2890–5(1939).—A convenient method of synthesis of certain 4-hydroxyquinoline and 4-hydroxy-5,6-benzoquinoline derivs. has been found in the condensation of $PhNH_2$ and β-$C_{10}H_7NH_2$ derivs. with $AcCH(CO_2Et)_2$ (I) or ethoxymethylenemalonic ester (II) followed by cyclization at 250°. 3,1-$H_2NC_{10}H_6CO_2H$ and $AcCH_2CO_2Et$ in MeOH give a quant. yield of *Et (3-naphthyl-1-carboxylic acid)-β-aminocrotonate*, m. 157–8°; cyclization in 10–30 parts of mineral oil at 250–65° in an atm. of dry N gives a nearly quant. yield of *4-hydroxy-5,6-benzoquinaldine-7-carboxylic acid* (III), which does not m. 360°; *HCl salt*; *Me ester*, m. 295–6° (decompn.); *Et ester*, m. 295–7°. 3-Amifonaphthostyril (IV) (2.5 g.) and $AcCHCO_2Et$ give 3.2 g. of *Et N-(3-naphthostyryl)-β-aminocrotonate*, m. 180–2°; cyclization gives *4-hydroxy-3'-amino-5,6-benzoquinaldine-7-carboxylic lactam*, does not m. at 360°; *HCl salt*. $PhNH_2$ and I give 30% of the *Et ester*, m. 104–7°, of 4-hydroxyquinaldine-3-carboxylic acid, m. 247–8°. IV and I, several months at

room temp., give *α-carbethoxyacetoacetyl-3-aminonaphthostyril*, m. 268–70° (decompn.). Anilidomethylenemalonic ester on cyclization in mineral oil gives 60% of 4-hydroxyquinoline-3-carboxylic acid, m. 267–8°. 3,1-$H_2NC_{10}H_6CO_2Me$ and II, heated 15 min. at 100°, give *Et N-(3-naphthyl-1-carbomethoxy)-β-amino-α-carbethoxyacrylate*, m. 89–90°; cyclization at 250° gives *4-hydroxy-5,6-benzoquinoline-3,7-dicarboxylic acid*, does not m. 360°. IV and II give 75% of *Et N-(3-naphthostyryl)-β-amino-α-carbethoxyacrylate*, light yellow, m. 231–2°; cyclization gives a nearly quant. yield of *4-hydroxy-3'-amino-5,6-benzoquinoline-3,7-dicarboxylic lactam*, does not m. 360°; it is sol. in dil. $NaHCO_3$ and from concd. solns. forms a sparingly sol. Na salt; refluxing with Zn-Hg in AcOH for 5 hrs. gives the *2,3-dihydro deriv.*, does not m. 350°. I (11 g.), 60 cc. 50% KOH, 5 cc. CCl_4, a little EtOH and 1 g. Cu, refluxed for 24 hrs. and the product extd. with 1% HCl, give 3 g. of *4-hydroxy-5,6-benzoquinaldine-3,7-dicarboxylic acid* (V), does not m. 360°; *mono-Me ester*, from MeOH and HCl, m. 290–5° (decompn.); *di-Me ester* (VI), from MeOH and H_2SO_4, m. 239–40° (decompn.); CH_2N_2 gives the *4-MeO deriv.* of VI, m. 142–4°. V yields a mixt. of isomeric NO_2 derivs., which is reduced by $Fe(OH)_2$ to about 30% of *3'-amino-4-hydroxy-5,6-benzoquinaldine-3,7-dicarboxylic lactam*, orange-yellow, which does not m. 360°, and about 70% of an *NH_2 deriv.* of V, which does not m. 360°; these were sepd. by extn. with half-satd. $NaHCO_3$. 3,1-$H_2NC_{10}H_6CO_2Me$, $AcCO_2H$ and AcOH in EtOH, refluxed 4–5 hrs., give the *7-Me ester* (VII), m. 265–6° (decompn.), of *5,6-benzoquinaldine-4,7-dicarboxylic acid*, m. 298–9° (decompn.); oxidation of VII with SeO_2 in C_5H_5N gives the *7-Me ester*, m. 199–200° (decompn.), of *5,6-benzoquinoline-2,4,7-tricarboxylic acid*, m. 285–6° (decompn.). II, AcH and $AcCO_2H$ in EtOH, refluxed 4 hrs., give a poor yield of *3'-amino-5,6-benzoquinaldine-4,7-dicarboxylic lactam*, m. 340 2° (decompn.). 2-$C_{10}H_7NH_2$ and epichlorohydrin give *3-hydroxy-1,2,3,4-tetrahydro-5,6-benzoquinoline*, m. 82 3°; *HCl salt*. II yielded an anomalous product. HCHO in the above expts. gave only complex bimol. products. C. J. West

Synthesis in the 1,2,3,4 - tetrahydroquinoline series. Wm. S. Emerson and J. W. Davis. *J. Am. Chem. Soc.* **61**, 2830–2(1939). 2,8-Dimethylquinoline (I), b. 215–55°, n_D^{25} 1.5955, d_4^{20} 1.036, gives a *zinc chloride-HCl double salt*, $2I.2HCl.ZnCl_2$, m. 270° (decompn.). Reduction of 39 g. I in 100 cc. H_2O and 200 cc. concd. HCl with excess of Sn (refluxing 19 hrs.) gives 69% of *2,8-dimethyl-1,2,3,4-tetrahydroquinoline* (II), b. 250–5°, d_4^{20} 1.000, n_D^{25} 1.5610; *picrate*, yellow, m. 159.5–61°; *$ZnCl_2$-HCl salt*, m. 270° (decompn.); *Bz deriv.*, m. 118.5–20°. II and MeI on standing 16 hrs. give 70% of the *HI salt*, m. 154.5–5.5°, of *1,2,8 trimethyl-1,2,3,4-tetrahydroquinoline*, b_{21} 130°, n_D^{25} 1.5450, d_4^{20} 0.9826; *picrate*, m. 177–8°; *$ZnCl_2$-HCl salt*, m. 213–14°. 2,6-Dimethylquinoline (III) gives a *$ZnCl_2$-HCl salt*, m. 211.5–13°; reduction gives 70% of crude *2,6-dimethyl-1,2,3,4-tetrahydroquinoline* (IV), b_{25} 142–9°; the crude product (6 g.) in 10 cc. concd. HCl and 30 cc. H_2O, treated with 3 g. $NaNO_2$, the oil extd. with Et_2O and the residue added with cooling to 15 g. $SnCl_2$ and 75 cc. concd. HCl, gives 2.5 g. III, b_{21} 147–9°; the picrate when first prepd. m. 126–8°; 2 crystns. from EtOH raised the m. p. to 165–9°; the mother liquor contains the picrate of III. The Bz deriv. of IV m. 104–5°; the $ZnCl_2$-HCl salt m. 187–95°. IV reacts vigorously with MeI, giving the *HI salt*, m. 187–8.5°, of *1,2,6-trimethyl-1,2,3,4-tetrahydroquinoline*, b_{20} 145°, n_D^{25} 1.5611, d_4^{20} 0.9906, which is obtained in 64% yield by refluxing 1,2,6-trimethyl-1,2,3,4-tetrahydroquinoline-HI with excess Sn and HCl for 7 hrs.; *picrate*, yellow, m. 141–2°. IV is much more unstable and reactive than II; however, its *N*-Me deriv. is stable. C. J. W.

Nitrogen compounds in petroleum distillates. XV. Countercurrent acid extraction of kero bases. Isolation of 2,4-dimethyl-8-propylquinoline. W. Nelson Axe and J. R. Bailey. *J. Am. Chem. Soc.* **61**, 2609–12(1939); cf. *C. A.* **33**, 5402[1].—Details are given of the method and app. for countercurrent extn. of petr. bases. The 292–3° fraction was sepd. into 7 fractions, the component fractions being transformed into the picrates in Me_2CO and sepd. into Me_2CO-sol. and -insol. fractions; the latter were recrystd. from glacial AcOH and the former from EtOH; the free bases were liberated and transformed into the $ZnCl_2$ salts. The Me_2CO-insol. picrates yielded in several fractions 2,3-dimethyl-8-ethylquinoline and the 8-Pr analog and the $ZnCl_2$ salts yielded *2,4-dimethyl-8-propylquinoline* (I). Yields are given for the 292–3°, the 303° and the 280–3° fractions. The 303° fraction gives 4.7% of I by the countercurrent extn. and 1.8% by the fractional degassing method. I b_{747} 298°, d_4^{20} 0.9992, n_D^{20} 1.5748; *$ZnCl_2$ salt*, m. 225–6°; heating with $C_6H_4(CO)_2O$ for 4 hrs. gives the orange-yellow *phthalone*, $C_{22}H_{19}O_2N$, m. 198–9°. Oxidation of I with CrO_3 yields 2,4-dimethylquinoline-8-carboxylic acid. I was synthesized from Ac_2CH_2 and *o*-$PrC_6H_4NH_2$. **XVI. Use of multiple acid extraction in isolation of 2,3,4-trimethyl-8-ethylquinoline.** Richard A. Glenn and J. R. Bailey. *Ibid.* 2612–13.—The fraction b. 305–15° was sepd. into 10 fractions by multiple acid extn. and into 95 fractions by fractional distn. Fractions b. 314–19°, with d_4^{20} from 1.0174 to 1.0386 and n_D^{25} 1.5841 to 1.5920, were transformed into the picrates and crystd. from 60% AcOH, giving the *picrate*, lemon, m. 216°, of *2,3,4-trimethyl-8-ethylquinoline*, (I), b. 320°, m. 52.3–3°, n_D^{25} 1.5798; MeOH is a selective solvent for recrystn. of this compd. Oxidation gives 2,3,4-trimethylquinoline-8-carboxylic acid. I and $C_6H_4(CO)_2O$, heated 4 hrs. at 190°, give the *phthalone*, $C_{23}H_{19}O_2N$, yellow, m. 253°. I yields a *nitrate*, m. 159.5–60° (decompn.); an *acid sulfate*, m. 245–6°; and a *HCl salt*, m. 203–4°. I can be synthesized from Ac_2CHMe and *o*-$EtC_6H_4NH_2$. **XVII. The use of multiple acid extraction in isolation of 2,3,4-trimethyl-8-propylquinoline.** Leslie M. Schenck and J. R. Bailey. *Ibid.* 2613–15.—Multiple acid extn. of the kero bases yields an aromatic base with n_D^{25} 1.5841; further processing yields fractions b. 323 and 326° with n_D^{25} 1.5807, which with HNO_3 in 1:10 Me_2CO-Et_2O yield the *nitrate*, m. 160.1° (decompn.), of *2,3,4-trimethyl-8-propylquinoline*, b. 330°, m. 69–70°, n_D^{25} 1.5618, n_D^{25} 1.5731; *picrate*, lemon, m. 211–11.5°; *acid sulfate*, m. 230.5–1°; *HCl salt*, m. 221–2°. Oxidation yields 2,3,4-trimethylquinoline-8-carboxylic acid. The base was synthesized from Ac_2CHMe and *o*-$PrC_6H_4NH_2$. C. J. West

Azeotropic mixtures of dioxane and its preparation. A. DeMol. *Ing. Chim.* **22**, 262–73(1938).—In order to investigate a new prepn. of dioxane it is important to study the azeotropic mixts. which can produce dioxane. Mixts. of dioxane with the following were studied: H_2O, H_2O and glycol, glycol, EtOH, cyclohexanol, cyclohexanone, acetone, cyclohexane, toluene, benzene, CS_2. The lab. prepn. and phys. and chem. properties of dioxane are discussed. Prepn. of dioxane by direct distn. is not feasible. The usual distn. method was used except that instead of treating the liquid with $CaCl_2$ it was placed directly in the rectifying app. mixed with the calcd. amt. of CS_2. About 85% of the dioxane was recovered.
Ann Nicholson Hird

Monoalkyldioxanes. R. K. Summerbell and R. R. Umhoefer. *J. Am. Chem. Soc.* **61**, 3016–19(1939).—Chlorodioxane (I) is best prepd. (68.5% yield) by passing dry HCl into dioxene at 0°; Et_2O or C_6H_6 as a solvent decreases the yield. Dropwise addn. of I to a Grignard reagent in Et_2O gives monoalkyldioxanes (II), purified by distn. over Na: *Me* (II), $b_{746.5}$ 109–10°, d_4^{20} 0.977, n_D^{20} 1.4188; *Et* (IV), b_{760} 132.5–3°, d_4^{20} 0.955, n_D^{20} 1.4263; *Pr* (V), b_{746} 155.6–7.1°, d_4^{20} 0.943, n_D^{20} 1.4298; *Bu* (VI), b_{735} 178–9°, d_4^{20} 0.932, n_D^{20} 1.4436; *allyl*, $b_{747.6}$ 156–8°, d_4^{20} 0.937, n_D^{20} 1.4442, 72.5% yield. $(CH_2OH)_2$ is formed in the reaction between II and Na. If $ZnCl_2$ is used with BuMgBr the yield of VI is 11%; a by-product in this reaction is a compd., m. 101–2°, which may be *2-butyl-3-dioxanyldioxane*, $O.CH_2.CH_2.O.CH_2.CHCH.CHBu.O.CH_2.CH_2.O$; the reaction of I and EtMgBr gives the *Et analog*, m. 97.5°. III is infinitely sol. in H_2O, IV is sol. to a considerable extent and V and VI are not appreciably sol. The II have a slightly displeasing ethereal odor, which increases

in the higher members. II do not form addn. compds. with picric acid or hydroquinone. The relation of *n* and d appears to be uncommon, in that the slope of the plot of *n vs.* d. is neg. $MeCHClOCH_2CH_2Cl$ treated with 1 mole Br at 0° during 2.5 hrs. gives 73% of *β-chloroethyl α,β-dibromoethyl ether* (VII), b_{12} 108°, fumes in the air and turns yellow in a short time. VII, added to EtMgBr in Et_2O at 0°, gives 25% of *β-chloroethyl α-ethyl-β-bromoethyl ether* (VIII), b_{12} 92–3°, d_4^{20} 1.388, n_D^{20} 1.4770. Refluxing 30 g. VIII with 30 g. KOH in 270 cc. H_2O for 26 hrs. and then at 200–5° for 3.5 hrs. gives 17% of IV. 2,3-Dichlorodioxane (IX) and Mg + MgI_2 in dry Et_2O give 49% of dioxene (X). The yield of X varies with the ratio of I to IX as follows: 1.20 31%; 1·10 44%; 1.5 49%. C. J. West

Dioxadiene. R. K. Summerbell and R. R. Umhoefer. *J. Am. Chem. Soc.* **61**, 3020–2 (1939).—The reaction product of 23 g. Mg turnings and 80 g. I in 500 cc. Bu_2O was heated to 140° and 35.5 g. of 2,3,5,6-tetrachlorodioxane (I) added in 1-2-g lots; the reaction was vigorous and was accompanied by distn. of the *dioxadiene* (II) and the Bu_2O; after 100 cc. distillate had collected 100 cc. Bu_2O was added and after the I had reacted the temp was raised to 155°; distn. of the 300-cc. distillate gave 64% of II, b_{746} 75°, d_4^{20} 1.115, n_D^{20} 1.4350. II is insol. in H_2O. It polymerizes in 2–3 weeks to a hard colorless solid which does not m. 250°; its mol. wt. was not detd. because of its insoly. in H_2O and org. solvents; it reacts slightly with Br. In CCl_4 II reacts with 2 atoms Br, giving 87% of the *di-Br deriv.*, $C_4H_4O_2Br_2$, m. 58°, which decomps. over a period of several weeks when exposed to the atm. II and Cl in CCl_4 give I. II and HCl in CCl_4 give 2,5-dichlorodioxane. II and $HgCl_2$ give a *compd.* $C_4H_2O_2Hg_2Cl_2$(?), with an indefinite m. p. II did not result from the treatment of diglycolic acid anhydride and glycolide with Zn and the pyrolysis of the acetate of dimeric glycolaldehyde. C. J. West

Derivatives of aminomethanethiol. Arthur Binz and Leland H. Pence. *J. Am. Chem. Soc.* **61**, 3134–9 (1939).—Shaking 10 g. piperidine and 20 cc. of 37% aq. HCHO with 10 g. K_2CO_3, filtering off the 1-piperidinomethanol and treating it with H_2S for 3.3 hrs. (temp. rise to 68°) gives 88% of *1-piperidinomethanethiol* (I), $CH_2(CH_2CH_2)_2NCH_2SH$, m. 12.5–15°; *HCl salt* (II), m. 195–205°. On heating I at 150–70° and 4 mm., there results $(C_5H_{10}N)_2CH_2$ and a brittle brownish mass, m. 228 31°, with 58.4% S. Refluxing I with dil. HCl give trithioformaldehyde (III). I and $HgCl_2$ in EtOH give 97% of $O(CH_2S)_2Hg$ (IV), decomps. 95–105°; $Cu(OAc)_2$ gives 91% of *capric methylenedimercaptide* (V), $CH_2(S)_2Cu$, decomps. 105–10°. Treating I with H_2S at 0° for 1.5 hrs. gives *1,3-di(1'-piperidino)-2-thiapropane* (VI), m. 48.5–50.5°; *di-HCl salt* (VII), m. 171–5° (decompn.). Morpholine (VIII) (17.5 g.) with 18 cc. 37% aq. HCHO and 17 cc. concd. HCl, treated with H_2S at 55° for 2 hrs., gives 5.3 g. of *4-morpholinomethanethiol* (IX), $O(CH_2CH_2)_2NCH_2SH$, m. 86–8°; refluxing IX with concd. HCl gives 94% of III; IX and $HgCl_2$ give 94% of IV and $Cu(OAc)_2$ gives V. A by-product in the prepn. of IX, which is obtained in 7.6-g. yield from 8.75 g. VIII and HCHO in C_6H_6 with H_2S with cooling, is probably *1,7-di(4'-morpholino)-2,4,6-trithiaheptane* (X), $[O(CH_2CH_2)_2NCH_2SCH_2]_2S$, m. 77–84°. Reaction of $O(CH_2CH_2)_2NCH_2OH$ with H_2S at 0° gives *1,3-di(4'-morpholino)-2-thiapropane* (XI), m. 107–8°; a by-product is probably *3-(4'-morpholino)-2-thiapropanethiol* (XII), $O(CH_2CH_2)_2NCH_2SCH_2SH$, m. 72–82°, which is also obtained by dissolving XI in H_2O at room temp. Adding $(HOCH_2CH_2)_2NH$ to 37% aq. HCHO with cooling and treating with H_2S for 0.5 hr. gives the *compd.* $(HOCH_2CH_2)_2NCH_2S]_2H$ (XIII), m. 224–6°; it is sol. in 20 parts boiling $(HOCH_2CH_2)_2NH$ and is not pptd. by H_2O. H_2S, passed into a suspension of 18 cc. 37% HCHO and 3 g. $(HOCH_2CH_2)_2NH$ in 175 cc. H_2O at 65°, gives 7 g. of a compd. with a N:S ratio of 1:14.4 which does not m. 230–3°. I and VI in 0.04% aq. soln. killed paramecia immediately and daphnia in 20 min.; lethal doses of IX, XI, XIII, II and VII are 0.025, 0.021, 0.165, 0.05 and 0.083 mg. per g. of body wt. when injected intravenously into mice. C. J. West

Derivatives of piperazine. XVIII. Synthesis of substituted piperazines and the hydrolysis of amines. J. P. Bain and C. B. Pollard. *J. Am. Chem. Soc.* **61**, 2704–5 (1939); cf. *C. A.* **33**, 2138⁶.—This is a continuation of the work of B. and P. (*loc. cit.*) who showed that piperazines may be prepd. from amino alcs. by catalytic alkylation. Cyclohexylamine (I) and $(C_2H_4)_2O$ give *N*-cyclohexylethanolamine (II), b. 118°, n_D^{25} 1.4832, and *N*-cyclohexyldiethanolamine (III), b. 178°, n_D^{25} 1.4927. Heating 1 mole $PhNH_2$ and 2 moles of propylene oxide in 300 cc. dioxane for several hrs. gives *N-phenyldiisopropanolamine* (IV), straw-colored liquid, b_{10} 184–5°; *N-p-tolyl analog* (V) of IV, pink, m. 112°. One mole each of I and II or III in 600 ml. of dioxane with 25 g. Cr-Cu oxide catalyst, heated to 250–70° and shaken 3-4 hrs. in H at 34 atm. pressure, give 20 g. cyclohexanol (VI), 19 g. of a fraction, b_{10} 109–10° and 20% of *1,4-dicyclohexylpiperazine*, m. 118°. I and IV give 20% of *1-cyclohexyl-2,6-dimethyl-4-phenylpiperazine*, b_2 205–10°; I and V give 15% of the *4-p-tolyl analog*, b_5 175–230°. The above were analyzed as the *di-HBr salts*. Heating 60 g. of I, 300 ml. dioxane, 20 ml. H_2O and 20 g. Cu-Cr oxide for 4 hrs. at 260–70° under 34 atm. pressure gives 26% of VI. Diethylcyclohexylamine yields 33% of VI on heating 78 g. in 300 ml. 50% aq. dioxane and 23 g. catalyst at 270–80° without H pressure; there also results a mixt. of mono- and diethylcyclohexylamines. C. J. West

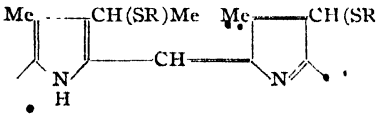
Heteropolar compounds. V. The variation of the dielectric constant of solutions of 2-thio-3-phenyl-4-ethoxy-1,2,3,4-tetrahydroquinazoline with temperature. Alex. Cişman and C. V. Gheorghiu. *Ann. sci. univ. Jassy*, Pt. I, **25**, 424–32 (1939) (in French); cf. *C. A.* **32**, 2943¹.—Measurements were made in PhBr, α-$C_{10}H_7Br$, and MeCOPh solns.; the dielec. const., measured by the movement of the armature of a cylindrical condenser, is less than that of the pure solvent. The curves are almost parallel, the const. of the solns. decreasing less as the temp. rises and the reversible coloration appears. This is in accord with the hypothesis made previously of a reversible heteropolar decyclization between N-3 and C-4 to accompany the appearance of color. On heating above 60° 70°, the color produced is not discharged on cooling and the variation of the dielec. const. with temp. is exactly parallel to that in the pure solvent. This may be due to a change in the quinazoline structure with no decyclization; in MeCOPh soln. the quinazoline reacts with the solvent to yield *2-thio-3-phenyl-4-phenacyl-1,2,3,4-tetrahydroquinazoline*, m. 237°, which shows no reversible coloration and cannot undergo decyclization as suggested. This is also true for 2-thio-3-phenyl-4-oxo-1,2,3,4-tetrahydroquinazoline for which the dielec. const. curves in PhBr are parallel P. M. Apfelbaum

Erythrina alkaloids. VI. Constitution of erythramine. Karl Folkers and Frank Koniuszy. *J. Am. Chem. Soc.* **61**, 3053–5 (1939); cf. *C. A.* **33**, 5405⁵.—Erythramine (I), $C_{18}H_{21}NO_3$, contains a MeO and a CH_2O_2 group; thus all 3 O atoms exist in ether linkages; this is confirmed by the lack of reaction of I with Ac_2O or BzCl. The free I cannot be stored because of progressive decompn.; I is not decompd. by boiling in approx. 5% NaOH in H_2O contg. a little EtOH for 2 hrs.; the hydrohalide salts are stable either dry or in soln. In prepg. derivs. it is essential that the HI salt m. 245° (slow bath) and have $[\alpha]_D$ 220 1°. I forms a *methiodide* (II), yellowish white, m. 96–8°, $[\alpha]_D^{25}$ 176° (H_2O, *c* 0.355). I.HI could not be reduced by the Adams catalyst at room temp.; I in 50 ml. H_2O and 2 ml. concd. HCl is reduced at 2 atm. H pressure in 1 hr., giving the *dihydro deriv.* (III), m. 89–90°, isolated as the *HI salt*, m. 214 15° (decompn.), optically inactive; the *HBr salt*, with 1 mole H_2O, m. 240°; the *methiodide*, with 0.5 mole H_2O, m. 160–1°; these derivs. could not be dehydrated without decompn. The N atom of I is tertiary and is probably common to 2 nuclei of the mole. The unsatn. consists of 1 benzenoid nucleus

and 1 ethylenic double bond. The mole appears to contain 4 6-membered nuclei exclusive of the CH_2O_2 bridge. II is about 1/5 as active and III about 1/30 as active as natural I for curare-like action in frogs. C. J. West

Structure of monocrotaline, the alkaloid in Crotalaria spectabilis and Crotalaria retusa. I. Roger Adams and E. F. Rogers. *J. Am. Chem. Soc.* **61**, 2815–19(1939).—Two kg. of *Crotalaria spectabilis* seed are extd. with 95% EtOH for 72 hrs., the green-black soln. acidified with citric acid (Congo paper), the solvent removed *in vacuo* and the residue taken up in 400 cc. H_2O; the fat is extd. with Et_2O and $CHCl_3$; the aq. soln. is then treated with 200 cc. $CHCl_3$ and satd. aq. Na_2CO_3 until the soln. is alk. to litmus and the monocrotaline (I), $C_{16}H_{23}O_6N$, is extd. with $CHCl_3$ and purified by crystn. from abs. EtOH; the yield of I is 65 g. (3.2%); Neal, Rusoff and Ahmann, *C. A.* **30**, 1182[8], give the formula $C_{16}H_{26}O_6N$. I m. 197–8° (decompn.) (all m. ps. cor.), $[\alpha]_D^{25}$ −54.7°, (0.5054 g. in 10 cc. $CHCl_3$); I does not react with HNO_2; MeN and MeO groups are absent. No evidence is obtained of the presence of any other alkaloid. *Crotalaria retusa* gives 1.89% of I. *HCl salt* of I, m. 184° (decompn.), $[\alpha]_D^{25}$ −38.4° (1.3 g. in 25 cc. H_2O); *methiodide*, with 3 moles MeOH, m. 205° (decompn.), $[\alpha]_D^{25}$ 23.4° (0.31 g. in 10 cc. MeOH). Refluxing 20 g. of I and 40 g. $Ba(OH)_2.8H_2O$ in 250 cc. H_2O for 1 hr. gives 4.2 g. (48%) of *monocrotic acid* (II), $C_7H_{12}O_3$, b_{18} 145–6°, $n_D^{17.5}$ 1.4449, d_4^{26} 1.072; *p-bromophenacyl ester*, m. 78°. The aq. soln. after extn. of II by Et_2O is evapd. to dryness, the sirup dissolved in 100 cc. abs. EtOH and the residue from the ext. with EtOH gives 87% of the *HCl salt*, m. 161 2°, $[\alpha]_D^{25}$ −15.4° (1.2 g. in 25 cc. EtOH), of retronecine, m. 121°, $[\alpha]_D^{25}$ 49.3° (1.3316 g. in 25 cc. EtOH); *diacetylretronecine picrate*, yellow, m. 146°. I (10.8 g.) in 10 cc. AcOH and 40 cc. EtOH, reduced with PtO_2 and 2 3 atm. H, absorbs 2 moles H in 5 hrs., giving *monocrotalic acid* (III), $C_8H_{12}O_5$, m. 181-2°, $[\alpha]_D^{25}$ −5.33° (1.1734 g. in 25 cc. H_2O); *p-bromophenacyl ester*, m. 162 3°, $[\alpha]_D^{25.5}$ −14.1° (0.142 g. in 3.74 cc. EtOH); the other product of the hydrogenation is *retronecanol*, $C_8H_{15}ON$, b_{40} 140°, m. 95-6°, $[\alpha]_D^{25}$ −91.1° (1.524 g. in 25 cc. EtOH); *HCl salt*, m. 210° (decompn.); *methiodide*, m. 193° (decompn.), $[\alpha]_D^{27}$ −52.8° (0.473 g. in 10 cc. MeOH); *picrate*, yellow, m. 210°. Heating 5 g. of III with 30 cc. 10% aq. NaOH for 1 hr. gives II. A table of known alkaloids of the acid-alkanolamine type is given. II. **Monocrotic acid obtained by alkaline hydrolysis of the alkaloid.** Roger Adams, E. F. Rogers and F. J. Sprules. *Ibid.* 2819–21.—Monocrotic acid (I) with CH_2N_2 gives a *Me ester* (II), b_{18} 94–6°, $d_4^{25.5}$ 0.9968, n_D^{25} 1.4273, 90% yield; the *2,4-dinitrophenylhydrazone* of II m. 95-6°, 85% yield; this indicates the presence of a ketone group. I with I-KI and 10% aq. NaOH gives CHI_3, indicating an Ac group. Oxidation of I with NaOBr gives a mixt. of *meso-* (III) and *dl-α,α'*-dimethylsuccinic acids (IV). III and IV give *half anilides*, m. 169–70° and 135–6°, resp. The *p-bromophenacyl ester* of III m. 155 6°; IV yields an *anhydride*, m. 88°. These results show that I is *α,β-dimethyllevulinic acid*, $MeCHAcCHMeCO_2H$. I, heated at 240-50°, gives *α,β,γ-trimethylangelicalactone* (V), b_{20} 121°, n_D^{19} 1.4665, n_D^{19} 1.4640, d_4^{20} 1.024; V decolorizes $KMnO_4$ and gives a pos. test with Tollens reagent and with Na nitroprusside. Refluxing IV with 10% EtOH-KOH gives I. Catalytic reduction of IV at 120° and 133 atm. with Raney Ni gives *α,β-dimethyl-γ-valerolactone*, b_{20} 106 7°, n_D^{19} 1.4382, n_D^{19} 1.4348, d_4^{27} 0.987; this also results from the hydrogenation of II (7 hrs.). The formation of III and IV from I is probably due to rearrangements taking place during the reaction. III. **Monocratalic acid.** Roger Adams, E. F. Rogers and R. S. Long. *Ibid.* 2822-4.—Monocratalic acid (I) with CH_2N_2 in $CHCl_3$-Et_2O at 10° gives 97% of the *Me ester* (II), m. 79-80°, $[\alpha]_D^{19}$ −16.24° (0.502 g. in 10 cc. abs. EtOH); it contains 1 active H atom. Heating I at 200° gives *α,β,γ*-trimethylangelicalactone (III) (part II). Heating II at 200-10° until the evolution of H_2O is complete gives *Me anhydromonocratalate* (IV), b_2 115–16°, n_D^{19} 1.4700, d_4^{19} 1.131, $[\alpha]_D^{19}$ 25.74°, and a small amt. of III. Hydrolysis of IV with concd. HCl (refluxing 8 hrs.) gives III. Catalytic reduction of IV contg. III gives *α,β*-dimethyl-γ-valerolactone and the *dihydro deriv.* (V) of IV, b_1 115–17°, n_D^{19} 1.4510, d_4^{28} 0.996; pure IV gives pure V. Hydrolysis of V with concd. HCl (refluxing for 5 hrs.) gives 63% of *α-carboxy-α,β-dimethyl-γ-valerolactone*, m. 131–2°, $[\alpha]_D^{19}$ 3.80° (0.303 g. in 10 cc. abs. EtOH); *p-bromophenacyl ester*, m. 142–3°, $[\alpha]_D^{19}$ −3.89° (0.2315 g. in 5 cc. Me_2CO). The possible structure of I is discussed, with the conclusion that it is optically active *α-carboxy-α,β-dimethyl-γ-hydroxy-γ-valerolactone*, $MeCH.C(OH)Me.O.CO.C(CO_2H)Me$. C. J. West

The alkaloids of Mitragyna rotundifolia. I. Geo. Barger, E. Dyer and L. J. Sargent. *J. Org. Chem.* **4**, 418-27(1939).—On extn. of air-dried leaves of *Mitragyna rotundifolia* (Roxb.) O. Kuntze (*M. diversifolia*, Hook, f.) with 95% EtOH, 2 cryst. alkaloids, $C_{22}H_{28}N_2O_4$ (I) and $C_{22}H_{28}N_2O_5$ (II), were isolated. I m. 208–9°, $[\alpha]_D^{15}$ −14.5° (*c* 2.5, $CHCl_3$), and is identical with *mitrinermine* (cf. Raymond-Hamet and Millat, *C. A.* **30**, 1379[8]) and with *rhynchophylline* (cf. Kondo, Fukuda and Tomita, *C. A.* **22**, 3166). Hydrolysis of I with alc. KOH yields an amorphous amphoteric acid, *rhynchophyllic acid* (III), which sinters at 140° and decomps. gradually above 150°. When III is heated with CaO at 1–2 mm. at 180°, a sublimate (IV) with the formula $C_{10}H_9NO$ is obtained and at 210–30° a yellow oil is formed. IV, after recrystn. from Et_2O, sinters at 180° and m. 182–4°. IV does not contain any MeO groups and is sol. in boiling alkali. On heating with Zn dust it yields a substance which gives a pos. Ehrlich reaction. It is assumed that IV is a *Me deriv.* of *carbostyril*. Degradation of III by heating with soda-lime at 220–355° gives a mixt. of NH_3, oxygenated indoles and a pyridine-like base, a negligibly acidic, a neutral (V) and a basic fraction (VI). Redistn. of V gives 2 fractions, *A*, b_{18} 110–20°, and *B*, b_{18} 145–55°. Both resemble skatole in odor, in the pine-splinter reaction and in their behavior toward Ehrlich's reagent in the cold. *B*, when reduced with Zn dust according to Schlieper (*Ann.* **239**, 229(1887)), gives a base, b_{18} 75–85°, which gives a *picrate*, m. 140 2°, and a neutral oil, b_{18} at a bath temp of 100–38°. VI b_{18} 85–95° and gives a *picrate*, m. 123 5° after sintering at 115°. The *free base* of VI has the compn. C_8H_9NO or $C_8H_{11}NO$. Boiling of I with 30% H_2SO_4 results in a loss of CO_2. II m. 233–4°, $[\alpha]_D^{15}$ 124° (*c* 2.14, $CHCl_3$). It is stable to $KMnO_4$ but decolorizes Br in $CHCl_3$, gives with $FeCl_3$ in a non-hydroxylic solvent a deep garnet-red coloration indicating the presence of an enolic OH group. It does not react with semicarbazide. Hydrolysis of II yields amorphous *rotundifolic acid* (VII) which softens at 160°, effervesces above 165° and darkens at 170°. Distn. of VII with CaO at 200–50° at 1-2 mm. yields a cryst. base, $C_{20}H_{24}N_2O_3$, which sinters at 198° and m. 200-2°. Degradation of II with soda-lime yields a mixt. of indoles, NH_3 and pyridine-like bases. Boiling with 30% H_2SO_4 splits off CO_2. Dehydrogenation of II with Se and distn. of the C_6H_6 ext. give 3 fractions, *C* b_{11} 85–135°, *D* b_{14} 150–75° and *E* b_{14} 180-210°. *C*, on redistn., gives a base $C_9H_{13}N$, b. 195–200°, which forms a *picrate* m. 134–5°. *D* and *E* have not yet been investigated. Ultraviolet absorption measurements of I and II are compared with those of yohimbine and show less relationship to the latter than would be expected. F. E. Brauns



Lactonization of dihydro-*l*-abiatic and dihydro-*l*-pimaric acids. Elmer E. Fleck and S. Palkin. *J. Am. Chem. Soc.* **61**, 3197–9(1939).—Dihydro-*l*-pimaric acid, m. 144-6°, $[\alpha]_D^{19}$ 35°, added to 10 cc. concd. H_2SO_4 at −5° to −10° and stirred for 45 min., gives a lactone (I), m. 131-2°, $[\alpha]_D^{19}$ −4°, identical with lactonized dihydroabietic acid (*C. A.* **33**, 5405[9]); this also appears to be formed from dihydro-*l*-abietic acid with $[\alpha]_D^{19}$ 108°. Hydrolysis of I with 10% BuOH-KOH gives tetrahydroxyabietic acid (II), m. 164–5°; *Me ester*, b_2 175–80°, m. 50–1°, $[\alpha]_D^{25}$ 21°. II is conveniently prepd. by adding 1 g. I to 4 g. 88% KOH at 200° and heating for 15 min. **Oxidation and acylation expts. indicate the C-13 position**

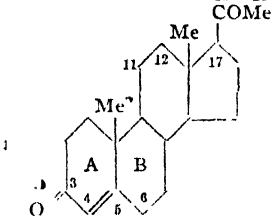
as a more probable point of lactonization than C-10. Rotations were measured in 2% EtOH soln. C. J. West

Saponins and sapogenins. XIII. The precipitability of steroid sapogenins by digitonin. C. R. Noller. *J. Am. Chem. Soc.* **61**, 2717–19(1939); cf. *C. A.* **33**, 8620[8].—In view of the extensive use of the digitonin (I) test it seemed desirable to establish a more definite criterion of compd. formation with I. The relative soly. of the compd. and its component is the only property that can be used conveniently in the steroid sapogenin series and it would seem that to show compd. formation it is necessary to show that the soly. of the digitonide is less than that of either of its components. If a soln. of cholesterol (II) or of β-cholestanol (III) in 90% EtOH, satd. at room temp., is mixed with an equal vol. of a satd. soln. of I in EtOH, a ppt. forms almost immediately. Under the same conditions tigogenin (IV) yields a ppt. after about 20 min., gitogenin (V) after 15 hrs., while sarsasapogenin (VI), chlorogenin (VII), epicoprosterol (VIII) and epidihydrocholesterol (IX) give no ppt. after standing for 5 days. If, however, the solns. of the last 4 compds. are concd. to half vol. to bring the concn. of the compd. and of I to that of satd. solns., all except VIII give some ppt. after standing for 5 hrs. It is seen, therefore, that neither condition gives a satisfactory test since before concn. VI, which is known to give a less-sol. digitonide than its epimer, did not ppt. whereas after concn. IX, which has the α-configuration, also was pptd. The soly. in 90% EtOH (g. per 5 cc.) was detd. as follows: I 0.0412, III 0.0174, IV 0.0051, V 0 0181, VI 0.0170, VII 0.0404, VIII 0.0524, IX 0.0120. The soly. of the digitonides of steroid sapogenins varies considerably and is much greater than that of those of II and III. Thus the soly. product of the digitonide of VI, which is known to be the less-sol. of 2 epimeric forms, is practically the same (9.7×10^{-6} mole per l.) as that of the digitonide of IX (9.4×10^{-6}), which ordinarily is considered as not precipitable by I. V digitonide has a smaller soly. product (4.7×10^{-6}) than VI and hence V provisionally must be considered as being the epimer that is pptd. by I. The digitonide of VII has a much larger soly. product (3.1×10^{-5}) than that of VI and until its epimer is prepd. and shown to give a more-sol. digitonide, VII must be considered as the isomer not precipitable by I. The soly. product of IV is 1.6×10^{-7}; those of I and II are small and that of VIII is large. The soly. products of steroid digitonides vary so widely that qual. tests for pptn. are without meaning unless the behavior of both isomers can be compared. **XIV. The so-called pyridazine derivatives of steroid diones.** *Ibid.* 2976–7.—Marker and Rohrmann (*C. A.* **33**, 4263[4]) postulated that the HO groups of chlorogenin (I) occupy the 3,6-positions in the sterol nucleus on the basis of the formation of a pyridazine deriv. (II) (Noller, *C. A.* **31**, 5368[3]). Three prepns. of II showed mol. wts. of 1410, 1980, 2770 (calcd. for a monomol. compd. 425). It is evident, therefore, that the formation of condensation products with N_2H_4 does not prove that the HO groups of I are in the 3,6-positions, although the fact that the condensation products are polymol. does not exclude these positions. The so-called pyridazine deriv. of cholestane-3,6-dione, amorphous, m. 210–20°, showed a mol. wt. in freezing C_6H_6 of 2999 (calcd. 396). C. J. West

Porphyrin studies. III. The structure of the porphine ring system. Paul Rothemund. *J. Am. Chem. Soc.* **61**, 2912–15(1939); cf. *C. A.* **30**, 3833[3].—In the prepn. of porphine (I) from pyrrole and HCHO, it was observed that there was present a porphyrin with a HCl no. of 0.5; this is designated *isoporphine* (II); details of the sepn. of II are given; recrystd. from C_5H_5N-Et_2O (1 + 9 vols.) it decomps. above 250°. Proposed formulas for I and II and their Mg complexes are given but their designations are arbitrary at present. The *Mg salt* of II (*isoporphine phyllin*), $C_{20}H_{12}N_4Mg$, is not stable when heated with 5% HCl on the steam bath. The *hemin* and the *Cu salt* of II are also reported. Absorption spectra are given for II in Et_2O, the Mg salt in Et_2O and in alk. reaction mixts. and for the hemin and Cu salt in C_5H_5N-Et_2O and as chart gives the values for I and its corresponding salts. In view of this isomerism of I and II the synthesis of α,β,γ,δ-tetrasubstituted porphines (part II) was checked with respect to a possible formation of 2 isomers. The following HCl nos. were found: I and II 3.3 and 0.5; tetra-Me deriv. 0.5 and 0.075; tetra-Pr deriv. about 8, 2.3; tetra-Bu deriv. about 14, 7; tetraiso-Bu deriv. ?, 5.2; tetra-Ph deriv. 13.5, 8.5; tetrakis(3-methoxy-4-hydroxyphenyl) deriv. 1.04, 0.45; tetrakis(*o*-hydroxyphenyl) deriv. 15.7, ?; *m*-isomer 6, 12.2; *p*-isomer 4, 16.8 (the ? indicates that purification has not been sufficient to det. the HCl no.). C. J. West

The constitution of the prosthetic group of cytochrome c. K. Zeile and H. Meyer. *Naturwissenschaften* **27**, 596–7(1939).—From cytochrome c, hematoporphyrin and mesoporphyrin were prepd. (*C. A.* **28**, 185[4]). A further study was made of the side chains which tend to make porphyrin from cytochrome hydrophilic. Resynthesis such as found by Theorell (*C. A.* **33**, 188[6], 8638[7]) was avoided in the decompn. of the cytochrome by use of very low cytochrome concns.; the products were fractionated by use of an org. solvent and water of varying pH. A dicysteine-protoporphyrin was prepd. from protoporphyrin with HBr melted together with *l*-cysteine-HCl in order to study the qualities of such a S compd. (mol. wt. 860.6) as a tetra-Me ester, $C_{44}H_{56}N_6S_2O_8$. After sapon. of cytochrome c in 2×10^{-5} *M* soln., methylation and fractionation, 65% of an ester fraction was obtained which seemed to have the same properties as the synthetic substance according to previously worked-out tests (Z. and Rau, *C. A.* **32**, 2964[1]). It apparently is $C_{44}H_{56}N_6S_2O_8.H_2O$ (mol. wt. 878.6). The natural compd. in 0.1% HCl at 17°, white light, has a specific rotation of −172°, the synthetic product 27°. This difference is readily understood considering the no. of possible stereoisomers of protoporphyrin-HBr. The absorption spectra of the 2 compds. agree. The structure of the tetra-Me ester is

(R = $CH_2CH(NH_2)CO_2H$) for the half-mol. The Fe complex salts of the natural or the synthetic compd. give hemochromogens upon reduction, which have principal absorption bands corresponding to those of natural cytochrome c. No addn. of N base is required for this absorption; it takes place in neutral soln. In this hemochromogen evidently all 6 coördination places of the Fe are occupied by N from the mol. itself: 4 by pyrrole N, 2 by amino N. It was shown that the NH_2 groups are not on the Fe of neighboring mols. B. J. C. v. d. H.



The melanoidins and their relation to humic acids. Curt Enders and Karl Theis. *Brennstoff-Chem.* **19**, 360–5, 402–7, 439–49(1938); cf. *C. A.* **31**, 4048[1], 5100[4]; **32**, 2285[3]; **33**, 3660[3].—The literature is reviewed with particular regard to observations of the similarity of these substances. Details of the prepn. of a standard melanoidin from glycine and glucose by an unpublished method of E. and Emmerich, its properties, colorimetric detn. in aq. soln., kinetics of formation and relation of pH thereto are described in detail. Elementary analysis of the prepn. dried at 105° corresponded to $C_{67}H_{76}O_{32}N_8$. The mol. contains 5 carboxyl groups, a small no. of double bonds, 8 alc. OH groups, 3 phenolic OH groups and 2 carbonyl groups, and a MeO content of 17.07%. In a series of coalifications of the prepn., at 150° and 1 at 220° for 1–6 hrs. progressive changes indicating aromatization were noted. This occurred more readily than with brown coal humic acids. Oxidation of the prepn. with HNO_3 gave first a H_2O-insol. material sol. in acetone. Stronger acid produced material conforming to $C_8H_{14}O_8N_4$, m. 156°, and oxalic, glycolic, succinic, picric and dihydroxybenzenedicarboxylic acids. Oxidation with H_2O_2 produced NH_3 and formic, glycolic, acetic, succinic and possibly tartaric

acids. The action of ClO_3 did not produce maleic acid. F. W. Jung

The connection between bitter taste and chemical constitution. Charonnat. *Union pharm.* **1939**, 27.—3,7,12-Triacetoxycholanic acid is more bitter than the tri-HO acid. 7,12-Diacetoxycholanic acid is not bitter. The Ac group at position 3 necessary for a Legal aceto-reaction, —CO— or CHOH between 2 secondary C atoms causes bitterness if the compd. is sol. Glucosides, cardiotonics and related saponins, cyclohexanol, cyclohexanone, glycyrrhetic acid (alc. group next to a quaternary C) cholatrienic acid (no alc. group) are not bitter. J. McAfee

Sterols. LXXII. Urane derivatives. Russell E. Marker and Ewald Rohrmann. *J. Am. Chem. Soc.* **61**, 2719-22(1939). Cf. *C. A.* **33**, 8621[6].—Uranc-3,11-dione (I) forms a *Br deriv.*, m. 202-3° (decompn.); refluxing with C_5H_5N for 3.5 hrs. gives a *pyridinium salt*, does not m. 300°; heating this salt at 5–10 mm. gives *urenedione*, m. 168–70°. Reduction of I with (iso-PrO)$_3$Al in iso-PrOH or catalytically in EtOH with the Adams catalyst (2 hrs. at 25°) gives *uran-3(β)-ol-11-one* (II), m. 205–7° (*acetate*, m. 170.5–2°); the epi fraction was not investigated. II also results on oxidation of urane-3(β),11-diol with CrO_3 in AcOH at room temp. II does not form a semicarbazone. Refluxing uranediol with (iso PrO)$_3$Al in cyclohexanone-toluene for 10 hrs. gives a small yield of *uran-11-ol-3-one*, m. 169.5–71°; *acetate*, m. 195–7°; *semicarbazone*, m. 251.3° (decompn.). Reduction of I with Zn and HCl in EtOH gives a quant. yield of *uran-11-one*, m. 135–6.5°; this does not form a semicarbazone; catalytic reduction yields *uran-11-ol*, m. 110° (*acetate*, m. 140.2°). If amalgamated Zn is used in the reduction of I the main product is urane. Mild Clemmensen reduction of uranetrione yields *urane-11,20-dione*, m. 199–201°. **LXXII. Oxidation products of sarsasapogenin. C_{19} dibasic acid.** *Ibid.* 2722-4.—The hydrolyzed acidic fraction obtained from the oxidation of sarsasapogenin acetate (*C. A.* **33**, 5107[5]) with twice its wt. of CrO_3 at 85° was taken up in Et_2O, the C_{22} keto acid allowed to sep. and the filtrate evapd. to a sirup; addn. of $CHCl_3$ ppts. the *dibasic acid* $C_{19}H_{30}O_5$ (I), m. 220-2°; this was also obtained in nearly 12% yield by oxidation of sarsasapogenoic acid (II) acetate at 90-5° with CrO_3 and in poor yield from the CrO_3 oxidation at 90-5° of the acetylation product of tetrahydrosarsasapogenin in C_5H_5N in the cold. Refluxing I with Ac_2O for 30 min. gives the *acetate anhydride*, $C_{23}H_{30}O_6$, m. 203–4°; it also results from Ac_2O and C_5H_5N after 20 hrs. at room temp.; EtOH-KOH gives I. CH_2N_2 gives the *di-Me ester* of I, m. 121-2°, whose *acetate* m. 103-4°. Oxidation of I with CrO_3 in AcOH at room temp. for 1 hr., followed by Clemmensen reduction, yields the *desoxy acid* (III), $C_{19}H_{30}O_4$, m. 230-2°; this also results from oxidation of desoxysarsasapogenin with CrO_3 at 90–5°. Refluxing III with Ac_2O for 30 min. and sublimation at 120–40° give the *desoxy anhydride*, $C_{19}H_{28}O_3$, m. 205.5–7°. I is probably 3-hydroxyetiobilianic acid. The fact that II is oxidized easily to I suggests that it is an intermediate in the oxidation of sarsasapogenin to the bilianic acid. III is very probably identical with etiobilianic acid (Wieland, Schlichting and Jacobi, *C. A.* **21**, 590). **LXXIII. Reactions of digitogenin and gitogenin.** *Ibid.* 2724-6.—The filtrate after removal of chlorogenin and tigogenin from *Chlorogalum pomeridianum* was evapd. to dryness, acetylated and recrystd. from Me_2CO, giving the diacetate (I), m. 241–3°, of gitogenin (II), m. 266–8°. I is not affected by boiling with Zn-Hg and HCl in AcOH for 6 hrs. Digitonin (III) (50 g.), boiled in 500 cc. MeOH, 100 cc. H_2O and 100 cc. concd. HCl for 8 hrs., gives digitogenin (IV), m. 278°; this is recovered essentially unchanged after treatment with Zn-Hg and HCl in EtOH for 5 hrs. I in glacial AcOH with the Adams catalyst and H (3 atm.) for 12 hrs. at 70°, followed by hydrolysis, gives *dihydrogitogenin*, m. 195–7°; it gives a ppt. with III, does not react with SeO_2 and yields a *tri-p-nitrobenzoate*, pale yellow, m. 189–91°. IV yields a *dihydro deriv.*, m. 184–6°. I and Br in AcOH contg. a little HBr give a *Br deriv.* (V), m. 219–20°; reduction with Na and abs. EtOH gives II; V does not react with SeO_2 in AcOH. *Bromodigitogenin triacetate*, m. 142° (decompn.). The triacetate of IV and CrO_3 in AcOH at 95° (CrO_3 added during 1 hr. and the product heated an addnl. 90 min.) give *digitogenin lactone triacetate*, m. 281-3°; hydrolysis with EtOH-KOH gives the *tri-HO lactone*, $C_{32}H_{34}O_8$, m. 279–82°. *Gitogenin lactone diacetate*, m. 248–51°; the *lactone* m. 276-8° and forms a *dibenzoate*, m. 275–8°. Both II and IV yield insol. digitonides. **LXXIV. Acetic acid derivatives of estrone and α-estradiol.** *Ibid.* 2974.—Estrone (I) and $ClCH_2CO_2Et$ with EtONa (refluxed 14 hrs.) give 1,3,5-estratrien-17-one-3-hydroxyacetic acid, m. 209–11°; *oxime*, m. 230–2° (decompn.); *Me ester*, m. 130–2°. 1,3,5-Estratriene-3,17(α)-diol gives *1,3,5-estratrien-17(α)-ol-3-hydroxyacetic acid*, m. 182-4°; *Me ester*, m. 94-6°. I and $MeCHClCO_2Et$ give *1,3,5-estratrien-17-one-3-hydroxymethylacetic acid*, m. 195–8°; *Me ester*, m. 137–9. **LXXV. Cholesterol derivatives.** *Ibid.* 3022-4.—7-Ketocholesteryl chloride in Et_2O, shaken with H at 3 atm. for 4 hrs. at 25° (Adams catalyst), gives 7-ketocholestyl chloride, m. 136–8° (*oxime*, m. 152–4°). Reduction of the acetate of 5-cholesten-3(β)-ol-7-one in Et_2O gives the *acetate* (I), m. 147–8°, of *cholestan-3(β)-ol-7-one*, m. 128–30° and then 157–9° (*oxime*, m. 232–3°). Catalytic reduction of 7-ketocholesteryl acetate in AcOH with the Adams catalyst and hydrolysis of the reduction product yield cholestane-3(β),7(α)-diol, m. 164-6°; this also results from I and (iso-PrO)$_3$Al in iso-PrOH on refluxing 14 hrs. 7-Hydroxycholesteryl chloride with Na in AmOH gives 5-cholesten-7-ol (II), m. 105–6°; benzoate, m. 145–7° (Dimroth and Trautmann (*C. A.* **30**, 4506[4]) give 93.4° and 108-9°, resp.); catalytic reduction gives cholestan-7-ol. Bromination of II followed by mild oxidation with CrO_3 and subsequent debromination give *5-cholesten-7-one*, m. 125–6°. Cholesteryl acetate in C_6H_6 and SeO_2 in 98% AcOH give *3-acetyl-4-hydroxycholesterol*, m. 163–5°; the AcOH filtrate deposits a polymorphic form, m. 189–91°; both forms give the same diacetate, m. 162–3°. C. J. West

Steroids. I. 6-Oxoprogesterone and the stereochemical configuration of several 3,5,6-triols. Maximilian Ehrenstein. *J. Org. Chem.* **4**, 506–18(1939).—Introduction of an OH group into the side chain at C atom 21 as in 21-hydroxyprogesterone causes a decrease in the progestational and an increase in the "cortin" activity. No systematic attempt has been made to exam. progesterones with OH groups in the ring system except 1,2-hydroxyprogesterone (cf. Ehrhart, Ruschig and

Aumueller, *C. A.* **33**, 6327[8]), and this has apparently not been examd. for "cortin" action. To investigate the physiol. properties of these progesterones oxygenated in the ring, 6-oxoprogesterone (I) is prepd. Butenandt and Riegel (*C. A.* **30**, 5234[6]) prepd. 6-oxotestosterone acetate and 4-androstene-3,6,17-trione (II) by oxidizing 5-androstene-3,17-diol 17-monoacetate and dehydroisoandrosterone (III), resp., with Cr_2O_3 in AcOH, but they do not show androgenic properties. In addn. to these compds. a white cryst. substance is obtained which they consider to be a hydrate of the resp. 6-oxo compds. On the other hand, Ushakov and Lyutenberg (*C. A.* **32**, 1871, 5774) subjected III to a series of reactions and obtained a compd. which is presumably identical with II. Since no definite comparison of these substances has been made E. reinvestigates the various oxidations of

III. III (200 mg.), in 6 cc. AcOH and 280 mg. Cr_2O_3 in a few drops H_2O and addnl. 3 cc. AcOH, is shaken for 7 hrs. at 29°, dild. with H_2O and extd. with Et_2O. The Et_2O exts. are washed with 2 *N* Na_2CO_3, dried with Na_2SO_4 and evapd. The yellow partially cryst. residue is extd. with C_6H_6, concd. *in vacuo* and the residue treated with EtOH, which leaves the white cryst. product partially undissolved. The part which is dissolved in the EtOH is recovered by concn. The total white cryst. product is recrystd. from hot EtOH, from which 1.8 mg. *androstane-3,6,17-trion-5-ol* (IV) is obtained, which m. 248–9° in agreement with B. and R., $[\alpha]_D^{23}$ 54.6° (Me_2CO). II is not isolated. IV is also obtained from *dehydroisoandrosterone acetate* (V) which in turn is prepd. by acetylation of III with pyridine and Ac_2O. V m. 171–2°. Oxidation of 200 mg. V by heating it with 0.2 cc. 30% H_2O_2 in 1 cc. AcOH gives 48.7 mg. *androstan-17-one-3(β),5,6-(trans)-triol* (VI), m. 295–8°. When 50 mg. VI is oxidized with 37.5 mg. Cr_2O_3 in 5.5 cc. AcOH at room temp. for 22 hrs. and 2 cc. EtOH is added and the mixt. then concd. *in vacuo*, 22.1 mg. IV, m. 249.5–50.5°, is obtained after recrystn. from EtOH. From the mother liquor another 3.9 mg., m. 247–8.5°, $[\alpha]_D^{25}$ 62.2° (4.5 mg. in 2 cc. Me_2CO), is isolated. The identity of U.'s and B.'s compds. is therefore established. U. and L. oxidized III with OsO_4 according to Criegee (*C. A.* **30**, 3811[1]) and obtained *androstan-17-one-3(β),5,6(cis)-triol* (VII) which they claimed is different from VI and it is interesting to det. the actual configuration of the OH groups at C atoms 5 and 6. Since oxidation of VI and VII both give IV, the configuration of the OH at C atom 5 is the same and the assignment of a definite configuration to C atom 5 would automatically fix the configuration at C atom 6 (cf. Butenandt and co-workers, *C. A.* **33**, 5862[8], and Westphal, *et al.*, *C. A.* **33**, 7306[4]). U. and L.'s expt. is repeated by treating 350 mg. III with 350 mg. OsO_4 in 53 cc. abs. Et_2O. The mixt. is kept at 28–30.5° for 3 days, the Et_2O evapd. and the soln. of 2.5 g. Na_2SO_3 in 25 cc. 95% EtOH and 50 cc. H_2O is added and the mixt. refluxed for 2.5 hrs. The filtered soln. is concd. *in vacuo*, satd. with NaCl and extd. 4 times with $CHCl_3$. The $CHCl_3$ ext. is washed with H_2O, dried and evapd. From the residue 133.5 mg. VII, m. 243–5.5°, $[\alpha]_D^{25}$ 79.5° (19 mg. in 2 cc. MeOH), is obtained. When 100 mg. VII is oxidized in 8 cc. AcOH and 75 mg. Cr_2O_3 in 3 cc. AcOH at room temp. for 18.5 hrs., 38.9 mg. IV, m. 249–50.5° (decompn.), is formed. In the derivs. of III in which the OH group at C atom 3 is covered by AcO, the 5,6-double bond is inert to the addn. of OsO_4. Since the OH group at C atom 3 in these compds. is in the β-position, esterification of the OH group should sterically hinder the addn. of OsO_4 provided that the latter leads to a cis linkage of rings A and B. Expts. analogous to those with III have been carried out on 5-pregnen-20-on-3-ol (VIII). Oxidation of 396.2 mg. VIII in 15 cc. AcOH with 506 mg. Cr_2O_3 in a trace of H_2O and 3 cc. AcOH at 27° for 5.5 hrs. gives 38.7 mg. *pregnane-3,6,20-trion-5-ol* (IX) m. 267–8°. IX is also obtained from *5-pregnen-20-on-3-ol acetate* (X), prepd. by acetylation of VIII with Ac_2O and pyridine, m. 144.5–6.5°. X (400 mg.) is first oxidized with H_2O_2 in AcOH to give *pregnan-20-one-3(β),5,6(trans)-triol* (XI), m. 256–8°. Oxidation of XI with Cr_2O_3 in AcOH gives IX. IX is also identical with a product which is obtained from VIII via *pregnan-20-one-3(β),5,6(cis)-triol* (XII). To a suspension of 340 mg. VIII in 27 cc. Et_2O 310 mg. OsO_4 in 31 cc. Et_2O is added, giving 341.5 mg. of a mixt of XII and unchanged VIII, m. 190°. It is therefore retreated with OsO_4 in dioxane and gives then 170.3 mg. XII, m. 231–2.5°, $[\alpha]_D^{25}$ 59.8° (14.8 mg. in 2 cc. MeOH). Oxidation of XII with Cr_2O_3 gives IX, m. 267–8.5°. The prepn. of an identical trione from either X or XII proves that the 2 triols have the same configuration at C atom 5. Since VIII has the same β-configuration at C atom 3 as III, its acetate is inert toward OsO_4. When IX is dehydrated in $CHCl_3$ with dry HCl, *4-pregnene-3,6,20-trione* (*6-oxoprogesterone*) (XIII) is formed, m. 185–8°. When X is treated with OsO_4 in Et_2O, chiefly VIII is recovered, which on acetylation gives X again. The ultraviolet absorption curve of XIII has been detd. A biol. test on mice shows a moderate estrogenic reaction. F. E. B.

Steroids. XXIII. Homologs of sex hormones. 1. K. Miescher and A. Wettstein. *Helv. Chim. Acta* **22**, 1262–8(1939); cf. *C. A.* **29**, 6898[8]; **33**, 8208[1].—Since androstenedione, regarded as the lowest homolog of progesterone, is the prototype of a strongly androgenic hormone, and 17-methyltestosterone (I), a homolog of testosterone, is one of the most potent androgens, a new homolog of testosterone, *Δ⁴-17-hydroxymethylandrosten-3-one* (II), was prepd. It is an isomer of I. Starting with the reduction of Me 3-hydroxy-5-etiocholenate (III) (cf. *C. A.* **32**, 947[8], 7922[1]), the method of Ruzicka and Jacobs, employed in the polyterpene series (cf. *C. A.* **32**, 7441[4]), was used. The resulting *Δ⁵-17-hydroxymethylandrosten-3-ol* (IV), $C_{20}H_{32}O_2$, m. 209–11° (cor.), gave a *diacetate*, $C_{24}H_{36}O_4$, m. 136–7°. For its oxidation 1.015 g. of IV was suspended in 20 cc. glacial AcOH and 0.533 g. Br in 13.5 cc. glacial AcOH was added with cooling. After addn. of 0.5 g. Cr_2O_3 in 5 cc. 90% glacial AcOH and agitation for 16 hrs. the soln. was heated for 10 min. with 5 g. Zn dust at 70–80°, cooled and filtered. The filtrate was poured into water and extd. with ether, washed with *N* alkali, dried and evapd. This fraction is still under study. The alk. eluates of the ether ext. were acidified, the pptd. acid fraction was extd. with ether, the ext. washed and dried and a soln. of CH_2N_2 in ether was added. On standing at room temp. until the evolution of N ceased the ether ext. was shaken with *N* soda (?) soln. and water, dried and evapd. The residue was treated with Girard's reagent (cf. *C. A.* **31**, 1006[4]) and, recrystd. from hexane, gave *Me Δ⁴-3-ketoetiocholenate* (V), $C_{21}H_{30}O_3$, m. 134–5°. The same compd. was obtained also by boiling 1 g. of III for 2.5 hrs. with 1 g. (iso-PrO)$_3$Al, 50 cc. toluene and 8 cc. cyclohexanone, and sepg. the ketonic portion from the nonevaporable part of the product according to Girard. The V was sapond. by boiling 4 hrs. with 7% KOH in MeOH. The mixt. was poured into water, extd. with ether, the aq. phase freed from ether by heating, acidified and the flocculating *Δ⁴-3-ketoetiocholenic acid* (VI) purified by sublimation at 220° (0.001 mm.) and recrystn. from dil. acetone, giving $C_{20}H_{28}O_3$, m. 258–62°. For dehydration 1.4 g. of IV was refluxed for 1.5 hrs. with 80 cc. of toluene, 1.6 g. (iso-PrO)$_3$Al and 12 cc. cyclohexanone. After steam distn. of the mixt. for 2 hrs. the residue was acidified with 2 *N* H_2SO_4, extd. with ether, the ext. shaken out with 40% bisulfite soln., water, *N* soda (?) soln. and water. On evapn., the residue was treated with Girard's reagent and a ketonic fraction (1.27 g.) obtained. This was heated 5 hrs. with 2.5 g. of anhyd. succinic acid and 12.5 cc. pyridine. On cooling the soln. was poured into 100 cc. of 2 *N* soda (?) soln. and exhausted with ether. The ext. (HO-free ketonic fraction) was washed with dil. H_2SO_4 and water, dried and evapd. The residue was dissolved in hexane-benzene (3:1) and chromatographed on Al_2O_3. After elimination of a sticky fraction the recrystd. compd. yielded a by-product, $C_{26}H_{36}O_2$, m. 190–93°. The alk. soln. of the succinic acid ester was acidified and exhausted with ether. The ether soln. was washed with dil. acid and water, dried and evapd. *in vacuo*. The residue was heated with 2% KOH in MeOH, the sapond. soln. poured into water, extd. with ether, the exts. were washed, dried and evapd. The ketone-alc. fraction (1 g.) was dissolved in hexane-benzene (1:1), filtered through a 30-g. column of Al_2O_3 and washed with 500 cc. of the hexane-benzene mixt. The final product (II) was extd. by benzene-ether (1:1) and crystd. from dil. acetone; $C_{20}H_{30}O_2$, m. 158–9°; *acetate*, $C_{22}H_{32}O_3$, m. 114–15°; *acetate semicarbazone*, $C_{23}H_{35}O_3N_3$, m. 214–15°. On oxidation with Cr_2O_3 at room temp. II gave VI. Its physiol. action will be described later. T. Laanes

Chemical constitution of cholesterol. Isomerization with hydrobromic acid. Francesco Pirrone. *Ricerca sci.* **10**, 416–21(1939); cf. De Fazi, *C. A.* **32**, 6660[8].—An alc. soln. of 30 g. of cholesterol (I), with neg. Rosenheim reaction, was added at ordinary temp. to

200 cc. of 24% HBr. Spontaneous evapn. gave a cryst. solid m. 130–135°, which by crystn. from EtOH gave an *isomer* (II) of I, m. 138.5–9°, slightly sol. in alc., and 2 other fractions (III and IV) in small amt., m. 125° and 104–5°, resp. A mixt. of I and II m. 125–30°. II gave no Rosenheim reaction within an hr.; the Salkowski reaction gave a yellow color in $CHCl_3$, changing to blood-red; the Liebermann reaction was immediate and permanent. II had the compn. $C_{27}H_{46}O$, $[\alpha]$ −32° (2.125% in C_6H_6). To a soln. of 1 g. of II in 10 cc. of Et_2O was added 4 cc. of a 10% soln. of Br in HOAc. The *dibromide* (V), crystd. from Et_2O and Me_2CO, m. 97° and gave pos. tests in the above reactions. Upon debromination by KOAc in alc. V gave I, as shown by the mixed m. p. 146–8°. With boiling Ac_2O, II gave an Ac deriv., m. 113–14° after crystn. from Me_2CO, $[\alpha]$ −40.13° (2.06% in $CHCl_3$). This was shown to be identical with the Ac deriv. of I by mixed m. p. and hydrolysis to I. The same Ac deriv. was formed by treating II with Ac_2O and P_2O_5 at 7 8°. From 1 g. of II and 5 cc. of HCO_2H after boiling 3 hrs. a *formyl deriv.*, m. 84–6°, was obtained by crystn. from Me_2CO, $[\alpha]$ −46.27° (2.25% in $CHCl_3$). The color reactions of this substance were the same as those of I. From 2 g. of II with 2 g. of Bz_2O and 50 cc. of alc. was obtained after 2 hrs. boiling a *Bz deriv.* of II, m. 143–4°, $[\alpha]$ −13.94° (2.15% in $CHCl_3$), which on saponn. with alc. KOH gave I, m. 147–8°. Satn. of a soln. of 2 g. of II in 30 cc. of alc. and 30 cc. of Et_2O with dry HCl gave the *hydrochloride* of II, m. 118–20° (decompn.). After crystn. from alc. III and IV were obtained in too small amt. for study. An Osram lamp immersed in a C_6H_6 soln. of II lowered the m. p. of II in 2 hrs. to 125–8°, in 8 hrs. to 120–5°, in 24 hrs. to 76–8°, with bright-blue Rosenheim reaction. These mixts. were sepd. into unchanged II, one fraction from Me_2CO m. 102–3°, and one m. 85–7°. The latter two gave a violet-blue color in the Rosenheim reaction.

W. F. Bruce

Stigmasterol 22,23-dibromide. Erhard Fernholz and Homer E. Stavely. *J. Am. Chem. Soc.* **61**, 2956–7 (1939).– Stigmasteryl acetate tetrabromide (5 g.) in 75 cc. C_6H_6 and 3 g. NaI in 25 cc. EtOH, allowed to stand 20 hrs. at room temp., give 60% of the *acetate*, m. 212–13°, $[\alpha]_D^{25}$ 30° (15.3 mg. in 2 cc. $CHCl_3$), of *stigmasterol 22,23-dibromide* (I), m. 209–10°. Refluxing 3.6 g. of I and 5 g. (*tert*-BuO)$_3$Al in 150 cc. C_6H_6 and 40 cc. Me_2CO overnight gives 2.6 g. of *stigmastadienone 22,23-dibromide* (II), m. 182–4°, $[\alpha]_D^{25}$ 53° (18.8 mg. in 2 cc. $CHCl_3$). Reduction of 200 mg. of II with Zn and AcOH (heating 1 hr. on the water bath) gives 45 mg. of *stigmastadienone* (III), m. 124–5°, $[\alpha]_D^{25}$ 63° (27.7 mg. in 2 cc. $CHCl_3$); *semicarbazone*, m. 235–7°. III also results from stigmasterol (IV) with (iso-PrO)$_3$Al in cyclohexanone and PhMe on refluxing 2 hrs. (cf. *C. A.* **32**, 4174[8]). Marker and Wittle's stigmastenone (*C. A.* **32**, 949[5]), prepd. from IV by catalytic dehydrogenation with Cu, should be III, but it m. 94°; no explanation of the difference is given.

C. J. West

Lignin and related compds. (Dorland, *et al.*) **23.** Azo dyes and their intermediates (Ruggli, Leupin) **25.** Procyanines (Calzavara) **5.** Distribution of astaxanthin in the animal and plant kingdom (Kuhn, *et al.*) **11A.** Electron-diffraction investigation of the mol. structures of the meso and racemic 2,3-dibromobutanes (Stevenson, Schomaker) **2.** Stability of the valency angles of the C tetrahedron—dipole moments of stereoisomeric 2,3-dichloro-2-butenes (Mikhailov, Tishchenko) **2.** Ellipsoids of polarization of bonds and octets (Wang) **2.** Dipole moments and structures of certain nitro compds. and amines (Lewis, Smyth) **2.** Substances of a green alga which det. sex (Kuhn, *et al.*) **11D.** Catalysts [for the conversion of CO and H to CH_4] (Brit. pat. 517,419) **18.**

Separating hydrocarbons. I. G. Farbenind. A.-G. (Richard Gerlach, inventor). Ger. 679,088, July 28, 1939 (Cl. 26*d*, 10.10). Addn. to 677,864 (*C. A.* **33**, 9602[2]). Gases contg. hydrocarbons are passed through a tower contg. a mixt. of liquid hydrocarbons to sep. the low-boiling constituents from the high-boiling ones. Thus, a mixt. of ethane, propane and butane is washed with a mixt. of propane and butane to sep. the ethane, which goes off unchanged in the vapor phase.

Catalytic dehydrogenation of hydrocarbons, as in producing butylenes from butane. Aristid V. Grosse (to Universal Oil Products Co.). U. S. 2,172,534, Sept. 12. In the dehydrogenation of hydrocarbons by subjecting them to dehydrogenating conditions in the presence of a mixt. of Al_2O_3 with a minor proportion of a dehydrogenating catalyst of greater activity such as Cr_2O_3, a relatively small amt. of an alkali metal oxide such as that of Na is incorporated into the Al_2O_3 prior to the addn. to it of the dehydrogenating catalyst mentioned, and serves to lessen C deposition.

Oxidation of paraffin hydrocarbons. Wilhelm A. Farenholtz, Gustav Hubbe and Herbert Hubbe (trading as Vereinigte Oelfabriken Hubbe & Farenholtz). Brit. 507,521, June 16, 1939. Paraffins that are liquid under the conditions of treatment are oxidized in the presence of salts of metals of the 6th, 7th or 8th group of the periodic system together with free higher carboxylic acids, e. g., fat (stearic or linoleic), resinic or naphthenic acids, if desired with the addn. of compds. (fat or resinic acid salts, carbonates or bicarbonates) of the alkali or alk.-earth metals, Mg included. Mn or Co oxalate, palmitate or stearate, Co resinate, Fe naphthenate, $MnCl_2$, $FeCl_3$, bichromates and U nitrate are suitable salts.

Aromatic hydrocarbons from aliphatic hydrocarbons. Aristid V. Grosse and Jacque C. Morrell (to Universal Oil Products Co.). U. S. 2,172,535, Sept. 12. For the production of aromatic hydrocarbons from aliphatic hydrocarbons contg. 6–12 C atoms, they are heated to about 400–700° for about 0.1–20 sec. in the presence of a mixt. of oxides of V, Cr and Mo. Cf. *C. A.* **33**, 6338[3].

Aromatic hydrocarbons from aliphatic alcohols. Vasili I. Komarewsky (to Universal Oil Products Co.). U. S. 2,172,540, Sept. 12. For producing aromatic hydrocarbons, such as toluene, from aliphatic alcs., such as heptyl alc., contg. at least 6 C atoms in straight chain arrangement, the alc. is brought into contact, at a dehydrating and dehydrogenating temp. (suitably about 300–500°) with a mixt. of a dehydrating catalyst such as activated alumina and a dehydrogenating catalyst such as an oxide of Cr, Mo, V or W.

Unsaturated hydrocarbons; chlorinated hydrocarbons. I. G. Farbenindustrie A.-G. Brit. 508,417, June 30, 1939. Paraffins or olefins having 3–8 C atoms per mol., or their partially chlorinated derivs., are hydrogenated by exposure in the gas phase to a temp. of 500–800° in admixt. with 0.3–2 mol. proportions of Cl per mol. of hydrocarbon, the reaction products being stabilized by cooling and then treated to sep. the dehydrogenation products. In a modification, the cooled mixt. is treated with more Cl to form Cl addn. products of the olefins produced, and the olefin chlorides may then be converted to diolefins, e. g., as described in Brit. 484,660 (*C. A.* **32**, 7353[7]). The materials to be dehydrogenated are mixed intimately with the Cl and, if desired, with dilg.-gases, e. g., chlorinated hydrocarbons, N, H_2O-vapor, CO_2. Filler bodies and catalysts may be used.

Polymerizing olefins. Standard Oil Development Co. Brit. 507,439, June 14, 1939. In polymerizing olefins with H_2SO_4 to produce dimers and trimers, the yield of dimer is increased by adding trimer to the polymerizer feed. The process is particularly applicable to the copolymerization of *n*- and iso-butenes with H_2SO_4 of 60–75% concn. at 150–300°F. and 200–600 lb. per sq. in. pressure to maintain the liquid phase. App. is described.

Polymerizing unsaturated hydrocarbons such as ethylene, propylene and butylenes. Emil Keunecke and Wilhelm Muench (to I. G. Farbenindustrie A.-G.). U. S. 2,173,482, Sept. 19. For the production of liquid hydrocarbons by polymerization, low-mol. unsatd. hydrocarbons are brought into contact with a catalyst comprising a polymerization-promoting agent such as H_3PO_4 which is applied to an activated wood charcoal having,

at a grain size of from 2 to 4 mm., a filling wt. of at the most 20 g. per 100 cc. of filling volume. Several examples with details are given.

Olefin oxides. I. G. Farbenindustrie A.-G. Brit. 507,538, June 16, 1939. In the production of olefin oxides by oxidation of olefins with O, the catalyst consists of Ag contg. a metal of the Pt group with or without other metals or compds. known as addns. to Ag catalysts for this reaction. Among examples, solns. of $AgNO_3$ and H_2PtCl_6 are dropped into a soln. of $(COONH_4)_2$ and KOH and the ppt. is boiled in glycol, washed and dried in O at 450°; a mixt. of C_2H_4 and air with or without steam is led over this catalyst at 300–320°. Cf. *C. A.* **33**, 5865[5].

Hydrating olefins to produce alcohols. Herbert G. Tanner (to E. I. du Pont de Nemours & Co.). U. S. 2,173,187, Sept. 19. A process for the production of alcs. such as EtOH comprises bringing a mixt. of an olefin such as C_2H_4 and water vapor at a temp. between 150° and 325° and under superatm. pressure into contact with a catalyst comprising a porous supporting material such a silica gel impregnated with phosphotungstic acid or other heteropoly acid, the complex ion of which includes an element of group VI, sub-group A of the periodic table, the reaction being carried out in the presence of an inert gas such as CO_2.

Unsaturated alcohols. I. G. Farbenindustrie A.-G. Brit. 508,062, June 20, 1939. Alcs. contg. acetylenic linkages are prepd. by bringing aldehydes or ketones into contact with C_2H_2 hydrocarbons of the formula RC:CH, R being H or the radical of a hydrocarbon, in the presence of Cu, Ag, Au or Hg or a compd. thereof, particularly their C_2H_2 compds. Agents capable of binding acids, e. g., formates, acetates, carbonates, bicarbonates or hydroxides of alkali or alk. earth metals or Mg, ZnO, $ZnCO_3$ or alkali metal phosphates or silicates, may also be present. The absorption of C_2H_2 is favored by the addn. of substances having large surfaces, e. g., kieselguhr, silica gel or active C, which may be impregnated with a soln. of the heavy metal salts. Examples are given of the prepn. of 1,4-butynediol and propargyl alc. from CH_2O, 1,4-dimethyl-2-butyne-1,4-diol and 3-butyn-2-ol from AcH, 1-phenyl-2-propyn-1-ol from BzH, 1,4-tetramethyl-2-butyne-1,4-diol and 2-methyl-3-butyn-2-ol from Me_2CO, etc.

Dehydrogenating alcohols. Rudolph L. Hasche (to Eastman Kodak Co.). U. S. 2,173,111, Sept. 19. Reactions such as the production of propionaldehyde and propionic acid from PrOH are effected by heating the alc. to about 275–300° and bringing it into contact with a dehydrogenating catalyst which has a low tendency to dust and which comprises water-quenched pellets obtained from blown cuprous oxide maintained at a slightly higher temp. than the preheating temp. Various details of app. and operation are described.

Aldehydes. I. G. Farbenind. A.-G. (Otto Schmidt, Karl Huttner and Georg Käb, inventors). Ger. 679,257, Aug. 1, 1939 (Cl. 12*o*. 7.03). Addn. to 660,735 (*C. A.* **32**, 6666[7]). High-mol. unsatd. aldehydes are prepd. by passing formic acid and unsatd. carboxylic acids contg. at least 10 C atoms over a catalyst at below 1/20 atm. pressure. Thus, formic and oleic acids, together with CO_2 are passed over a catalyst of pumice impregnated with $Mn(NO_3)_2$ to give olealdehyde.

Indole aldehydes. I. G. Farbenindustrie A.-G. and Wilfred W. Groves. Brit. 506,797, June 1, 1939. Addn. to 438,278 (*C. A.* **30**, 2577[5]). To introduce an aldehyde group, indoles contg. (a) in the 2-position an alkyl group having not more than 3 C atoms or an aryl group and which is unsubstituted in the 3-position but may or may not be substituted at the N atom, or (b) a substituent at the N atom, a reactive CH_2 group in the 2-position and 2 alkyl groups in the 3-position are caused to react with a condensation product of $COCl_2$ and a *N*-formyl compd. of a secondary aromatic amine. The $COCl_2$ condensation products may be made by introducing $COCl_2$ into a soln. of the formyl compd. in a solvent, e. g., toluene, PhCl, CCl_4, dichloroethylene. In an example, $COCl_2$ is introduced into a C_6H_6 soln. of *N*-methylformanilide and 1,3,3-trimethyl-2-methyleneindoline is then added drop by drop; 1,3,3-trimethyl-2-methyleneindoline-ω-aldehyde is obtained by adding alkali to the product and distg.

Aldehydes, ketones and alcohols. I. G. Farbenindustrie A.-G. Brit. 506,850, June 6, 1939. See Fr. 832,072 (*C. A.* **33**, 2534[3]).

Aldehydes, ketones and alcohols. I. G. Farbenindustrie A.-G. Brit. 507,204, June 7, 1939. Aldehydes or ketones of high mol. wt. are obtained by the condensing action of a secondary amine or a salt thereof on (a) an aldehyde contg. a reactive CH_2 or CH_3 group, or a mixt. of such aldehydes with 1 another or with other aldehydes, or (b) a mixt. contg. an aldehyde of any kind and a ketone contg. a reactive CH_2 or CH_3 group, the reaction being effected under such conditions that the H_2O formed is continuously removed. Among examples, (1) crotonaldehyde is condensed in the presence of morpholine acetate and the H_2O formed is removed by azeotropic distn. with the aid of C_6H_6; a mixt. of unsatd. aldehydes contg. 8 C atoms or more is obtained and is hydrogenated in octyl alc. in the presence of a Ni catalyst; the products include dodecyl and cetyl alcs., and (2) a mixt. of cyclohexanone and BzH is condensed in the presence of piperidine acetate and the H_2O formed is removed by azeotropic distn. with toluene, 2,6-dibenzylidenecyclohexanone being obtained.

Polymeric α-halovinyl methyl ketones. Lothar W. Metzger and Otto Bayer (to I. G. Farbenind. A.-G.). U. S. 2,173,066, Sept. 12. Polymeric α-chloro- or α-bromovinyl methyl ketones are produced from the corresponding monomeric compds. even on standing and are suitable for use as intermediates for various reactions.

Isobutenylamines. Miroslav W. Tamele and Herbert P. A. Groll (to Shell Development Co.). U. S. 2,172,822, Sept. 12. A process for the production of isobutenylamines involves treating isobutenyl chloride with more than an equiv. quantity of NH_3 or an amine in the presence of *sec*-Bu alc. at a temp. of about 80–250° under a superatm. pressure at least equal to the combined vapor pressures of the constituents of the reaction mixt. at the operating temp. Details are given of the production of isobutenylamine, b. about 78°, diisobutenylamine, b. about 149°, triisobutenylamine, b. about 194–5°, isobutenylphenylamine, b_{10} about 105–6°, *N*,*N*′-diisobutenylethylenediamine, b_{10} 91.8–94.8°, isobutenylcrotylamine and diisobutenylcrotylamine; and general mention is made of reacting materials for the production of numerous other products by similar reactions.

Separating aromatic amines from pasty reduction mixtures derived from nitro compounds. Harold G. Mow (to National Aniline and Chemical Co.). U. S. 2,174,008, Sept. 26. An arrangement of app. is described, and a method of sepg. an aromatic amine (such as aniline or *m*-phenylenediamine or α-naphthylamine) from a pasty mixt. also contg. Fe oxide as formed by reducing a nitroaromatic compd. with Fe in the presence of aq. $FeCl_2$, which involves heating the mixt. at an abs. pressure below 10 in. Hg in a rotary mill to distil off the amine and simultaneously subjecting the mixt. to the action of freely movable, ponderous agitators, such as balls of Fe or steel.

Diamidines. May & Baker Ltd., Arthur J. Ewins, Harry J. Barber, George Newbery, Julius N. Ashley and Alan D. H. Self. Brit. 507,565, June 12, 1939. Diamidines are prepd. from dicyano compds. of formula NCRXRCN, where each R is a C_6H_6 nucleus and X is a simple linkage or a group $(CH_2)_n$ wherein *n* is 1–12 and 1 or more of the CH_2 groups may be replaced by O or S or by NH. The dicyano compds. are treated in soln. in an anhyd. aliphatic alc. with dry HCl or HBr, optionally in the presence of an addnl. solvent, whereby the corresponding imino ether hydrohalides are obtained; the latter are then converted into amidines by reaction with NH_3, optionally in alc. soln. Among examples, diamidines are prepd. from (1) 4,4′-dicyanodiphenylmethane, prepd. from 4,4′-diaminodiphenylmethane by the Sandmeyer reaction, (2) 4,4′-dicyanodiphenyl sulfide, prepd. from 4,4′-diaminodiphenyl sulfide, (3) 4,4′-dicyano-α,β-di-

phenoxyethane, prepd. by condensing *p*-hydroxybenzonitrile (I) with ethylene dibromide, and (4) *p,p'*-dicyano-1,5-diphenoxypentane, prepd. from I and pentamethylene dibromide.

Amino glycols. Henry B. Hass and Byron M. Vanderbilt (to Purdue Research Foundation). U. S. 2,174,242, Sept. 26. 2-Amino-2-ethyl-1,3-propanediol, m. about 38°, 2-amino-2-propyl-1,3-propanediol, m. 58°, and 2-amino-2-isopropyl-1,3-propanediol, m. 74° (solns. of which are suitable *for absorbing CO_2 and H_2S from industrial gases*) are prepd. by reduction or catalytic hydrogenation of the corresponding nitro compds. Various details of procedure are given.

Crotonic acid esters. The Distillers Co. Ltd. and Hanns Peter Staudinger. Brit. 507,778, June 21, 1939. Esters of crotonic acid with aliphatic, cycloaliphatic and aromatic alcs., e. g., BuOH, glycerol, glycol, cyclohexanol, benzyl alc. (II), are made by causing crotonaldehyde (I), alc. and O to react in the presence of a nonacidic oxidizing catalyst, e. g., Mn crotonate or phosphate, Cu crotonate. In an example, I, II, C_6H_6, MnO_2 and H_3PO_4 are heated in a flask and air is introduced, H_2O being carried away by the C_6H_6.

Polyglycol esters of fatty acids. Lever Brothers & Unilever Ltd. and Reginald Furness. Ger. 679,971, Aug. 17, 1939 (Cl. 12*o*. 11). Crude esters contg. unesterified OH groups and free glycerol or polyglycerol are heated to 80–100° with an aq. soln. of an inorg. salt such as Na_2SO_4 to form a polyglycerol ester. In the example a crude ester from coconut oil contg. 23% ester and 77% unesterified polyglycerol is heated with an aq. soln. of Na_2SO_4.

Cyclic formals. I. G. Farbenindustrie A.-G. Brit. 507,571, June 14, 1939. These are prepd. by causing 1 mol. of an aliphatic monoolefin, e. g., C_3H_6, C_4H_8 or C_5H_{10}, to react with preferably about 2 mols. of CH_2O or its equiv. of a substance that yields CH_2O) in the presence of a strong mineral acid or a metal salt thereof having an acid reaction or an org. acid derived from a strong mineral acid, e. g., $ZnCl_2$, HCl, H_2SO_4, $KHSO_4$, H_3PO_4, phosphotungstic acid or benzene- or toluenesulfonic acid. Aq. CH_2O may be used. An indifferent org. solvent may be employed. Among examples, (1) $ZnCl_2$ soln., paraformaldehyde, C_3H_6 and methylene chloride are caused to react at 120° for 12 hrs. under pressure, the resulting butylene glycol formal being sepd. by fractional distn.; and (2) trimethylethylene, aq. CH_2O and concd HCl are refluxed for 10 min. to produce the trimethylbutylene glycol formal.

Quaternary ammonium bases. Heinrich Ulrich and Ernst Ploetz (to I. G. Farbenind. A.-G.). U. S. 2,173,069, Sept. 12. For the production of a quaternary NH_4 compd., an alkylene oxide such as ethylene oxide is treated with triethanolamine or other tertiary amine of the general formula $R_1N(R_2)R_3$, where R_1 stands for a hydroxy lower alkyl group, and R_2 and R_3 are from the class consisting of aliphatic hydrocarbon radicals, hydroxy lower alkyl, cycloalkyl and aralkyl groups, and aliphatic radicals which, together with the N atom, form a heterocyclic ring, in an aq. medium the pH of which is between about 8 and about 9 at the beginning of the reaction. Numerous examples are given. Cf. *C. A.* **33**, 1961[9].

Unsaturated carbonyl compounds. N. V. de Bataafsche Petroleum Maatschappij. Brit. 508,435, June 30, 1939. Carbinol-contg. carbonyl compds. are dehydrated to the corresponding unsatd. carbonyl compds. by distn. in the presence of a dehydrating catalyst, H_2O being added to the still head or distn. column to form an azeotrope. The unsatd. carbonyl compd. is drawn off as top product. Thus, diacetone alc. is converted to mesityl oxide, 2,6-dimethyl-3-hepten-4-on-6-ol and triacetone alc. to phorone, propionoin to ethyl propenyl ketone, acetobutyl alc. to 4-hexen-2-one, hydracetal acetone to ethylidene acetone, hexane-2,5-dion-3-ol to 3-hexene-2,5-dione, 2,5-chloral acetone to trichloroethylidene acetone, 2,5-dimethylolcyclohexanone to 2,5-dimethylenecyclohexanone, α-hydroxyethyl phenyl ketone to acrylylbenzene, etc. Catalysts used are alkali metal acid sulfates, I, HCl, tungstic acid, H_2SO_4, H_3PO_4, $(COOH)_2$, ZnO, Al_2O_3, Cr oxide, phosphates of Al and Na, $ZnCl_2$, $CaCl_2$.

Separation and purification of carbonyl compounds. Karl Miescher and Werner Fischer (to Soc. pour l'ind. chim. à Bâle). U. S. 2,172,590, Sept. 12. A process for the sepn. and purification of homologous satd. and unsatd. carbonyl compds. obtainable by the side-chain degradation of steroids by reaction with carbonyl reagents contg., in addn. to the group capable of condensing with the carbonyl group, a group selected from the class consisting of a salt-forming group and a group capable of conversion into a salt-forming group, sepn. and subsequent decompn. of the condensation products, comprises causing the mixt. of the homologous carbonyl compds. to react with the carbonyl reagents and decompg. the condensation products obtained, carrying out at least one of these steps partially.

Acetylacetic acid derivatives. Anthony H. Gleason (to Standard Oil Development Co.). U. S. 2,174,239, Sept. 26. For making an acetylacetic acid deriv. such as methyluracil, diketene is treated with urea or with a hydroxy amine, and during the reaction undesirable side reactions are inhibited by preventing undue rise of temp. (the temp. of the reacting materials suitably being maintained below about 80–100°).

Anthraquinone derivatives. Henry C. Olpin. Brit. 507,065, June 7, 1939. Leuco-1-amino-4-hydroxyanthraquinones are made by acting with NH_3 on leuco-1,4-dihydroxyanthraquinones free from amino groups and discontinuing the reaction before any substantial proportion of the corresponding 1,4-diaminoanthraquinone is produced. The reaction may be effected in presence of H_2O or an org. liquid. The leuco compd. first obtained may be oxidized by free O in presence of pyridine or piperidine, with H_2SO_4 with or without $PhNO_2$, or with substantially anhyd. H_2SO_4 according to Brit. 501,341 (*C. A.* **33**, 5871[6]). In an example, leucoquinizarin is treated with aq.-alc. NH_3, followed by oxidation with 96% H_2SO_4, with or without $PhNO_2$.

Anthraquinone compounds. Henry C. Olpin and Charles F. Topham. Brit. 507,206, June 8, 1939. Leuco-1,4-di(monosubstituted-amino)anthraquinones, in which the substituents in the 2 amino groups differ, are made by causing to react with 2 different primary amines together or in succession a leuco-1-amino-4-hydroxyanthraquinone in the form of the reaction mixt. in which it has been prepd. by the action of NH_3 on a 1,4-dihydroxyanthraquinone free from amino substituents, the NH_3 having been used in excess of that theoretically required to replace 1 OH group by an NH_2 group (cf. Brit. 507,065 (preceding abstr.)). The leuco compds. so obtained may be oxidized to the parent materials. In an example, leucoquinizarin is caused to react with excess NH_3 in EtOH to give 1,4-aminohydroxyanthraquinone which is then treated without isolation with a mixt. of NH_2Me soln. and monoethanolamine to give leuco-1-methylamino-4-hydroxyethylaminoanthraquinone, which is oxidized by adding $CuSO_4$ and pyridine and blowing in air.

Guanidine derivative. Chemische Fabrik von Heyden A.-G. (Rudolf Gebauer, inventor). Ger. 679,972, Aug. 17, 1939 (Cl. 12*o*. 17.04). Addn. to 665,510 (*C. A.* **33**, 1104[6]). Pure di-*p*-phenetyl(6-ethoxy-3-pyridyl)-guanidine (I) is prepd. by sepg. it from a mixt. with triphenetylguanidine (II) by using the different degrees of soly. of their HCl salts. Thus, di-*p*-phenetylthiourea and 2-ethoxy-5-aminopyridine are heated to boiling in CCl_4. The resulting mixt. of the I and II is sepd. by treatment with concd. HCl. The di-salt crystallizes out, leaving the tri-salt in soln. The HCl salt of the I m. 183°.

Methylene ether derivatives of xylosonic acid. F. Hoffmann-La Roche & Co. A.-G. (Tadeus Reichstein and Roger Prince, inventors). Ger. 679,975, Aug. 18, 1939 (Cl. 12*q*. 24). Methylene ether derivs. of *d*-xylosonic acid or its salts or esters are prepd. by oxidizing a monomethylene ether deriv. of *d*-xyloketose, in alk. soln. at the lowest possible temp. to convert a primary OH group into a COOH group, and sepg. the resulting acid or ester. Thus, monoacetone-*d*-xyloketose is dissolved in dil. KOH

and treated with $K_2Mn_2O_8$ to give 2,3-monoacetone-*d*-xylosonic acid, m. 264 5°.

Naphthylamine derivatives. Imperial Chemical Industries Ltd Brit. 506,928, June 6, 1939. β-Naphthylamine (I) or tetrahydro-I is hydrogenated at 250-300° under a pressure eventually not less than 2000 lb. per sq. in. in the presence of a catalyst contg. Ni and in the presence or absence of an inert solvent to produce decahydro-I or bis(decahydro-β-naphthyl)amine.

Naphthalene derivative. I. G. Farbenind. A.-G. (Alfred Riecke and Walter Rudolph, inventors). Ger. 679,340, Aug. 3, 1939 (Cl. 12*p*. 10). Addn. to 659,881 (*C. A.* **32**, 7058[9]). 8-Amino-2-naphthol unsubstituted in the NH_2 group is heated with a dehydrogenating agent to give dehydrobinaphthalenediimine. Examples are given.

Naphthalene derivatives. I. G. Farbenind. A.-G. (Werner Zerweck and Wilhelm Kunze, inventor). Ger. 679,977, Aug. 11, 1939 (Cl. 12*q*. 33). 4-Hydroxy-1-aminonaphthalene-8-carboxylic acid or 4-hydroxynaphthostyril is prepd. by coupling 5-naphthol-1-carboxylic acid with a diazo compd. and reducing the resulting monoazo compd. Thus, *p*-toluidine is diazotized and coupled with 5-naphthol-1-carboxylic acid in alk. soln. The product is reduced by $Na_2S_2O_4$ to give 4-hydroxy-1-ammonaphthalene-8-carboxylic acid. By treating this with HCl, 4-hydroxynaphthostyril is formed.

Complex metal amine salts. Frederick C. Bersworth (to Martin Dennis Co.). U. S. 2,173,823, Sept. 26. Complex metal amine salts such as those *for use in tanning* or *electroplating processes* are produced by a method which involves the reaction together of a hydrocarbon halide such as ethylene dichloride, NH_4OH and a hydroxide of a metal capable of forming a Werner complex such as that of Cr.

Alkyl halides. Friedrich Rothweiler (to I. G. Farbenind. A.-G.). U. S. 2,172,568, Sept. 12. See Ger. 664,321 (*C. A.* **33**, 645[1]).

Alkyl bromides. David J. Pye and Harry H. Purcell (to Dow Chemical Co.). U. S. 2,173,133, Sept. 19. For the production of an alkyl bromide such as MeBr, a satd. aliphatic alc. such as MeOH is heated with Br and SO_2 in the presence of sufficient water to dil. the H_2SO_3 produced so that sulfation of the alc. is substantially avoided. An arrangement of app. is described.

Guanidine nitrate. Robert Burns, Peter F. Gay and Imperial Chemical Industries Ltd. Brit. 507,498, June 15, 1939. This is prepd. by the interaction of NH_4NO_3 and a cyanamide salt in the presence of a proportion of H_2O not less than 4%, calcd. on the wt. of NH_4NO_3.

Crystalline basic phenylmercury nitrate. Josef Kathöl (to Schering-Kahlbaum A.-G.). U. S. 2,173,845, Sept. 26. A method of producing a cryst. basic nitrate of hydroxymercuribenzene of the general formula $(C_6H_5)_2Hg_2(ONO_2)(OH)$, comprising the step of isolating the same from aq. HNO_3 solns. of crude prepns. obtained on producing nitrates of hydroxymercuribenzene. Isolation may be effected by cooling to effect pptn.

Ring closure of aromatic compounds with use of hydrofluoric acid. Wm. S. Calcott, John M. Tinker and Adrian L. Linch (to E. I. du Pont de Nemours & Co.). U. S. 2,174,718, Sept. 26. Ring closure such as in the production of anthrone from diphenylmethane-2-carboxylic acid is effected with use of a proportion of concd. HF sufficient to leave an acid residue of not less than 43% HF strength after the ring closure. Numerous examples with details are given.

Glycolic acid. E. I. du Pont de Nemours & Co. Brit. 508,383, June 29, 1939. See U. S. 2,153,064 (*C. A.* **33**, 5006[4]).

Sulfonic acids. Chemische Fabrik R. Baumheier Kom.-Ges. (Rudolf Kern, inventor). Ger. 678,134, July 8, 1939 (Cl. 12*o*. 23.01). Addn. to 663,983 (*C. A.* **33**, 280[9]). The process of 663,983 for prepg. nuclear-substituted fatty aromatic sulfonic acids is modified by carrying out the reaction at 40-75°. Thus a mixt. of tetrahydronaphthalene, benzyl chloride, castor oil, BuOH and $H_2SO_4.H_2O$ is heated to 45-50° to give a product useful as a *washing and foaming agent*. Other examples are given.

Acid anhydrides. Horace F. Oxley and Edward B. Thomas. Brit. 507,592, June 19, 1939. These are made by introducing the vapor of a lower anhydride, e. g., Ac_2O, below the surface of a liquid higher acid maintained in the liquid phase (if desired by means of solvent) and allowing the vapor of the lower acid to escape. The process may be applied to the production of anhydrides of propionic, *n*- and iso-butyric, caproic, caprylic, capric and myristic acids, acids contg. aromatic groups, e. g., BzOH, phenylacetic and naphthoic acids, unsatd. acids such as oleic and cinnamic acids and polycarboxylic acids such as succinic acid.

Ethylene. I. G. Farbenindustrie A.-G. Brit. 506,832, June 6, 1939. See U. S. 2,154,676 (*C. A.* **33**, 5416[9]).

Olefins. I. G. Farbenindustrie A.-G. Brit. 507,567, June, 13, 1939. Gaseous olefins are obtained from the products of the catalytic hydrogenation of CO, the constituents of which contain more than 1 C atom and may or may not contain O, by leading them at elevated temp. with H over a hydrogenation catalyst and cracking and/or dehydrogenating the resulting hydrocarbons. The initial products may be led with H at 180-200° and ordinary or elevated pressure over metals of groups 6 to 8 or their compds., e. g., Ni, on carriers. The subsequent cracking is effected in known manner, e. g., at above 700°, with use of app. that inhibits C deposition, e. g., comprising coatings of Si or Ti or Cr steels as described in Brit. 403,647 (*C. A.* **28**, 3414[9]) and 469,101 (*C. A.* **32**, 4758[8]). The products may be sepd.; liquid products are returned to the hydrogenation or constituents boiling at 80-120°, mainly aromatic hydrocarbons, are removed. Gaseous products may be treated to remove acetylenic compds., olefins then being sepd. with ammoniacal cuprous salts. C_2H_4 may be sepd. by pressure distn. and the higher olefins hydrogenated as described in Brit. 506,832 (preceding abstr.) and wholly or in part subjected to cracking or dehydrogenation. In an example, an oil obtained from CO and H is hydrogenated at 200° and 180 atm. with use of a Ni-Al catalyst and led with cracking gas through a packed tube of Cr steel at 750°, a gas contg. C_2H_4 35, higher olefins 20, H 10, CH_4 30, CH_4 homologs 5% and an oil contg. C_6H_6 hydrocarbons being obtained.

Ethylene from hydrocarbons such as those of gas oil. Donald A. Rogers (to Solvay Process Co.). U. S. 2,174,196, Sept. 26. App. is described, and a process for the manuf. of C_2H_4 from hydrocarbons of higher mol. wt. by a cyclic regenerative process of thermal cracking in the presence of steam wherein heat of hot combustion gases is supplied to a cracking zone in one period of a cycle and steam and hydrocarbon to be cracked are supplied to the zone in another period of the cycle and cracked therein to form a reaction mixt. at a temp. between 780° and 1050°, which comprises passing air into contact with hot refractory A to heat the air and cool the refractory, burning a fuel with the heated air to form hot combustion gases, passing the hot combustion gases into contact with refractory B to heat the refractory to at least the cracking temp. of the hydrocarbon to be cracked and cool the gases, and removing the cooled combustion gases apart from products of cracking, in the one period, and in the other period passing steam and hydrocarbon into contact with refractory B to heat the steam and hydrocarbon to the cracking temp. of the hydrocarbon to be cracked, passing the resultant mixt. into contact with refractory A to transfer the heat absorbed from refractory B to refractory A and thereby cool the products of cracking, and recovering the cooled products apart from combustion gases.

Dehydrating ethanol. Alan Marples (to Carbide and Carbon Chemicals Corp.). U. S. 2,173,692, Sept. 19. An arrangement of app. is described, and a process for dehydrating aq. EtOH which comprises distg. it in the presence of diisopropyl ether; removing from the distg. app. a vaporous three-component mixt. consisting of ether, alc., and less water than is contained in the ternary azeotropic mixt. of these substances; condensing and sepg. the mixt. into an upper ether layer and a lower water layer; returning the ether layer as reflux to the

column, substantially no other reflux being employed; and recovering substantially anhyd. alc. as a still bottom.

Diethyl ether. Pape & Co. G. m. b. H. Ger. 679,970, Aug. 17, 1939 (Cl. 12*o*. 5.09). In making Et_2SO_4 by treating EtOH with dil. H_2SO_4, the acid sludge from mineral oil refining processes may be used as the dil. H_2SO_4. An example is given.

Vinyl methyl ketone. I. G. Farbenindustrie A.-G. Brit. 508,080, June 23, 1939. This is prepd. continuously from vinylacetylene (I) and H_2O in the presence of a catalyst by causing a liquid contg. the catalyst and I to flow in circuit in countercurrent, e. g., in a countercurrent trickling app., during which operation vinyl methyl ketone and steam are continuously withdrawn and a new quantity of catalyst and H_2O is continuously added, while part of the catalyst together with resinous polymerizate formed is continuously removed. App. is described. Cf. *C. A.* **33**, 7822[4].

Separating divinylacetylene and ethynylbutadiene. Albert S. Carter (to E. I. duPont de Nemours & Co.). U. S. 2,173,272, Sept. 19. An aq. H_2SO_4 soln. of $HgSO_4$ is used for removing assocd. ethynylbutadiene from divinylacetylene (suitably with fractional distn. following steam distn.).

Thiourea. Richard O. Roblin, Jr. (to American Cyanamid Co.). U. S. 2,173,067, Sept. 12. A cyclic method for the manuf. of crystals of thiourea involves synthesizing thiourea in the presence of a soln. of thiourea, cooling the liquid reaction product to a temp. sufficiently low to "drop out" crystals of thiourea, sepg. such crystals from mother liquor, and returning the mother liquor to the cycle. An arrangement of app. is described, and the process may involve adding H_2SO_3 to a reaction slurry formed from Ca cyanamide and H_2S under 1.5–2 atm. pressure and at a temp. of 70–80°.

Treating benzene with chlorine and sulfur dioxide, and similar reactions. Cortes F. Reed (50% to Charles L. Horn). U. S. 2,174,111, Sept. 26. By bubbling Cl and SO_2 through benzene in suitable proportions, at a temp. of 0–20°, there is produced *p*-chlorobenzene chlorosulfite; at 20–70°, a mixt. of this product and *p*-dichlorobenzene; and above 70°, polymerization products; and analagous reactions are effected by use of SeO_2 or TeO_2 instead of SO_2 and by use of other halogens instead of Cl.

Diphenylamine. Société des usines chimiques Rhone Poulenc and Igor Scriabine. Brit. 507,860, June 22, 1939. Diphenylamine is prepd. by causing PhCl or an alkali benzenesulfonate to react with $PhNH_2$ in the presence of caustic alkali and removing the eliminated H_2O as fast as it is formed. The presence of a small quantity of Cu and (or) CuO and (or) Cu salt favors the reaction.

***l*-Piperitone.** Howards & Sons Ltd., John W. Blagden and Walter E. Huggett. Brit. 508,001, June 26, 1939. This is isolated from crude mixts. thereof with piperitone racemate by causing it to crystallize from a solvent at below −40°. The solvent may comprise the nonketonic substances present in the crude starting material, or may be a liquid of low f. p., e. g., petroleum ether, which is added before the cooling operation or in a cooled condition after that operation.

Tripropionin and other esters. Lester W. A. Meyer and Frederick R. Conklin (to Eastman Kodak Co.). U. S. 2,173,124, Sept. 19. A process for treating a lower aliphatic acid with a higher alc. having a higher b. p. than the acid, to produce an org. ester having a higher b. p. than the acid, comprises treating alc. with a 75–300% excess of a lower aliphatic acid, distg. water and a substantial amt. of acid from the reaction mixt. during the reaction period, whereby the degree of esterification is increased, condensing the distillate, refluxing a portion of the condensate to the reaction mixt. at a predetd. rate, decreasing the rate of reflux as the esterification reaction proceeds to completion, and then subjecting the reaction mixt. after substantially all the water has been removed to a distn. treatment under reduced pressure to remove any unreacted acid. Numerous examples are given.

1,4,5,8-Tetraminoanthraquinone. Société Rhodiaceta Brit. 507,302, June 13, 1939. See Fr. 831,229 (*C. A.* **33**, 2542[5]).

Butadiene. I. G. Farbenindustrie A.-G. Brit. 507,847, June 20, 1939. Butadiene is produced by heating dimethyl- or ethylacetylene with basic oxides or hydroxides or alkali salts having an alk. reaction, e. g., alkali and alk. earth oxides and hydroxides, Al_2O_3, bauxite, ZnO and alkali carbonates, phosphates and silicates, or mixts. thereof. The walls of the reaction chamber may be coated with alkalies or alk. earths. Diluents are preferably present. Among examples, ethylacetylene is led at 460° and 35 mm. through MgO.

Styrene and alkylstyrenes. The Distillers Co. Ltd., Herbert M. Stanley and John B. Dymock. Brit. 507,984, June 23, 1939. Addn. to 495,023 (*C. A.* **33**, 2622[9]). Styrene (I) and (or) a nuclear alkyl deriv., or derivs., of I are sepd. from a mixt. thereof with an α-alkylstyrene and (or) a nuclear alkyl deriv., or derivs., thereof (other than a mixt. of I and α-methyl-I) by subjecting the mixt. to the action of concd. H_2SO_4 at ordinary temp., whereby substantially only the compds. contg. an α-alkyl substituent are polymerized, and sepg. the polymerized substance from the unpolymerized substances. Among examples, a mixt. of *p*-isopropyl-I (II), α-methyl-II and a residue of *p*-diisopropylbenzene (III), such as may be obtained by the noncatalytic pyrolysis of III, is agitated with 70% H_2SO_4, the II and the III being then fractionally distd. from the viscous oily polymer of the α-methyl-II.

A.* **33**, 2543[4]. — Addnl. data and discussion. During glucolysis much 3-glyceraldehydephosphoric forms, then changes (reversibly) to dihydroxyacetonephosphoric acid. At equil. about 1.1% of the total triosephosphoric acid is in the aldehyde form. L. E. Gilson

Porphyrins in biology and pathology. V. Formation of porphyrins by yeast poisoned with sulfonal. J. Thomas. *Bull. soc. chim. biol.* **21**, 1033–8 (1939); cf. *C. A.* **33**, 998[9]. — Sulfonal, trional, barbital and C_6H_6 increased the formation of coproporphyrin by beer yeast; acetanilide, amidopyrine and phenylhydrazine did not. L. E. Gilson

Activation and inhibition of cholinesterase. L. Massart and R. Dufait. *Bull. soc. chim. biol.* **21**, 1039 (1939); cf. *C. A.* **33**, 8643[8]. — The action of cholinesterase was largely but not completely inhibited by Na oxalate, citrate, fluoride, arsenite and pyrophosphate in 0.02 *M* concns. NaSCN and NaCN had no inhibiting action. When horse serum was dialyzed against dil. $NaHCO_3$ soln. 40% of the cholinesterase activity was lost, but was restored by addn. of ionic Ca, Mg or Mn. Sr had a slight

reactivating action, Ba and Cd had no action, and Co and Cu caused a further loss of activity. L. E. Gilson

Incorporation (in vitro) of fat acids in phospholipides of intestinal mucosa. Richard H. Barnes, Elmer S. Miller and Geo. O. Burr. *Proc. Soc. Exptl. Biol. Med.* **42**, 45–7 (1939). An emulsion contg. bile acids, pancreatic lipase, water and tagged fat (cf. *C. A.* **33**, 8652[6]) was injected into the duodenum in live rats. After 15 min. allowed for absorption, the small intestine was removed, washed, allowed to stand *in vitro* at room temp. 2–6 hrs., then frozen dried and extd. A small fraction of the tagged fat acids was found in the form of phospholipides in the ext. L. E. Gilson

Precipitation of insulin with rhodamine-B. H. Gershberg and J. C. Forbes. *Proc. Soc. Exptl. Biol. Med.* **42**, 95–6(1939).—The dye rhodamine-B ppts. insulin from aq. soln. at pH 7.2. The ppt. is sol. in very dil. HCl. Very little of the hypoglucemic activity is lost. L. E. G.

Proteolytic enzymes and the question of protein storage. U. S. Ashworth. *Proc. Soc. Exptl. Biol. Med.* **42**, 145–6 (1939). The arginase activity of the liver, the tryptic activity of the pancreas and presumably the activity of the other proteolytic enzymes of the rat body are gradually lowered during protein starvation. This would account for the continued drop in the endogenous N excretion and would support the hypothesis that there is no strictly min. level of N excretion. L. E. Gilson

Acceleration of hemolysis in relation to chemical structure. II. The straight-chain alcohols. Eric Ponder and Chester Hyman. *Proc. Soc. Exptl. Biol. Med.* **42**, 320–2(1939); cf. *C. A.* **33**, 6364[6]. For the primary alcs. contg. 3–9 C atoms there is a logarithmic relation between the no. of C atoms and the power to accelerate the hemolytic action of very dil. saponin solns. L. E. Gilson

Dopa decarboxylase. P. Holtz *Naturwissenschaften* **27**, 725(1939). The kidney and liver of many animals contain an enzyme which decarboxylates dihydroxyphenylalanine (dopa) to hydroxytyramine (*C. A.* **33**, 8629[8]); it also occurs in the small intestine of guinea pigs and is preformed in the fetal organs. Its reactions include increase in blood pressure by the hydroxytyramine, which can be amplified by cocaine, splitting off of CO_2 in Warburg app. during amine formation, isolation and identification of hydroxytyramine as Bz compd. For a guinea-pig kidney content of 100%, pig kidney contains 75%, in equal amts. of tissue, rabbit kidney 25–20%. With 2 cc. phosphate ext. from guinea-pig kidney (1:5) 2 mg. dopa is converted quantitatively in 30 min. Only *l*-dopa is attacked. In the presence of O_2 the reaction yields dihydroxyphenylacetaldehyde owing to the presence of aminoxidase. The aldehyde lowers the blood pressure. The complete system decarboxylase + aminoxidase is a *l*-amino acid desaminase. Oxidative demolition of the amino acid is prevented by octyl alc., HCN inhibits the decarboxylase, if the first part of the reaction takes place without O_2 the second part will follow even in the presence of HCN. The *d*-dopa, not occurring in nature, is attacked by the system like other artificial amino acids: it is decompd. by the *d*-amino acid desaminase of organ exts. in the presence of HCN or octyl alc. Guinea-pig kidney has little of the *d*-enzyme, rat kidney has no decarboxylase but ample *d*-desaminase; other individual differences for different animals are found. Dopa decarboxylase is nonidentical with histidine or tyrosine decarboxylase (*C. A.* **32**, 3466[9], 3470[3], 7545[6,8]; **33**, 5420[8]), as shown by adsorption behavior: the tyrosine decarboxylase is adsorbed on kaolin, the others are not. Rabbit kidney has as much histidine decarboxylase as guinea-pig kidney but 1/4 as much dopa decarboxylase. By successive decarboxylation, oxidation and methylation conversion from dihydroxy-phenylalanine to adrenaline is possible and this is considered important for the adrenaline formation in the organism. B. J. C. van der Hoeven

Glucosone as a substrate for glyoxalase. P. G. Efendi and A. P. Ryzhova. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 335–8(1939)(in German).—Fresh aq. exts. of rabbit liver (20 ml. of ext. dild. 1:5 with H_2O) in phosphate buffer at pH 6 were treated at 37° with varying amts. of glucosone (I) to det. whether glyoxalase (II) has a specific action toward substances of the general type RCOCHO. The solns. were then treated with 2,4-$(NO_2)_2C_6H_3NHNH_2$ after removal of protein to det. the unconverted I. II was inactive if more than 1.5 mg. of I/cc. of ext.-buffer soln. was used. In concns. of 0.5–1.0 mg. of I/cc. a slow decrease in I was observed in 4–6 hrs., while the control of 0.5 mg./cc. of methylglyoxal (III) showed a 40% decrease in III in 30 min. The addn. of 0.2–0.3 mg./cc. of reduced glutathione (IV) increased the rate of I decompn. The coenzyme activity of IV was specific. The end products of the reaction are gluconic and mannonic acids. S. A. K.

Variations in the active reaction of the blood and cerebrospinal fluid as a result of the irradiation of the brains of dogs with ultra-short waves. V. Efimov and R. Rutberg. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 388–91(1939)(in French).—The application of ultra-short waves to the brain of a dog for 30 min. caused a reduction in the pH of the blood and cerebrospinal fluid which appeared 2–3 hrs. after irradiation, reached a min. of 7.15–7.17 in 12–24 hrs. and returned to the normal of 7.35–7.46 in 36–48 hrs. S. A. Karjala

The chemical nature of anticatalase. I. The relation between the action of anticatalase of animal tissues and their content of reducing substances. A. Charikova. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 418–51(1939)(in French).—Amts. of EtOH and AcH of 1:10,000, and the thermostable philocatalase destroy the inhibiting properties of anticatalase (I) toward catalase (II), and to some extent restore activity to inactivated II. I is not an enzyme, is thermostable and is not dialyzable. No relationship was observed between I and the amt. of reducing substances (calcd. as glutathione (III)) in the tissues. A slight parallelism between I and the oxidized III in the tissues was noted. S. A. Karjala

Enzymic action of nucleotide-like substances. I Tetutaro Tadokoro and Naomoto Takasugi. *J. Agr. Chem. Soc. Japan* **15**, 876–8(1939). Pyridine nucleotide prepd. from yeast had a strong ascorbic acid oxidase action. Catalase action was observed in pyridine nucleotide, guanylic acid and adenylic acid. Pyridine nucleotide also had a strong peroxidase action and its optimum pH was 5.4. Inosinic acid showed no enzyme action. Y. Kihara

Enzymes in rice malt. Hirohisa Munakata. *J. Agr. Chem. Soc. Japan* **15**, 891–902(1939). The actions of amylase, α-glucosidase, β-glucosidase, sucrase, pectinase, protease, glycerophosphatase, phytase, lipase, lecithinase, esterase, catalase, peroxidase, oxygenase and urease were demonstrated in germinated rice. Tannase and reductase was absent. Especially the activities of glycerophosphatase, phytase and catalase were noted. Protease consisted of the pepsin or papain type having the optimum pH at 3.0–4.2, the trypsin type having the optimum pH at 6.8–7.0, the erepsin type at 8.0–8.5, and another type having the optimum pH at 7.0–7.5. Y. Kihara

Separation of phosphatases into protein and prosthetic groups. I. Separation of alkaline kidney phosphatase D. Albers. *Z. physiol. Chem.* **261**, 43–54(1939).—By dialysis of a phosphatase soln. from kidney (*C. A.* **29**, 3693[6]) the enzyme is sepd. into apoenzyme (nondialyzable) (I) and coenzyme (dialyses). Combining the 2 produces activity of 96% of the original compared to 8% in I alone. Mg^{++} is an addnl. factor in activating the holoenzyme formed from I and II and not as previously believed the sole dialyzable activator or coenzyme. Milton Levy

Specificity of sweet almond emulsin preparations variously manufactured. Wm. W. Pigman. *Z. physiol. Chem.* **261**, 82–6(1939); cf. *C. A.* **33**, 7826[8].—Relative activities of sweet almond prepns. to phenol glucosides were detd. The prepns. were the untreated ext., ext. treated with C, Ag-purified, Ag-purified, C-treated and tannin-purified. The last shows a relatively greater α-mannosidase activity than the others, indicating the independence of this activity and the β-glucosidase activity. Milton Levy

The physiological role of enzymes. N. M. Sisakyan. *Bull. acad. sci. U. R. S. S., Sér. biol.* **1939**, 33–42(in

English, 42).—Review and discussion of reversible enzymic processes in plant tissues with 45 references. J. Livak

Nicotinic acid amide and cozymase in the blood. Hans v. Euler and Fritz Schlenk. *Klin. Wochschr.* **18**, 1109–11 (1939).—A summary of analytical methods for the detn. of these substances and of the amts. present in blood, tissues and excreta. H. L. Mason

The presence of glycerophosphatase in human feces. L. Koster. *Acta Med. Scand.* **101**, 482–90(1939); cf. *C. A.* **33**, 2915[4].—Method: Rub about 5 g. fresh stool in a mortar with 10–15 cc. physiol. saline to a homogeneous mass. Transfer to a flask and make up the total vol. of saline exactly to 25 cc. Shake for an hr. and filter. Measure 0.2 cc. filtrate into a 5-cc. tube contg. 2 cc. barbital-glycerophosphate buffer pH 8.6, and incubate for 1 hr. A second similar tube, contg. in addn. 1.8 cc. 10% CCl_3CO_2H, serves as control. After incubation add 1.8 cc. 10% CCl_3CO_2H to the first tube. Pipet from each tube 1.5 cc. into small test tubes and treat with 1.2 cc. molybdic reagent and 0.3 cc. $SnCl_2$ The color developed in 15 sec. (max.) is compared in a colorimeter. Human feces were found to contain a glycerophosphatase which is activated by Mg ions from the food. The enzyme may be influenced by administered drugs. In nontropical sprue the enzyme content is diminished or may be lacking On the contrary, in myeloid leucemia high values are found. S. Morgulis

Chondroitinsulfuric acid, heparin, albuminuria, amyloid and serum proteins. M. Ch. Ehrström: *Acta Med Scand.* **101**, 551–65(1939). -No causal relation was found between albuminuria and chondroitinsulfuric acid. A mixt. of human serum and the Ca salt of mucoitinsulfuric acid was kept sterile for 2 months. On drying, a substance was obtained which resembled amyloid in some respects. It is also pointed out that the presence of chondroitinsulfuric acid in serum may so alter the pptn. of the proteins that one may even get an apparent hyperglobulinemia. Both chondroitinsulfuric acid and heparin, added to blood *in vitro*, cause a pos. formaldehyde-gel reaction, increase in sedimentation rate, pos. Takata-Ara reaction, increased viscosity and coagulability at relatively lower temp. These results, however, do not prove yet that similar effects are produced *in vivo*. S. Morgulis

Magnetic properties of the compounds ethylisocyanide-ferrohemoglobin and imidazole-ferrihemoglobin. Charles D. Russell and Linus Pauling. *Proc. Natl. Acad. Sci. U. S.* **25**, 517-22(1939). -Et isocyanide combines easily with ferrohemoglobin to give a compd. with an absorption spectrum consisting of 2 narrow bands, at about 5540 and 5250 A. Ethylisocyanide-ferrohemoglobin is completely diamagnetic, and accordingly contains no electrons with unpaired spins. The substance is shown to have the ratio isocyanide to heme iron equal to unity. It is probable that the isocyanide mol. connects the Fe and C atoms. Imidazole combines with ferrihemoglobin to form a compd. with spectrum differing little from that of ferrihemoglobin hydroxide. Data from magnetic titrations at pH 6.86, 8.20 and 10.30 can be interpreted on the assumption of the simple equil. $HHbIm^+ \rightleftarrows HHb^+ + Im$ in which the symbol HHb^+ is used to represent the ferrihemoglobin cation. The values found at 25° for the equil. const. $K = (HHb^+)(Im)/(HHbIm^+)$ are the following: at pH 6.86, 2.5×10^{-3}; pH 8.2, 2.0×10^{-3}; pH 10.3, 0.31×10^{-3}. The bonds to Fe in the imidazole-ferrihemoglobin mol. are of the octahedral covalent type. W. J. Peterson

Distribution of astaxanthin in the animal and plant kingdom. Richard Kuhn, Jörgine Stene and Nils Andreas Sörensen. *Ber.* **72B**, 1688–701(1939).—A table is given showing all sources, ranging from green algae to birds, from which cryst. astacin (I), m. 228° (cf. *C. A.* **32**, 9053[6]), has been isolated. Especially noteworthy is its occurrence in the green alga, *Hematococcus pluvialis* (II), for it has hitherto been generally regarded as an animal pigment. The euglena rhodone (III) isolated by Tischer (*C. A.* **33**, 6361[9]) from the spores of II and which he considered to be 4,6,4′,6′-tetraketo-β-carotene, isomeric with I, agrees in cryst. form and all other properties with I, but he states that it forms no phenazine with o-$C_6H_4(NH_2)_2$. Using the same material and procedure the authors obtained his ester A (IV), which with alcoholate in a high vacuum gave a blue-black soln. immediately changing to red in air; the course of the changes, as regards time and color, was exactly like that of lobster astaxanthin (V), m. 216°, and its fat acid esters. As III itself, like I, gives no such color reaction but forms an orange-red K salt, it is evident the native IV cannot be an ester of a tetraketone. This made T.'s structure for III questionable, for no autoxidizable tetraenol corresponding to V can be derived from a 4,6,4′,6′-tetraketone. The carotenoid obtained by alk. sapon. of IV was identical in all respects with the I from lobsters and gave with o-$C_6H_4(NH_2)_2$ the known phenazine, m. 222-3°. Debye-Scherrer pictures of the 2 pigments likewise showed no differences. T. regarded IV, which m. 100–1°, as a dipalmitate, but the synthetic dipalmitate of V m. 72°. As a matter of fact, IV is a *mono ester;* analysis, catalytic hydrogenation and colorimetric mol.-wt. detns. indicate the acid residue contains 16 C atoms and 1 double bond. The synthetic *monopalmitate* of V m. 113.5-14.5° (cor.). Ester C was obtained in cryst. form, m. 34–6°, and proved to be a diester of V, probably with the same acid as in IV. Brockmann and Völker (*C. A.* **28**, 4454[2]) isolated I from the "roses" of pheasants. The authors, avoiding alk. sapon., found that here, too, V and its esters are present exclusively. The food of the pheasant, both wild and in various zoos, is known quite exactly and contains no V, indicating that the pheasant is capable of synthesizing it from other carotenoids. Wald and Zussmann (*C. A.* **31**, 7103[8]) were able to obtain I, with other carotenoids, from the retina of chickens. The opinion already expressed that this was an artefact has been confirmed. The pigment isolated without the use of alkali gave with alcoholate the color reaction of V. Chromatographic analysis on sucrose showed the retina of the hen contains at least 2 different esters of V. V was obtained in 23.6-mg. yield from a liver (1080 g.) of *Regalecus glesne*. The synthetic *dipalmitate* of I m. 121°; the name *astacein* for the supposed dipalmitate in the lobster (Karrer, Loewe and Hübner, *C. A.* **29**, 2544[1]) is now superfluous. C. A. R.

Isocitric acid dehydrogenase and glutamic acid synthesis in higher plants and in yeast. Hans v. Euler, Erich Adler, Gunnar Günther and Larissa Elliot. *Enzymologia* **6**, 337–41(1939)(in German).—Higher plants and yeast contain a coenzyme II-specific dehydrogenase for isocitric acid. The reaction catalyzed by this enzyme is activated by Mn and Mg ions. The enzyme corresponds completely to the isocitric acid dehydrogenase previously isolated from animal tissues. The glutamic acid dehydrogenase of higher plants acts specifically with coenzyme I, thereby differing from the animal dehydrogenase which acts with either coenzyme I or coenzyme II, and the dehydrogenases from yeast and *B. coli* which act only with coenzyme II. Felix Saunders

Specificity and field of action of the phosphatase of the sweet almond. II. Action of some chemical compounds on the hydrolysis of different substrates. Jean Courtois and Jacqueline Manouvrier. *Enzymologia* **6**, 342–51 (1939)(in French); cf. *C. A.* **33**, 6883[4], 8644[8].—The hydrolysis of the Me, Pr and Bu monoorthophosphates by the phosphatase of the sweet almond is weakly inhibited by Mg and NaF. Fe, Cu and Ca salts do not affect the enzyme nor does dialysis. The hydrolysis of these esters or β-glycerophosphate is not affected by ascorbic acid. Ascorbic acid oxidized by methylene blue or by $Fe(NO_3)_3$ has little or no effect on the phosphatase. Oxidation of the phosphatase by I causes a definite but weak inhibition. Ascorbic acid oxidized by Cu salts strongly inhibits. All the substrates behave the same way toward the inhibitors. Bu phosphate is the most sensitive. In the lowest concns. the phosphatase of the type A_3 of takadiastase is activated by ascorbic acid. At other concns. it is inhibited by the acid oxidized by I and $CuSO_4$ but not when oxidized by methylene blue. Felix Saunders

Blockage and the transfer of reducing hydrogen. I. Reducing hydrogen of dichlorophenolindophenol. L. Genevois and P. Cayrol. *Enzymologia* **6**, 352–74(1939)

(in French). —The transfer of the reducing H of SH derivs. or hydrazines to dehydroascorbic acid or alloxan can be brought about by means of blockage reactions. The transfer is remarkably rapid. It is completed by a small excess of the reducing substance. Glutathione is an indispensable protector of ascorbic acid in tissues. Glutathione cannot be replaced by cysteine which is too sensitive to ketones. The concn. of the glutathione must be at least 3 times that of the ascorbic acid, a condition which is realized *in vivo*. Felix Saunders

Kinetics of the formation of chymotrypsin from crystalline chymotrypsinogen and of trypsin from crystalline trypsinogen. M. Kunitz. *Enzymologia* **7**, 1-20(1939)(in English); cf. *C. A.* **33**, 2153⁹. Chymotrypsinogen is transformed into chymotrypsin by means of minute amts. of trypsin but not by enterokinase or chymotrypsin. The formation of chymotrypsin by means of trypsin follows the course of a unimol. catalytic reaction. Trypsin is formed from trypsinogen by trypsin itself in the range of pH 5.0-8.0 and by mold kinase at pH 2.5-4.0. The transformation of trypsinogen into trypsin by means of either trypsin, or enterokinase at pH above 6.0 is accompanied by the transformation of a part of the trypsinogen by means of the trypsin formed into an inert protein which cannot be changed into trypsin. The formation of trypsin from trypsinogen by means of mold kinase at pH 3.0 or by means of enterokinase in the range of pH 5.0-6.0 follows the course of a catalytic unimol. reaction just like the process of formation of chymotrypsin by means of trypsin. The process of formation of trypsin by means of trypsin is essentially autocatalytic in character. The kinetics of the reaction is, however, complicated by the secondary catalytic reaction, namely the formation of inert protein. The formation of trypsin by means of enterokinase at pH above 6.0 is greatly affected by the complication due to the partial transformation of the trypsinogen into inert protein, the more so the lower the concn. of enterokinase used. As a result, the ultimate amt. of trypsin formed is less as the concn. of enterokinase used is decreased. Felix Saunders

Stearic specificity of glutamic acid dehydrogenase. Hans v. Euler and Erich Adler. *Enzymologia* **7**, 21-4 (1939)(in German). Irradiation of an enzyme prepn. from liver decreases somewhat the activity toward *l*(+)-glutamic acid and still more the activity toward *d*(−)-glutamic acid. Irradiation of a mixt. of substrate and apodehydrogenase or *d*(−)-glutamate alone had no effect on the reaction velocity. Felix Saunders

Enzymic deamination of amino acids and its physiological significance. A. E. Braunshtein. *Enzymologia* **7**, 25-52(1939)(in German); cf. *C. A.* **33**, 5015⁹. The specificity, possible reaction mechanisms and physiol. significance of deamination are discussed. The prepn. of 2 new enzymes which deaminize glutamic acid and asparagine, resp., is described. These enzymes, known as *aminopherases*, differ from previously known enzymes concerned with amino acid metabolism. F. Saunders

Tributyric esterase activity of plasma and red blood cells. Effect of citric and oxalic acids, hydrogen-ion concentration and amount of blood used. G. Scoz. *Enzymologia* **7**, 82-7(1939)(in Italian). Oxalic acid and citric acid increase the activity of the lipases of red cells and blood plasma by about 400%. Both lipases work best at pH 8. The erythrocyte lipase is much more sensitive than the plasma lipase to pH changes. The relation between the amt. of blood plasma and its lipolytic power (p) can be expressed by the equations $p = K \log E$ and $p = K\sqrt{E}$, where E is the amt. of enzyme. For the red cells the equation $p = KE$ holds. Felix Saunders

Existence of a lipase in the suprarenal gland of the ox. G. Scoz and B. Mariani. *Enzymologia* **7**, 88-96(1939)(in Italian).—The cortex of the suprarenal gland of the ox has a tributyric lipase activity. It will hydrolyze tributyrin but not olive oil. The medulla has a true lipase activity. Both activities have their optimum at pH 9.3. Their activity is inhibited by quinine, atoxyl, NaF and chloral hydrate. The activity (p) of these enzymes with respect to time (t) and amt. of enzyme (E) can be expressed by the equations $p = kt$ or $p = kE$. Under certain conditions the equations $p = k \log t$, $p = k \log E$, $p = k\sqrt{t}$ or $p = k\sqrt{E}$ hold. Felix Saunders

Influence of the ultrashort wave irradiation on the growth of rabbit sarcoma. VII. Influence of local irradiation on the entire body of an individual. Noboru Nobuoka. *Gann* **33**, 294-315(1939).—The ultrashort wave irradiation not only retarded the growth of primary Kato rabbit sarcoma in animals, but also inhibited the growth of nonirradiated secondary tumors and the formation of metastases. It requires much more irradiation to kill rabbit sarcoma *in vitro* than *in vivo*. The metabolism of irradiated tumor tissue is greatly reduced as seen by decrease in glucolysis. The 4.5 m. waves had the strongest inhibitory effect upon the tumor growth. K. Sugiura

Experimental studies on the excretion and distribution of radium D, E and F, introduced into the organism, and on their biological action. Mituo Miwa and Hisao Yamasita. *Gann* **32**, 395-431(1938).—About 100 mc. of radon was kept sealed in a glass tube with 20 cc. of distd. water and was allowed to change into Ra D, E and F. The soln. was injected intravenously into adult rabbits in 20-120-cc. amts., in single or divided doses. In young albino rats, 1.0-5.0 cc. was injected intravenously. Rabbits showed a slight decrease in body wt., but no diarrhea. In young rats, it caused a marked disturbance in nutrition or even death. Ra D was excreted in the urine very rapidly and in the feces less rapidly. Blood examn. showed a marked decrease in the no. of both red and white cells, but especially of lymphocytes. Among the changes in the internal organs, atrophy of the spleen, lymph nodes and thymus was most striking. Although the injected Ra D, E and F are excreted, some remained in the body for a fairly long time, the amt. retained varying in different organs. K. Sugiura

Condensation of the hexapeptide ester of glycine into the 96- and higher (3×2^n) peptide esters. Eugene Pacsu. *Nature* **144**, 551(1939). The condensation by heat of the hexapeptide ester of glycine gives 12-, 24-, 48- and other peptide esters, the no. of glycine mols. being expressed by the general formula 3×2^n. The condensation at 102° goes through a series of bimol. reactions with 10^4 $K = 150$ and has an activation energy of 38 kg.-cal. Neither "cyclol 6" nor nonapeptide is formed in the reaction. The substances are suggestive of denatured protein and give a strong biuret reaction. E. D. Walter

Catalase. R. Lemberg, M. Norrie and J. W. Legge. *Nature* **144**, 551-2(1939). Catalase contains 1 bile pigment hematin group, similar to verdohematin, in addn. to 3 protohematin groups. By splitting with acids, biliverdin is isolated from cryst. catalase. Evidence is given to support the view that the bile pigment hematin is an essential part of the enzyme mol. E. D. Walter

Decomposition of hydrogen peroxide by catalase. Frank H. Johnson and K. L. van Schouwenburg. *Nature* **144**, 634-5(1939). An app. and procedure are described whereby H_2O_2 was decompd. by catalase under anaerobic conditions. Attention is directed to the use of luminous bacteria as a means of detecting the presence of O_2. E. D. Walter

Galactose-1-phosphoric acid in galactose metabolism. H. W. Kosterlitz. *Nature* **144**, 635-6(1939); cf. *C. A.* **33**, 8176⁴. The role of galactose-1-phosphoric acid as an intermediate in the metabolism of galactose in liver and in yeast is discussed. This ester is fermented by dried galactose-adapted *S. cerevisiae* Frohberg at approx. the same rate as glucose, while galactose is fermented very slowly. The metabolism of galactose in the liver differs from fermentation by dried yeast in that galactose-1-phosphoric acid accumulates in the liver. E. D. Walter

Inactivation of tyrosinase in the oxidation of pyrocatechol. B. J. Ludwig and J. M. Nelson. *J. Am. Chem. Soc.* **61**, 2601-6(1939).—It has been found when tyrosinase (I) from *Psalliota campestris* is inactivated in the oxidation of pyrocatechol (II) that the inactivation at 25° involves a const. uptake of O: 100 ± 5 cu. mm. per unit of enzyme or 3.3

$\times 10^4$ cu. mm. per γ of Cu. This amt. of O is independent of the rate of oxidation of the II, the concn. of O, the H-ion concn. between pH 5 and 7.5 or the ratio of catecholase (III) activity to cresolase activity but is dependent on temp. The inactivation is not due to any products known to be formed in the oxidation of the II but occurs at the time the II is oxidized. I from different sources consumes different amts. of O per unit of III inactivated. The total O consumed in the inactivation of purified prepns. from *Lactarius piperatus* at 25° is 400 ± 15 cu. mm. per unit or 1.7×10^4 cu. mm. per γ of Cu. Hydroquinone, when used in excess with low concn. of II, besides serving as a reductant for o-benzoquinone (IV), exerts a protective influence against inactivation of the enzyme. Ascorbic acid, also a reductant toward IV, exerts no protective influence. BzOH exerts a retarding influence on the activity of I toward II but has no protective action.

C. J. West

Tyrosinase from the wild mushroom, Lactarius piperatus. H. R. Dalton and J. M. Nelson. *J. Am. Chem. Soc.* **61**, 2946–50(1939).—A method is described for prepg. highly purified prepns. of tyrosinase (I) from *Lactarius piperatus*. I is shown to be a Cu protein; the purest prepn. contained 0.23% Cu and had a dry wt. of 1 mg. per 1000 cresolase units and 0.0027 γ of Cu per cresolase unit. The Fe present in the crude prepns. of I can be removed by adsorption methods. Purified I prepns. showed no definite absorption bands in the visible region of the spectrum, differing in this respect from the hemocyanins; 2 absorption bands were observed in the ultraviolet region: a band due to protein at 273 mμ and one at about 330 mμ probably due to Cu. A cryst. material was obtained, from rather crude as well as from purified prepns. of I, having a Cu content of 0.25% and 13.6% N; these crystals were colorless and belonged to the isometric system; the av. size was about 0.01 mm. Solns. of the crystals were only slightly active toward *p*-cresol and catechol. This slight activity showed a tendency to increase when the solns. were permitted to stand for some time. Certain solns. of the freshly prepd. I also showed this tendency to increase in activity on standing. The ratio of activities of the I prepns. toward *p*-cresol and catechol could not be altered by various methods of purification but always remained 10 to 1, resp. The ratio of the 2 activities in the case of the solns. of the cryst. material was also 10 to 1. Compn., similarly in absorption spectra, the slight increase in activity when solns. are allowed to stand, all point to a close relationship between the crystals and the highly purified I prepns.

C. J. West

Molecular weight and association of the enzyme urease. David B. Hand. *J. Am. Chem. Soc.* **61**, 3180–3(1939).—From the osmotic pressure the av. particle wt. of cryst. urease solns. is found to be 700,000. From the rate of diffusion, particles with a wt. as low as 17,000 are shown to possess urease activity. There is no evidence to show in which form urease exists at the time that it exerts its catalytic action.

B—METHODS AND APPARATUS

GLENN E. CULLEN

Vitamin K. Methods for determination of thrombin of the blood. K. K. Nygaard. *Nord. Med.* **4**, 3372–3 (1939).—A brief survey is given of methods for detn. of thrombin of the blood in connection with vitamin K treatment.

V. Aschehoug

Estimation of ammonia in feces. Adolfo E. Raices. *Rev. méd.-quir. patol. femenina* **14**, 881–8(1939).—The ammonia contained in 10 cc. of an aq. suspension of feces (5%) should be distd. by steam for 7–10 min. into a tube contg. 3 cc. of 0.1 *N* HCl. Add 1 cc. of 10% NaOH to the suspension and liquid paraffin to avoid foaming. Det. the ammonia colorimetrically after nesslerization.

E. S. G. Barron

Detection of alkaloids in animals by spectroscopic analysis of saliva. Ramon G. Loyarte and Jacinto Placeres. *Roentgen* **1**, No. 7, 12 pp.(1938).—To detect the presence of alkaloids in horses injected with small amts. (as in horse races), the ultraviolet absorption spectrum of saliva is recommended. Place the saliva in 96% alc.; centrifuge it for 20 min. at 3000 r. p. m. Evap. the filtrate in the water bath at 60°, adding small amts. of water up to 10 cc. of fluid. Filter, washing the filter 3 times with hot water; evap. to dryness at 60°; dissolve with 10 cc. abs. alc. which is reduced to 5 cc. in the water bath; filter; wash the evapg. dish and filter twice with 1 cc. warm abs. alc.; dry at low temp.; dissolve in 1% AcOH; filter, evap. to dryness at 60°; dissolve in alc. Cocaine and morphine can be detected in the spectrograms when the horse has received an injection of 0.1 g. Caffeine can be detected after a 1-g. injection; strychnine after a 0.004-g. injection.

E. S. G. Barron

Determination of cholinesterase and its potential significance. H. M. Eberhard and W. S. Silverman. *Rev. Gastroenterol.* **6**, 239(1939).—0.5 cc. of serum is incubated with 150 mg. acetylcholine bromide. The AcOH formed is titrated with 0.01 *N* NaOH.

E. Borek

Application of the Proteus test to the determination in the urine of nicotinic acid and its derivatives. C. Lataste. *Bull. soc. path. exotique* **32**, 784–91(1939).—A modification of the method of Lwoff, Querido and Lataste (cf. *C. A.* **33**, 6379[1]) was used. The daily excretion of free nicotinic acid or amide in the urine of normal man was 0.5–1 mg. After hydrolysis of the urine for 3 hrs. at 130° or at room temp. for many days, 3–5 mg. was found. The *Proteus* test is specific for nicotinic acid or amide and its hydrolyzable derivs. in the urine.

E. Curzon

Ascorbic acid determinations on tissues by the dichlorophenolindophenol and methylene blue methods. A. Giroud, E. Géro, M. Rabinowicz and E. Hartmann. *Bull. soc. chim. biol.* **21**, 1021–32(1939); cf. *C. A.* **33**, 7359[5].—Results of detns. by both methods are given for all the important tissues of the steer and guinea pig. In all cases the methylene blue method gave slightly lower values.

L. E. Gilson

Microtechnical demonstration of phosphatase in tissue sections. G. Gomori. *Proc. Soc. Exptl. Biol. Med.* **42**, 23–6(1939).—A fixing and staining method of showing the presence or absence of phosphatase in the individual cells is described.

L. E. Gilson

Isolation of glutathione from thymus glands. Norwood K. Schaffer and Wm. M. Ziegler. *Proc. Soc. Exptl. Biol. Med.* **42**, 93–4(1939).—A small amt. was isolated in cryst. form from calf thymus. The method is described.

L. E. Gilson

Separation of lipides in gravimetric acetone method for plasma total protein. Eldon M. Boyd. *Proc. Soc. Exptl. Biol. Med.* **42**, 263–4(1939).—It is suggested that the Bierry and Vivarro method, as outlined in the book by Peters and Van Slyke (cf. *Quant. Clinical Chemistry, C. A.* **26**, 3275), be modified so that 3 cc. plasma is added to 75 cc. Me_2CO instead of 10 cc. in the initial step. When plasma is dild. with 20–25 vols. Me_2CO the Me_2CO ext. contains amts. of lipides identical to those in the EtOH-Et_2O ext. of the same plasma prepd. by Boyd's method (*C. A.* **30**, 4890[1]). Less Me_2CO exts. less lipides.

L. E. Gilson

Thiochrome method for the determination of vitamin B_1. Luigi Callegari. *Boll. soc. ital. biol. sper.* **14**, 487–8 (1939).—In comparing standard aneurine solns. with the unknown (by the Ritsert method (cf. *C. A.* **33**, 7333[8])) it was shown that the best results were obtained when the vols. of the alk. soln. and of the isobutyl alc. soln. were equal and when the NaOH concn. was kept const.

Helen Lee Gruehl

Improved method for the wet ashing of biological materials. M. W. Brenner and P. L. Harris. *Chemist Analyst* **28**, 55–6(1939).—To the weighed sample in a small Kjeldahl flask, add 5 ml. of concd. HNO_3 and heat until brown fumes are evolved. Carefully add 3 ml. of concd. H_2SO_4

and heat until the sample is charred and all excess HNO_3 is removed. Then add 1 2 ml. of 70% $HClO_4$ and heat again. W. T. H.

New and more specific albumin reagent. Jonas Kamlet. *Chemist Analyst* **28**, 62–3(1939).—Dissolve 25 g. com. NH_4 molybdate, 15 g. sulfosalicylic acid and 85 g. citric acid in 1 l. of water. Add 2 ml. of $CHCl_3$ to prevent formation of molds. This reagent will detect 0.005% albumin in urine, and the approx. quantity of albumin can be estd. An Esbach graduated tube adds to the accuracy. W. T. H.

Student apparatus for analysis of respiratory gases. J. Max Little and Herbert S. Wells. *Science* **90**, 425–6 (1939). E. H.

A method for determination of nicotinic acid (pyridine derivatives) in urine. I. G. Porjé. *Nord. Med.* **2**, 1108 10(1939).—The method is based on the reaction of Konig: 5 to 20 cc. urine is dild. with a phosphate buffer (pH = 6.1) to 20 cc. Four cc. satd. aq. soln. of fresh BrCN and 4 cc. satd. aq. soln. of aniline are added. The mixt. is allowed to stand for 7 to 10 min. and the yellow color is then measured in the Pulfrich photometer, screen S 47. If the urine is strongly colored, the detn. can be made by extg. the resulting colored reaction product with AmOH and measuring the color of the ext. In the urine of normal persons 1.2 to 20 mg. nicotinic acid was excreted per day. In the urine of a patient suffering from pellagra, no nicotinic acid could be detected. When 50 mg. nicotinic acid was given (perorally), the output of nicotinic acid in the urine was strongly increased in the following 3 hrs. H. Kringstad

Determination of sulfanilic acid amides Margrethe Hejde Sunesen. *Nord. Med.* **2**, 1663–5(1939). A modification of the method of Marshall and Hecht for detn. of sulfanilic acid amide in blood and urine is described. By injection of sulfanilic acid amide in rats and detn. of sulfanilic acid amide in the body, it was shown that the method yielded good quant. results. H. Kringstad

A method for the determination of blood acetone bodies Richard H. Barnes and Arne N. Wick. *J. Biol. Chem.* **131**, 413–23(1939).—In the method described for the detn. of blood acetone bodies, acetoacetic acid and β-hydroxybutyric acid are oxidized to Me_2CO with H_2SO_4 and $K_2Cr_2O_7$ and the Me_2CO is pptd. as a Hg complex. After centrifuging, the Hg-Me_2CO ppt. is decompd. in HCl and the Me_2CO is distd., collected in alk. I soln. and titrated by the Messinger technique. A. P. Lothrop

Photometric determination of estrogens. I. A modified Kober reaction for determining the total estrogens in a mixture of estrogenic steroids. Carl Bachman. *J. Biol. Chem.* **131**, 455 62(1939); cf. *C. A.* **25**, 5908.—The Kober reaction for the development of colors with estrogenic steroids and phenolsulfonic acid was modified by substituting for the original reagent a dilu. of the sulfonic acid with H_2O and running the reaction at 150° instead of 100°. A mixt. of estrone, α-estradiol and estriol can be accurately detd. under the conditions described. **II. A new color reaction for estriol.** *Ibid.* 463–8. A specific, stable violet-pink color is produced when estriol is heated at 150° with a reagent made up of a soln. of Na *p*-phenolsulfonate in H_3PO_4. A method is described for detg. estriol in the presence of estrone which has been used with pregnancy urine exts. A. P. Lothrop

A new method for the determination of the ether-soluble constituents of the cerebrospinal fluid. Carl Riebeling. *Klin. Wochschr.* **18**, 1162–3(1939).—The substances extd. with ether are oxidized with dichromate-H_2SO_4 mixt. and the excess dichromate is detd. iodometrically. H. L. M.

Studies on blood coagulation. I. Method for the determination of coagulation time. Eugen Hecht. *Acta Med. Scand.* **102**, 79–84(1939).—Description of an app. for detg. coagulation on 5 drops of liquid. The details of the manipulations are discussed. **II. Experiments on the determination of coagulation time.** *Ibid.* 85–100 (1939).—The spontaneous coagulation of chicken plasma (whole or dild. to 75, 50 or 25% with physiol. saline) is delayed according to its diln. and age. It will coagulate even after 7 days but very slowly. However, on the addn. of a drop of embryonal juice fairly rapid coagulation takes place even in plasma 11 days old, the coagulation time varying inversely with the diln. The addn. of 1 drop 8% NaCl greatly increases the coagulation time. The spontaneous coagulation is also delayed through the addn. of $CaCl_2$, the delay becoming longer with increasing concn. Similarly, the spontaneous coagulation proceeds more rapidly with rising temp. within the range of 30° to 40°. The relation between coagulation time and concn. of coagulation activators is formulated mathematically. S. Morgulis

A collaborative investigation of the spectrophotometric method for assay of vitamin A. C. L. Barthe, F. F. Berg, E. B. Carter, D. M. Copley, R. J. Fosbinder, T. Lewis and F. O. Taylor. *J. Am. Pharm. Assoc.* **28**, 661–72 (1939).—In the detn. of vitamin A potency by phys. instruments, the conversion factor is of paramount importance. To achieve the greatest degree of accuracy in results, the E value of the U. S. P. reference oil, its unsaponifiable fraction and (or) any other suitable standard, should be detd. every day and the conversion factor calcd. to check the constancy of conditions necessary for accurate operation of the instrument. In this manner errors due to conditions in the lab., the instrument or the human element can be obviated or at least reduced to a min. Under specified and well-controlled conditions of operation of the phys. instruments, capable of accurate measurement, results can and should be obtained which are in closer agreement than those obtainable by biol. assay. When there is any doubt or question as to the source of the oil under consideration, the optical detn. should be made on the unsaponifiable residue. The suggestion that a spectrophotometric method be adopted as an alternate for the biol. assay is discussed. A. Papineau-Couture

Elimination of diacetyldiaminodiphenylsulfone in the urine. J. Trapl. *Acta Dermato-Venereol.* **20**, 248–56 (1939). A method for finding the presence of diacetyldiaminodiphenylsulfone (I) is reported; it is based on a reaction of the free amino group which, joined with phenol, gives an azo dye. Five cc. of cool acid urine is mixed with 3 grains of $NaNO_2$; after dissolving and shaking with 3 grains of hydroxyquinoline, NaOH is added until the color changes from pink to red. Two hrs. after taking ½ g. of I, its presence could be detected in the urine. Secretion stopped after 24 hrs. Maurice M. Rath

Evaluation of oxalate solutions for the determination of packed cell volume in human blood. Jane M. Leichsenring, Eva G. Donelson, Lucille M. Wall and Margaret A. Ohlsoff. *J. Lab. Clin. Med.* **25**, 35–44(1939).—With all the blood samples (subjects, women, ages 17 to 50 yrs.), 1.6% K oxalate, prepd. from dried salt, was found to be more nearly isotonic, both when the samples were obtained with the subjects under basal and nonbasal conditions, than other salt concns. observed (1.4% and 1.8% K oxalate and 1.2% Na oxalate). Howard W. Robinson

Clinical demonstration of iron in the skin in hemochromatosis. Hamilton R. Fishback. *J. Lab. Clin. Med.* **25**, 98 9(1939). Equal parts of sterile solns. of 0.5% $K_4Fe(CN)_6$ and 0.01 *N* HCl were mixed and injected intradermally so as to form a wheal. A blue color was obtained within 5 min. that disappeared in about 2 weeks. The test is without any evident injurious effects, is specific for hemochromatosis, and is also pos. after death. The neg. test showed a white wheal that disappeared in about the same time. Howard W. Robinson

A ring test for urine bromides. Alex Blumstein, Paul M. Zoll and Jesse J. Mayer. *J. Lab. Clin. Med.* **25**, 99 101(1939).—One cc. of 20% CCl_3COOH soln. is mixed with approx. 5 cc. of urine and the mixt. overlayered with a 0.5% $AuCl_3$ soln. A bromide concn. over 50 mg. % gives a yellow to a reddish orange ring at the interface. Bile and iodides when present in the urine interfere. The test may also be done on spinal fluid and on blood serum after the protein is removed by CCl_3COOH. H. W. R.

Rapid extractor for urinary androgens. Factors to be considered in the preparation of extracts for colorimetric assay. Nathan B. Talbot and George O. Langstroth. *Endocrinology* **25**, 729–36(1939).—A small and convenient

app. which permits extn. of about 90% of urinary androgens in 1 hr. with C_6H_6 is described. Recovery expts. made in part with the aid of this app. show that a significant amt. of androsterone and dehydroisoandrosterone is lost in the prepn. of urine exts. for colorimetric assay. The chief loss occurs when the Et_2O ext. is cleared with decolorizing charcoal. The amt. of androgenic "sterone" substances detd. by the usual colorimetric methods which include treatment with decolorizing charcoal as part of the procedure are not an accurate index of the original "sterone" content of the urine. Felix Saunders

Calibrating Matthes' oxygen meter with alveolar air. Hermann Becker-Freyseng, Ulrich Luft and Erich Opitz. *Luftfahrtmed.* **3**, 30–13 (1939).—Matthes' instrument was calibrated by calcn. of arterial satn. from alveolar O tension and the Henderson nomogram, and also by direct arterial puncture. The former method is inaccurate at very low O tensions. D. B. Dill

Urinary sulfate test in the supervision of workers exposed to benzene (Jephcott, Bulmer) **13**. Studies on the metodetn. of glucose, frye and conjugated glucuronic acid (Kakinuma) **7**.

C—MICROBIOLOGY

LAWRENCE H. JAMES

The chemistry of the lipides of tubercle bacilli. LVIII. Firmly bound lipides of the so-called leprosy bacillus. Walton B. Geiger, Jr., and Rudolph J. Anderson. *J. Biol. Chem.* **131**, 539–48(1939); cf. *C. A.* **26**, 1316; **30**, 4148[8]; **33**, 7337[9].—After exhaustive extn. with alc.-Et_2O the so-called leprosy bacillus contains 19.2% of firmly bound lipides which can be removed by extn. with Et_2O and $CHCl_3$ after the partly defatted cells have been treated with dil. HCl. These extd. lipides can be sepd. into 3 main fractions. The least sol. fraction, which is a white amorphous powder, m. 175–85°, gives 40.5% of carbohydrate and 66.4% of Et_2O-sol. compds. on sapon. The latter compds. are mainly hydroxy acids similar to leprosinic acid but there is also a small amt of lower fatty acids together with unsaponifiable or neutral material contg. *d*-eicosanol-2 and *d*-octadecanol-2. The hydroxy acid is optically active but is apparently a mixt. since no definitely pure acid could be isolated. When heated *in vacuo* to 250 70° the acid decomps. and 15.2% of cryst. acids distil off. From these volatile acids a cryst. tetracosanoic acid, m. 76–7°, having probably a branching chain structure, can be isolated. **LIX. The composition of the polysaccharide of the firmly bound lipides of the leprosy bacillus.** R. J. Anderson and M. M. Creighton. *Ibid.* 549–54.—The polysaccharide of the firmly bound lipides of the leprosy bacillus consists principally of pentosans, *d*-arabinose being the chief constituent together with about 7% of some other pentose or pentoses which could not be identified. A small amt. of *d*-galactose is also present. The sugars isolated account approx. for the total amt. of reducing sugars liberated on complete hydrolysis but represent only about 1/2 of the polysaccharide but the nature of the other nonreducing cleavage products could not be detd. A. P. Lothrop

Metabolic products of *Aspergillus ochraceus* (Yamura) **10**.

THOMAS G. PHILLIPS

Plant viruses. The influence of recent knowledge on methods for their control. Rupert J. Best. *J. Australian Inst. Agr. Sci.* **5**, 162–8(1939).—Recent investigations showing that quite a no. of viruses are proteins may have a marked influence on the search for control measures for virus diseases. J. R. Adams

Vitamin C content of hips. Haakon Natvig. *Tids. Norske Laegeforen.* **59**, 847–60(1939).—Vitamin C was detd. in hips by titration, and biologically. Great variations were found according to the maturity of the hips: Light yellow hips ascorbic acid 1140 mg. %, light red 1668, red 1900, deep red 2200, dark red (overripe) 625, dark red (thin skinned) 440 and dark red to dark 230 (detd. in skin of dried hips). V. Aschehoug

Variation in the vitamin C content of hips of different degrees of maturity. Bergliot Qviller. *Tids. Norske Laegeforen.* **59**, 860–5(1939).—Vitamin C was detd. by titration. The ascorbic acid content increases during maturation and decreases when hips are overripe. *Rosa rugosa* shows higher vitamin C content than *R. glauca* and *R. coriifolia*. V. Aschehoug

Formation of abnormal tissue in chestnut and filbert branches damaged by toxic gas. A. Biraghi. *Boll. staz. patol. vegetale* **18**, 455–70(1938); cf. *C. A.* **33**, 9360[8]; Neger, *C. A.* **14**, 3442.—Near a chem. factory strange growths were observed on the branches of chestnut trees and were ascribed to SO_2 injury. 9 illustrations. **Serious lesions produced on filbert branches by toxic gas.** *Ibid.* 497–508. 6 illustrations. W. F. Bruce

Sulfur content of juice pressed from nondeciduous leaves at different seasons. A. Leulier, L. Revol and L. Tuarze. *Compt. rend. soc. biol.* **132**, 8–9(1939).—Juice pressed from cherry-laurel leaves contained total S in Feb. 49, May 25, June 27.5, July 44, Oct. 47.5, Nov. 47 and Dec. 43 mg. %. Old leaves contain more than young leaves, possibly because they are less hydrated. L. E. Gilson

Remark on the communication of Wergin: Direct observation of 0.2 μ structural elements of the vegetable cell wall. Max Lüdtke. *Naturwissenschaften* **27**, 693–4 (1939); cf. *C. A.* **33**, 1782[8].—Priority claims. **Reply.** W. Wergin. *Ibid.* 694. B. J. C. van der Hoeven

Nutrition experiments with haplonts of Tilletia tritici. Maria Lange-de la Camp. *Kuhn-Arch.* **48**, 179–90 (1939).—A no. of monosporidial lines of *Tilletia tritici* were cultured in a variety of media to det. the influence of nutrition on the intensity, form and color of growth and spore formation. Increasing concns. of rock candy with decreasing peptone was without influence. Optimum growth with peptone was obtained with 1–2%. Changing the pH between 5.9 and 7.0 had little influence on the growth. Dextrose and sucrose proved to be good energy sources; levulose, galactose, maltose and lactose were unsuitable. Inorg. N salts were not utilized. Of the org. N compds., asparagine was the most favorable for growth and spore formation. Nucleic acid, peptone, albumin and casein provided good growth but allantoin was not utilized. C. K. Horner

The course of indicative conditions in the graft propagation of apples. Gerhard Friedrich. *Kuhn-Arch.* **48**, 191–232(1939).—Press juice of the bark and leaves of graft cultivations of several types of apple trees was analyzed for dry matter, monosaccharides, total sugar, osmotic pressure, sol. N and elec. cond. The detns. were made during 6 characteristic growth periods: bud swelling, leaf unfolding, twig development, height of vegetation, autumn leaf fall and winter dormancy. The cultivation on weak growing types resulted generally in greater concns. of sugar and N as well as a higher osmotic value and more dry wt. This did not appear to be due to an obstruction of substances in the graft juncture. The importance of physiol. changes as indicators for the state of development of fruit trees in general is discussed. Sixty-eight references. C. K. Horner

Sclerotium rolfsii Sacc. in the sugar beet. Heinrich Krüger. *Kuhn-Arch.*, **48**, 233–81(1939).—The employed strain of *Sclerotium rolfsii* was isolated in Spain and appears to be identical with numerous other tested strains of this fungus. It attacks not only the sugar beet but wild beets and other Chenopodiacae as well. The organism grows first into the intercellular spaces of the host and later penetrates the cell wall. The destructive agency appears to be due to both an enzymic dissolving factor and a toxic element. Oxalic acid is excreted by the fungus and it combines with the Ca of the cell wall of the host, replacing the normal pectin. The presence of both pectinase and cellulase was demonstrated in cultures of the fungi in nutrient solns. of known chem. constitution. Beet cellulose was more readily attacked than paper cellulose. The organisms do not penetrate collodion membranes. Ni-

trates and NH_3 salts stimulated the development of both sclerotia and mycelium; asparagine and urea favored the latter but depressed the former. As C sources, pectin and cellulose produced the normally observed round form of growth with sclerotia, which occurs under natural conditions. Other carbohydrates (mannitol, dextrin and xylan) allowed good mycelium growth but no sclerotia. The mycelia of germinating fungi were killed at a temp. of −2° to −5° but new mycelia were formed when the cultures were returned to optimum temp. Fifty-six references. C. K. Horner

The influence of the reaction of hydrochloric acid upon the catalase activity in germinated millet seeds. Chi-Chin Liang. *Bull. Chinese Botan. Soc.* **3**, No. 1, 45–52 (1937).—In solns. having pH values greater than 2.9, HCl had no effect on the germination of millet seeds at 22°. At lower values the germination power decreased with the pH and the germinated seeds finally died. There was a close correlation between the catalase activity and the germination power of the seeds, as affected by pH. The catalase activity in distd. water and in HCl solns. of pH 2.9–5.4 tended to increase during the 1st 24 hrs. and the ratio of the activity of treated seeds to that of dry seeds was greater than 1. In the case of seeds treated with HCl solns. having pH values less than 2.9 the ratio rapidly fell below 1. The internal pH of the seeds remained const. at 6.2 when the seeds were soaked for 24 hrs. in solns. having pH values of 2.9–5.4 or in distd. water. The internal pH showed progressive decrease as the pH of the external soln. was decreased below 2.9 and the aq. ext. of the ground seeds lost its colloidal properties. K. D. Jacob

The influence of environmental factors on the development of anthocyanin and the physiological significance of this pigment in Amaranthus cordatus. Chi-Yuen Chia. *Bull. Chinese Botan. Soc.* **3**, No. 1, 119–20 (1937).—A 50% reduction of daylight in the greenhouse caused a considerable decrease in the production of anthocyanin (I) and its formation was completely suppressed under the continuous illumination of a 60-w. Champion lamp. With a 50% reduction of daylight the plant was stimulated to develop I when grown in Knop's nutrient soln. and supplied aseptically with 2% of dextrose. The short wave lengths of the ultraviolet spectrum had no effect on the production of I. Under similar light conditions, induced green plants consumed more O_2 and produced more CO_2 than did normal red plants. Under artificial light, evolution of CO_2 by normal red plants of the same I content increased with the intensity of the illumination. Irradiation of plants with a Hg-vapor lamp caused an increase in the rate of O_2 consumption. K. D. Jacob

The rooting of tung oil tree cuttings with the aid of heteroauxin. Hung-Chang Yin *Bull. Chinese Botan. Soc.* **3**, No. 1, 121–2 (1937).—Formation of roots on tung tree cuttings was greatly increased by soaking the severed ends for 20 hrs. in a soln. contg. 0.2 mg. β-indoleacetic acid per cc. The compd. was slightly injurious at a concn. of 0.4 mg./cc. K. D. Jacob

Fusarium stem rot of the carnation. H. L. White. *Exptl. Research Sta., Turner's Hill, Herts, Ann. Rept.* **24**, 53–5 (1938) (Pub., 1939).—Rooting of carnation cuttings in sand cultures inoculated with spores of *F. culmorum* was not improved by pre-immersion of the severed ends of the cuttings for 15 hrs. in a soln. contg. 40 p. p. m. of α-naphthaleneacetic acid and there was a marked proliferation of the tissues of the stem base assocd. with splitting of the stem and a tendency to rot. Cuttings dipped in a soln. (40 p. p. m.) of a proprietary growth substance showed uniformly good root development and less extensive tissue proliferation and stem splitting and rot. Root development was depressed by watering the planted cuttings with solns. (10 p. p. m. of K) of either KNO_3 or K_2SO_4. K. D. Jacob

Report of the plant physiologist for 1938. F. R. Tubbs. *Tea Research Inst., Ceylon, Bull.* No. 19, 38–56; cf. *C. A.* **31**, 1847[3,4].—No significant effect on the no. of cuttings surviving or the no. rooting in 18 weeks was obtained by immersing the severed ends of tea-bush cuttings for 17 hrs. in a soln. contg. dextrose 2.0 and urea 0.1%. Phenylacetic acid also had no effect on the rooting of tea-bush cuttings and β-indolylacetic acid treatments did not favor the survival, rooting or growth of cuttings of *Camellia sinensis*. K. D. Jacob

Cell-wall constituents of soybeans. II. Chemical constituents of the seed coat. Syuiku Sasaki and Syotaro To. *J. Agr. Chem. Soc. Japan* **15**, 624–8; *Bull. Agr. Chem. Soc. Japan* **15**, 105–6 (1939); cf. *C. A.* **33**, 6903[5].—The seeds consisted of 85–90% embryo and 5–10% seed coat. The analysis of the seed coat was: pectin 17–20, hemicellulose (4% NaOH ext.) 5.6–10.3, crude fiber 51.9, α-cellulose 31.2, β-cellulose 18.2, γ-cellulose 2.5, crude protein 11.7, crude fat 0.96 and ash in dry matter 4.3%. Pectin was prepd. by extn. with 0.5% NH_4 oxalate. The yield was 15–19%. It contained H_2O 2.4, ash 2.7, MeO group 4.7 and uronic acid anhydride 45.5%. Galacturonic acid was found in the hydrolyzate of pectin. Y. Kihara

Growth-factor requirements of four species of isolated roots. James Bonner and Philip S. Devirian. *Am. J. Botany* **26**, 661–5 (1939); cf. *C. A.* **33**, 1784[1] and following abstr.—Isolated pea, radish, flax and tomato roots were cultivated in a mineral nutrient soln. contg. sucrose, vitamin B_1 and nicotinic acid. Addns. of adenine, pantothenic acid, vitamins B_2, B_6, E and K did not increase the growth rate of radish or pea roots. Addns. of β-alanine, ascorbic acid and theelin caused no increase under these conditions in the case of pea roots and asparagine, glutamic acid, glycine, isoleucine, leucine, tryptophan and valine in the case of radish roots. Vitamin B_1 was necessary but nicotinic acid and vitamin B_6 were not needed to cause growth of flax roots. Vitamins B_1 and B_6 were necessary for growth of excised tomato roots and the addn. of nicotinic acid increased the growth rate. Nelson McKaig, Jr.

A second growth factor for excised pea roots: nicotinic acid. Frederick T. Addicott and Philip S. Devirian. *Am. J. Botany* **26**, 667–71 (1939); cf. *C. A.* **33**, 1784[1] and preceding abstr.—Excised pea roots may be grown for an indefinitely large no. of weekly transfers in a soln. contg. only $Ca(NO_3)_2$, $MgSO_4$, KNO_3, KCl, KH_2PO_4, Fe tartrate, sucrose, vitamin B_1 and nicotinic acid. Other elements including pea ash and 20 amino acids singly and in combination could not sustain growth indefinitely in this soln. in absence of nicotinic acid. N. McK., Jr.

Alcohol extraction of growth hormone from plant tissue. Geo. S. Avery, Jr. *Am. J. Botany* **26**, 679–82 (1939).—Growth hormone is extd. from 3-g. portions of corn endosperm or dormant seed by fine grinding in a glass mortar with 15–30 g. of abs. EtOH, followed by filtration and evapn. of the filtrate at 50–55° under reduced pressure. The residue is taken up with water and 1-cc. portions are dild. with 1 cc of hot 3% agar. Further dilns. to bring the concn. of the ext. within the proportionality range are made with 1.5% agar. The final material is cut into blocks and applied to decapitated *Avena* coleoptiles for test by the "deseeded" method. The use of ether in taking up the ext. gives low results and should be avoided. Nelson McKaig, Jr.

A review of the subgenus Diholcos of the genus Astragalus. C. L. Porter. *Am. J. Botany* **26**, 690–3 (1939).—Four species of this Se indicator plant are described. Nelson McKaig, Jr.

Experiments on bud inhibition with 3-indoleacetic acid. Folke Skoog. *Am. J. Botany* **26**, 702–7 (1939).—*Pisum* buds 2.0–3.5 mm. long were grown in a high humidity dark room at 25° in nutrient solns. contg. different amts. of 3-indoleacetic acid (I) to det. whether the inhibition of auxin is direct or indirect. At first all treated plants grew slower than the controls, then plants in lower concns. of I grew as fast or faster than controls. Growth remained inhibited on const. exposure to concns. above 0.1 mg./l. of I. Exposures to 0.1 and 10 mg./l. of I for 65 hrs. stimulated growth after transfer to plain nutrient soln. Applications of 2–4 mg. of I per g. of lanolin to decapitated *Pisum* stems inhibited development of lateral buds for 7 days when applied to the cut surfaces, was 70% effective when applied below the cut surfaces and was ineffec-

tive when applied below the lateral buds. Conclusion: I can inhibit growth directly in buds and I applied to decapitated stems inhibits lateral buds. N. McK., Jr.

Respiration and fermentation in the carrot, Daucus carota. I. Respiration. Paul B. Marsh and David R. Goddard. *Am. J. Botany* **26**, 724–8(1939).—The respiration of carrot root is reversibly inhibited by 10^{-2} – 10^{-5} *M* KCN at pH 5.9 and 10^{-3} *M* NaN_3 at pH 4.5–5.7. Respiration inhibition by CO is reversed by light, indicating that pyrocatechol oxidase is not the enzyme involved. The enzyme which combines with CO has an O affinity 9–13 times its CO affinity. Carrot roots killed by boiling do not consume O but give a pos. Nadi reaction and oxidize a mixt. of *p*-phenylenediamine and catechol. Respiration of immature (less than 3 cm.) carrot leaves is inhibited by NaN_3, HCN and CO but mature (25 cm.) leaves are not affected. Nelson McKaig, Jr.

Response of tomato plants to β-naphthoxyacetic acid. S. C. Bausor. *Am. J. Botany* **26**, 733–6(1939).—Lanolin contg. 1% β-naphthoxyacetic acid causes neg. curvature of tomato stems and petioles below the point of application and pos. curvature in the treated region. A 0.1% paste causes neg. curvature below the point of application and initially in the treated area, which later becomes pos. A 0.01% paste causes a neg. curvature in the treated area only. A 0.001% paste has no effect. Root primordia develop and growth is inhibited after application of 1% and 0.1% pastes. The effects are noticeable within 1 hr. Nelson McKaig, Jr.

Early root and shoot growth in 2 varieties of Avena sativa in relation to growth substances. Samuel Kaiser and Harry G. Albaum. *Am. J. Botany* **26**, 749–54 (1939).—The difference in effect of 3-indoleacetic acid on the varieties Black Norway (I) and Fulghum (II) was studied. Aq. solns. contg. 0.01–5.0 mg./l. of 3-indoleacetic acid showed the same max. inhibition and the same time of max. inhibition at low concns. but was later for II than for I at higher concns. Concns. up to 50 mg./l. increased root growth similarly in the 2 varieties but concns. below 0.002 mg./l. were relatively ineffective. Shoots of I grew rapidly when treated with concns. between 0.002 and 2.0 mg./l., shoots of II were unaffected I was more sensitive to the *Avena* coleoptile test. Apparently II normally produces auxin at a faster rate than I. Nelson McKaig, Jr.

The daily cycle of apparent photosynthesis in a submerged aquatic. Bernard S. Meyer. *Am. J. Botany* **26**, 755–60(1939).—An app. is described for the hourly detn. of apparent photosynthesis of a submerged aquatic without disturbing the plant in any way. The daily curve of apparent photosynthesis is closely correlated with solar radiation, although the frequent skewing of the curves toward the morning hrs. suggests the influence of an internal factor on the course of daily photosynthesis of *Ceratophyllum demersum* L. Nelson McKaig, Jr.

The substances of a green alga which determine sex. Richard Kuhn, Franz Moewus and Gerhard Wendt. *Ber.* **72B**, 1702–7(1939); cf. Hartmann, *et al.*, *C. A.* **33**, 8317⁴.—Along with the gamones active in the process of fertilization proper, gametes secrete still other substances, which det. sex in organisms of mixed sex. In the monozoic culture of *Protosiphon botryoides*, the ratio of male to female cells can be altered by changes in temp. and pH (Moewus, *Biol. Zentr.* **55**, 293(1935)). These phenomena of nonhereditary sex detn. are exhibited even more strikingly in *Chlamydomonas eugametos* f. *synoica* (Moewus, *Biol. Zentr.* **1939** (in press); cf. *C. A.* **33**, 4630⁶·⁸. When the alga is treated with the filtrate of the ♀¹-gametes, all the cells become *female;* if the filtrate of the ♂¹-gametes is added, there are obtained only *male* cells. In this case, changes of temp. or pH are not necessary. These facts show that the gametes secrete sex-detg. substances which are designated *termones* (*andro-* (I) and *gynotermones* (II)). It has not yet been possible to isolate them from the active filtrates, in which their concn. is of the same order of magnitude as that of the motility and coupling gamones. Moreover, to all appearances they have no pigment character. After even long exposure to blue and violet light they can still be detected in undiminished activity long after the coupling gamones have been completely inactivated by conversion into *trans*-crocetin di-Me ester. However, it has been possible to establish that (1) I is sol. in ether and volatile with steam; (2) II cannot be extd. from water with ether and is not volatile with steam; (3) heating with dil. H_2SO_4 or $Ba(OH)_2$ destroys II, and parallel with this inactivation appears the ether-sol. and steam-volatile I. This made it probable that II bears to I the relation of a glucoside to its aglucone. Although the hydrolysis of glucosides by dil. alkalies is unusual, picrocrocin (III) is cleaved to safranal and *d*-glucose. A test of cryst. III, m. 152–3°, from saffron showed that it can replace II. If synoecious cells are placed in a soln. contg. 0.02 γ or more of III in 1 cc. water, in 10 min. all the cells have become capable of coupling with ♂¹-gametes. Again, if 0.1 mg. III in 25 cc. water is treated with 50 cc. of 2% H_2SO_4 or of 3% $Ba(OH)_2$ and steam-distd. at such a rate that 100 cc. distillate passes over in 20 min., neither distillate shows any trace of II activity but both are highly active in I. The limit of activity is reached only when the distillates have been dild. about 10^8-fold. Expts. with safranal prepd. from the purest semicarbazone, m. 174°, with $C_6H_4(CO)_2O$, confirmed these results. As the no. of cells of the alga was 2×10^6 per cc., 10–20 mols. safranal is capable of masculinizing 1 cell. Its action is highly specific; citral, α- and β-cyclocitrals treated in the same way have no effect even in concns. 10^9 times higher, and it is believed that I is safranal. II, however, is not III. When solns. of III and filtrates of ♀¹-cells are adjusted to the same activity in II and then hydrolyzed with dil. H_2SO_4 or $Ba(OH)_2$ the distillate obtained from III is 1000 times higher in I activity. This indicates the filtrate from the cells contains a II 1000 times more powerful than III. The authors believe it to be a substance closely analogous to III, contg. instead of glucose some other sugar, perhaps gentiobiose or a similar disaccharide. The limit of activity of III is at a concn. of 8×10^{12} mols. per cc. and that of a ♀¹-filtrate at 2×10^3 gametes per cc. If II were identical with III this would indicate that each gamete secretes 4×10^9 mols. III. Previous work has shown that under these conditions the gametes secret only 4×10^6 mols. of *cis*- and *trans*-crocetin di-Me esters (crocin). Crocin and III are decompn. products of a carotenoid (protocrocin) with the normal no. of 40 C atoms and the ratio of pigment to bitter principle in fresh saffron is approx. 1:2. In *Chlamydomonas* there would seem, from the above calcns., to be formed 1,000 times as many mols. of II as of crocin; this difficulty is cleared away if it is assumed that II is 1000 times more active than III. The chem. relationship between the fertilization (gamones) and sex-detg. (termones) substances of the alga is shown schematically. C. A. R.

Methods of tissue preparation for analysis in physiological studies with plants. T. C. Broyer. *Botan. Rev.* **5**, 531–45(1939).—A review. Felix Saunders

(Changes in) reducing power of the juice of fruits during the course of maturation. Melle L. Gatet. *Enzymologia* **6**, 375–86(1939)(in French).—The juice of oranges contains free ascorbic acid and ascorbic acid in a form which is easily hydrolyzed in the cold in 8 days. There is also another substance with antiscorbutic properties which will reduce dichlorophenol. The substance may be a form of ascorbic acid which is difficultly hydrolyzable or a polyphenol reducer. Felix Saunders

Spectral sensitivity of spores and sporidia of Ustilago zeae to monochromatic ultraviolet light. Ernest W. Landen. *J. Cellular Comp. Physiol.* **14**, 217–26(1939). Felix Saunders

The influence of phosphoric acid upon the metabolism of young oats plants. W. U. Behrens. *Bodenkunde u. Pflanzenernähr.* **14**, 59–70(1939).—Oats seedlings were started in a P_2O_5-deficient soil or sand and peat, and after a time some pots were top dressed with phosphate. The latter were harvested at 2 later periods with unfertilized pots for comparison and the plants analyzed. Conclusions: P_2O_5 caused an accumulation of total sugar, monosac-

charides and in particular disaccharides. The plants grown with deficient P_2O_5 contained significantly lower percentages of total N, protein and nitrate N in dry matter, but the effect upon amide and α-amino N was uncertain; Et_2O and EtOH-sol. substances were lower. Twenty-two references. C. J. Schollenberger

Development and assimilation of nutrients by flax. K. Opitz. *Bodenkunde u. Pflanzenernahr.* **14**, 172–95 (1939); cf. Opitz, *Forschungsdienst* **1**, 848(1936).—From field and pot expts. with fiber- and oil-flax varieties with analyses of the crop at approx. weekly intervals during the growing season it is concluded: Development of both types of flax is similar up to full bloom; after this stage, oil-flax develops more slowly, owing to the requirements for heavier seed production. Dry matter production by fiber-flax reaches 60%, but the uptake of K_2O is 80% and of N about 70% by blooming time; P_2O_5, CaO and generally MgO are less rapidly assimilated, 60–70% in this period. In the earlier stages of growth, the need for N is greater than for K_2O, although the latter is absorbed more rapidly. Fiber-flax differs principally in forming more dry matter before the assimilation of minerals, except N, has proceeded so far; its need for CaO is less, for K_2O is greater than with oil-flax. The pot and field expts. were in general agreement, and both are considered reliable indications of the plants' need for nutrients at different stages of growth, although differences were less marked with the pot expts.; nutrients were absorbed more slowly and dry matter was produced more rapidly, and there was evidence of greater resorption of minerals with the latter. Considerable losses of K_2O, N and CaO, in magnitude decreasing in that order but dependent upon weather conditions at the time of ripening, were noted in these expts. Twelve references. C. J. Schollenberger

Variations in the potassium content of flax plant ash in the light of the newer biochemical knowledge. Vladimír Kyzlink. *Bodenkunde u. Pflanzenernahr.* **14**, 196–204 (1939); cf. *C. A.* **33**, 7023⁹.—Oil-flax was grown in pots of very poor soil, variously fertilized and limed. Roots, stems with leaves and seeds were ashed separately and K_2O was detd. in a study of the distribution and resorption of K in the plant. Conclusions: Nitrate favors resorption of K_2O and its movement from roots to aerial parts; if the concn. of nitrate N exceeds that of K_2O in the soil soln., seed and stem are equally well supplied with K_2O; if nitrate is deficient relative to K_2O, seeds will contain less K_2O. As observed with other plants, Ca^{++} in the plant tissues is antagonistic to the entrance of K^+; this effect is most marked in the roots, where Ca tends to accumulate at the approach of maturity or from intensive fertilization with nitrate. With an unbalanced fertilization, lacking nitrate, K_2O is high in roots and seeds but low in the stems and leaves, while the latter are higher in CaO; consequently, less K_2O can enter the leaves, and the formation of dry matter is limited. The foregoing observations apply to Ca in the plant; liming a soil is likely to increase the available K_2O by exchange, so that flax stems grown on limed soils are usually higher in K_2O content. Eight references. C. J. Schollenberger

Investigations on the origin of the "zone of root influence" with seedlings of Lupinus luteus. Helmut Schander. *Bodenkunde u. Pflanzenernahr.* **14**, 346–80 (1939); cf. *C. A.* **33**, 2942¹.—The factors which may operate to enable a plant to control the pH of a soil zone adjacent to its active roots and the necessity for such control of root environment are discussed. Expts. are described, from which it is concluded that the problem of root excretions can be solved. A study of the incidence of chlorosis in young lupine plants grown on a plot of soil highly variable with respect to $CaCO_3$ content and pH, including pH and other tests on soil samples taken to several depths at close and regular intervals, so that maps of the soil characteristics both at the surface and beneath might be compared with a similar chlorosis map, showed no striking correlation, possibly because the sampling stations were too widely spaced. It is concluded that pH and salt concn. relations in the root zone are the principal factors in chlorosis, that is to say, along the entire length of all roots; it is not enough that some of the roots are in a favorable environment, but practically all must be. The influence of the subsoil, at least to the full depth of root penetration, 1 m. or more, is therefore, as great as that of the surface soil. Besides the influence of the soil's buffer capacity toward acids, soil structure and water relations also have a role in the tendency to chlorosis. 30 references. C. J. S.

The nitrogen nutrition of Graminea in mixed culture with legumes. Werner Scholz. *Bodenkunde u. Pflanzenernahr.* **15**, 47–73(1939).—In field and sand pot expts., rye with peas or serradella and oats with lupines were grown as mixed crops. The outcome of the field expts. was neg., owing to the soil's naturally abundant supply of available N. The pot expts. with sand showed that the N content of the latter was increased by N excreted from nodules on the legume roots, presumably as amino acids, but grain yields were not thereby increased. Conclusion: The excreted N is immediately utilized by bacteria rather than by the assocd. nonlegume, and benefits ony a following crop. Twenty references. C. J. Schollenberger

Physiological activity of a series of indolyl acids. N. H. Grace. *Can. J. Research* **17**, C, 373–6(1939); cf. *C. A.* **33**, 8697⁸.—The physiol. activity of a series of indolyl acids, from the acetic to the valeric, including 5-methylindolylpropionic, was detd. by the rooting responses of *Lonicera tartarica* cuttings treated with solns. of each. Indolylbutyric acid was the most active chemically, affecting the no. and length of roots per rooted cutting, the mean root length, the green wt. of leaves, and the fresh root wts. Indolylacetic acid had significant effects on the no. and length of roots per rooted cutting. Slight activity was shown by indolylpropionic acid, but neither indolylvaleric acid nor 5-methylindolylpropionic showed any significant treatment effects. None of the acids affected the no. of cuttings rooted. J. W. Shipley

The effect of leaf rust on the yield and quality of Thatcher and Renown wheat in 1938. B. Peturson and Margaret Newton. *Can. J. Research* **17**, C, 380–7(1939).—A study was made at Winnipeg in 1938 to det. the effect of leaf rust on the yield and quality of Thatcher and Renown wheat. In one expt., Thatcher and Renown were sown late in 1/400-acre plots; in another, Thatcher only was used and was sown early in rod-row plots. Half the plots of each variety were kept as free from leaf rust as possible by frequent applications of S dust, but the remaining half became heavily infected. In the 1/400-acre plots, leaf rust reduced the yield of Thatcher and Renown by 51.17 and 29.61%, resp.; in the rod-row plots of Thatcher, it reduced the yield by 37.02%. The decrease in yield was due more to reduction in kernel wt. than to reduction in no. of kernels per head. All the nondusted plots ripened approx. 3 days earlier than the dusted, and the grain from them graded one grade lower than that from the corresponding dusted plots. In both varieties, the protein content was diminished while the carotene content was increased. J. W. Shipley

Identification of the Columbian plant pinic-pinic. Maurice Marie Janot and Ramon Mendoza. *Compt. rend.* **209**, 653–6(1939); cf. Raymond-Hamet, *ibid.* 384.—The pinic-pinic of Columbia is shown botanically, chemically and pharmacodynamically to be identical with the chalchupa of Guatemala, both being *Rauwolfia heterophylla* (Roem. and Schult). Both alike are used by the native inhabitants as antidotes to snake poison and as febrifuges. C. A. Silberrad

A marine Porphyridium. Harald Kylin. *Kgl. Fysiograf. Sällskap. Lund, Forh.* **7**, 119–23(1937)(Pub., 1938) (in German).—A new species *Porphyridium marinum* is described. Spectrographic analyses of alc. and aq. exts. indicate the presence of floridian (not cyanophycean) phycoerythrin, also carotene and xanthophyll. Phylloxanthin is absent. 8 references. **The pigments and the colors of Cyanophyceae.** *Ibid.* 131–58.—A review on chlorophyll, carotenoids, phycoerythrin, phycocyan, cell-wall pigments, regional distribution of Cyanophyceae and complementary chromatic adaptation. Two new species are described. 86 references. **The hydrogen-ion concentration in the vacuoles of some marine algae.** *Ibid.* **8**, 194–204

(1938) (Pub., 1939); cf. *C. A.* **24**, 1406; **32**, 3787[1].—Mainly a review and discussion (with some apparently new data) of the apparent pH of the vacuoles and other structures of a large no. of species of seaweeds investigated by K. and others by the method of vital staining. Brilliant Cresyl Blue (Cresyl Blue) is taken up by the vacuoles more rapidly than is Neutral Red. Mangenot's test for I (formation of red cryst. deposits in the vacuoles by Cresyl Blue) (*C. A.* **23**, 3950) should not be regarded as pos. unless the red crystals liquefy into green flocks when H_2O_2 is added. The use of vital stains in testing for various inorg. ions is discussed. The report by M. Chadefaud (*Le cytoplasme des algues vertes et des algues brunes, ses éléments figurés et ses inclusions.* Thèse, Paris, 1935) that the vacuoles of *Desmarestia viridis* contain oxalate ions, is not confirmed. The crystals obtained by treatment with a soln. of KCl are apparently K_2SO_4. 10 references.

Fucosan vesicles of the Phaeophyceae. *Ibid.*, 205–14.—Evidence regarding the chem. nature of fucosan is critically reviewed. Fucosan is related to the tannins. 33 references. W. C. Tobie

The distribution of anthochlor in the Compositae. Otto Gertz. *Kgl. Fysiograf. Sallskap. Lund, Förh.* **8**, 62–70 (1938) (Pub., 1939) (in German).—Many yellow flowers, especially in the Compositae, contain pigments of the anthochlor (xanthein) group (cf. Klein, *C. A.* **16**, 3110, 4247). These pigments become red in the presence of alkali. Heat also produces a red color; the yellow color is restored by cooling. A convenient test is to touch the flower with the tip of a burning cigar; in this case the color change is [partly] due to NH_3 in the cigar smoke. The color change is obscured if anthocyanin pigments are also present. The test [with alkali?] may be applied to dried flowers; specimens over 300 years old gave a pos. test. The reaction is especially strong in the Coreopsidinae group. Species giving a pos. reaction with NH_3 or KOH are listed in detail (nos. in parentheses below indicate the no. of species tested in each genus): *Guizotia* (6), *Microlecane abyssinica*, *Coreopsis* (49), *Dahlia* (5), *Hidalgoa ternata*, *Inostigma* (4), *Chrysanthellum* (6), *Glossogyne* (2), *Heterospermum* (5), *Thelesperma* (11), *Bidens* (76), *Cosmos* (13). Species giving a neg. or a doubtful reaction are also listed. The results are discussed in relation to other species not classified among the Coreopsidinae but giving pos. reactions. The test is of systematic value, some reclassifications are suggested. 14 references.

The application of anthochlor in botanical microtechnique. The relationship between anthocyanins and anthochlor. *Ibid.* 71–82.—Exts. contg. anthochlor were made by boiling the flowers of *Primula elatior*, *Linaria vulgaris*, *Dahlia variabilis*, *Coreopsis verticillata*, *Guizotia abyssinica*, *Baeria chrysostoma*, *Helenium autumnale*, *Helichrysum arenarium*, *Lotus corniculatus* or *Celosia plumosa* in distd. water and filtering the soln. About 3 drops of H_2SO_4 was added per 10 cc. The exts. were used to stain fresh sections cut from the vegetative portions of 17 widely differing plants and trees. Pb acetate soln. was usually applied after staining to ppt. the pigment as yellow to brown-red granules. In general (with some exceptions) the parts which took the stain were the lignified portions which also stain with phloroglucinol and HCl. Conclusion: Since the same portions of plant tissue also stain with anthocyanins, the anthochlor pigments are probably related chemically to the anthocyanins. 22 references.

The use of anthochlor as an indicator. *Ibid.* 215–24.—For use as indicators, the flower exts. (cf. preceding abstr.) should contain no H_2SO_4 but a trace of phenol should be added to restrain mold growth. Common flowers which may be used are *Dahlia variabilis*, *Coreopsis lanceolata*, *Cosmos sulphureus*, *Guizotia abyssinica* and *Baeria chrysostoma*. Extensive lists are given of bases giving a red color and acids restoring the yellow color. The exts. are sensitive to very low concns. of H and OH ions. $FeCl_3$ gives a deep-black color. Concd. strong mineral acids give a red color, but the yellow color returns upon dilu. If the exts. turn brown (owing to mold growth or polymerization of the pigment) they still give the same color reactions. Indicator papers may be made, but should be stored in the dark. Dahlia ext. becomes red above 50°. Chem. compn. of anthochlor pigments is reviewed. 12 references. W. C. Tobie

Estimation and occurrence of keto acids in green plants. Artturi I. Virtanen, A. A. Arhimo and Heikki Suomalainen. *Nature* **144**, 597 (1939); cf. *C. A.* **33**, 6911[2].—The method described for detn. of keto acids in plants is based on the formation of 2,4-dinitrophenylhydrazone and its reduction with Na amalgam in alc. soln. to amino acids corresponding to the keto acids. In this way ketoglutaric acid, oxalacetic acid and pyruvic acid have been detd. in plants. E. D. Walter

Effect of ethylene on Magnifera indica. B. K. Kar and H. N. Banerjee. *Nature* **144**, 597–8 (1939).—The effect of different concns. of C_2H_4 on *Magnifera indica* is more pronounced in the pre-climacteric stage of the developing fruit than in the post-climacteric phase. The effect is seen in the rapid increase in the respiration rate, strong hydrolysis of starch, increased concn of total and reducing sugars and decrease in titratable acidity and alc.-insol. residue. The action of C_2H_4 seems to be of a respiratory nature, and is dependent on the available substrate, which depends on the stage of the maturity of the fruit. E. D. Walter

Coloring matter of the yellow flowers of Thevetia nerifolia (Apocyanaceae). R. D. Desai and Zafaruddin Ahmad. *Proc. Natl. Inst. Sci. India* **5**, 261–2 (1939).—The yellow flowers of *Thevetia nerifolia* (yellow oleander) contain 2 glucosides; hydrolysis gives a small quantity of an amorphous brown powder; it does not m. at 360°. The 2nd product is a *4'-Me ether* (?) of quercetin, yellow, m. 260° (*tetra-Ac deriv.*, pale yellow, m. 165°); concd. H_2SO_4 gives a pale-yellow soln. with an intense green fluorescence; $FeCl_3$ gives a green-black color. Demethylation gives quercetin. C. J. West

Changes in the photosynthetic activity of plants during their growth and development (Katunskiĭ) **15**. Effect of Co compds. on the Co content of supplementary fodder crops (Kidson, Maunsell) **15**. Report of the imperial agricultural chemist [on anthocyanin pigments in the rind of sugar canes] (Nath) **15**.

E —NUTRITION

PHILIP B. HAWK

Vitamin K. Henrik Dam. *Nord. Med.* **3**, 2375–9 (1939). A review of the problems concerning vitamin K. V. Aschehoug

A case of sprue treated with vitamin K. Hans Hult. *Nord. Med.* **3**, 2428–30 (1939).—A case of sprue was complicated by a K avitaminosis, which rapidly disappeared after vitamin K treatment. V. Aschehoug

Investigations on the transformation of carotene to vitamin A in the liver of rats, especially concerning the velocity of the process. Torben K. With. *Nord. Med.* **3**, 2901–3 (1939).—Expts. were carried out on rats which were fed carotene oil contg. 3000 I. U. per g. per rat, and killed after different intervals of time. The livers were analyzed and the results show that the transformation of carotene to vitamin A takes place almost entirely in the livers. This process begins after 2 hrs. Similar expts. with vitamin A show that after ½ to 1 hr. vitamin A could be identified in the liver. V. Aschehoug

Examinations of colloidal solutions of vitamin A and carotenoids. Torben K. With. *Nord. Med.* **3**, 2903–6 (1939). The prepn., analysis and keeping quality of colloidal solns. of vitamin A and carotenoids are discussed. V. Aschehoug

The effect of vitamin A given parenterally. Torben K. With. *Nord. Med.* **3**, 2906–8 (1939).—Expts. on rats, guinea pigs and chicks show that subcutaneous and intramuscular injections of vitamin A or carotene (dissolved in oil or in colloidal aq. soln.) were less effective than when the same amts. were given *per os*. V. Aschehoug

Silver foxes need the antigray hair vitamin. Gulbrand Lunde and Hans Kringstad. *Norsk Pelsdyrblad* **13**, 500–4 (1939).—Expts. carried out on silver foxes show that for the normal development of the pelt the antigray hair

vitamin called B_x belonging to the vitamin B complex is needed. This vitamin is also necessary for rats (cf. *C. A.* **32**, 5456[9]). While liver of mammals is the richest source of this vitamin, yeast also contains the antigray hair vitamin, but in varying amts. Fish liver is a fair source. Meat of mammals, fish flesh, wheat germ, maize and whale flesh meal are poor sources. V. Aschehoug

Vitamin C and blood changes. Raffaele D'Alessandro. *Minerva med.* **1939**, II, 273–8.—Ascorbic acid injected subcutaneously into normal rabbits (0.2 g. daily for 12 days) increased slightly the no. of red cells while that of white cells remained the same. When ascorbic acid was injected into rabbits which had been bled to produce a secondary anemia, the increase of red cells was greater, the increase being accompanied by the appearance of reticulocytes and nucleated red cells. E. S. G. B.

Vitamin C determinations in health and in chronic polyarthritis, scurvy and leucemia. G. A. K. von dem Borne. *Nederland. Tijdschr. Geneeskunde* **83**, IV, 5265–73(1939).—The normal vitamin C content of the blood is assumed to be 8 mg. per l. Satn. should occur after 8 oral doses of 300 mg. In spring small shortages are repeatedly encountered pointing to a seasonal shortness in vitamin C. In chronic polyarthritis vitamin C is on the normal level. In scurvy the level is below 4 mg. per l., in some cases down to less than 2 mg. per l. In leucemia vitamin C is above the normal level, probably because of the high vitamin content of the leucocytes. R. Beutner

The effect of the ingestion of irradiated yeast, molds and ergosterol on the antirachitic potency of ewe milk. Wm. G. Kirk. *Iowa State Coll. J. Sci.* **13**, 235(1939).—Summer feeding conditions did not increase the content of vitamin D in the milk of nursing ewes, but the addn. of irradiated ergosterol increased the antirachitic activity considerably and the addn. of irradiated yeast and molds produced twice the effect of equal amts. of ergosterol. The potency decreased rapidly when supplemental feeding was discontinued. F. E. Brown

Biological assay of feeding stuffs in a basal ration for coccidium-growth-promoting substance. III. Dried fish meal, alfalfa meal and white wheat flour. Elery R. Becker and Philip C. Waters. *Iowa State Coll. J. Sci.* **13**, 213–7(1939), cf. *C. A.* **32**, 5037[6].—Addn. of these substances to a basal ration does not produce the same proportional change in the weights of the rats as it does in the no. of oöcysts produced in the rats. This confirms the findings based on expts. with 11 other feeding stuffs. F. E. Brown

Vitamins and vitamin preparations in small animal practice. M. L. Morris and W. C. Russell. *J. Am. Vet. Med. Assoc.* **95**, 555–65(1939).—A review with 30 references. Rachel Brown

Availability of serum fat. I. Availability of unsaturated fat and of fat in general, in healthy young adults. J. W. Duyff. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 190–2(1939). The mean values for total fat and for fat in the cold ether ext. of oxalate plasma from 16 healthy 20–22 yr. old males after 10 hrs. fast were, resp., 515 and 65 mg./100 cc. Hence the mean availability ratio was 8.5. The mean BP values (100 cc.) for total ext. and for cold ether ext. were, resp., 3.37 and 0.36, with a mean availability ratio of 10.4. **II. Influence of fat ingestion on availability in young adults.** *Ibid.* 192–5.—Alimentary hyperlipemia in the above-mentioned subjects reached a max. 4 hrs. after ingestion of 250 g. of cream; after 8 hrs. fasting values were nearly regained. E. Curzon

The biological activity of synthetic *dl*-α-tocopherol and of natural *d*-α-tocopherol (vitamin E). Chr. Engel and A. Emmerie. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 197(1939).—The biol. activity of these 2 substances, compared on vitamin E-deficient female rats, was nearly the same. E. Curzon

Experimental hyperchromic anemia in rats. G. A. Overbeek and J. B. M. Vismans. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 206–7(1939). Hyperchromic anemia was produced in 6 out of 36 thyroidectomized rats after a few weeks on a diet free from "extrinsic factor." Remnants of thyroid gland were found in almost all animals who did not become anemic. E. Curzon

The spleen and the level of plasma iron. A. Ballière. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 225–7(1939).—See *C. A.* **33**, 8736[3]. E. Curzon

Edema due to dietary deficiencies in Morocco. E. Pouhin. *Bull. soc. path. exotique* **32**, 769–79(1939). E. Curzon

Amount and digestibility of the bacterial protein produced by zymogenic symbiosis in the paunch of ruminants on the basis of slaughtering results. Edgar Studt. *Z. Tierzucht. Zuchtungsbiol.* **44**, 253–61(1939). In the paunch of sheep slaughtered after fasting 18 hrs. and previously fed a diet in which molasses amides or ammonia supplied all the N except for a small amt. in straw protein, 8–14 times as much protein (75% digestible) was found as was in the daily ration. The dry matter found in the paunch amounted to only about twice the straw in the daily ration. The amt. of bacterial protein increases simultaneously with the wt. of the paunch contents. E. Curzon

The influence of ascorbic acid on the behavior of the organism at rest. A. R. Ratsimamanga. *Travail humain* **7**, 303–21(1939).—In guinea pigs on a diet deficient in ascorbic acid, liver and muscle glycogen decreases to 1/5 normal, adrenal ascorbic acid to 1/10 and phosphocreatine to about 1/2 normal, while muscle and blood lactate tend to increase. The rates of return to normal are roughly proportional to concn. of ascorbic acid added to the diet. D. B. Dill

Utilization of energy of wheat products by chickens. G. S. Fraps and E. C. Carlyle. *J. Nutrition* **18**, 385–98(1939); cf. *C. A.* **33**, 7851[4].—The feeds under comparison were fed as 1/3 of a ration otherwise const. in compn. for a 3-weeks test. With the cornmeal ration as standard, 3 tests were made with patent flour and low-grade flour, 2 with wheat bran and 1 with cornmeal. Productive energies were as follows: cornmeal 225 per 100 g., patent flour 188, low-grade flour 187, wheat brown shorts 86 and wheat bran 61. The relative productive energy values of effective digestible nutrients averaged, with cornmeal 278, patent flour 236, low-grade flour 251, wheat brown shorts 179 and wheat bran 173. The relative productive energy values of metabolizable energy were with cornmeal 61, patent flour 53, low-grade flour 57, wheat brown shorts 41 and wheat bran 41. When measured by gains of energy in protein and fat of growing chicks, neither the total nutrients, the digestible nutrients nor the metabolizable energy are correct measures of the feeding values of cornmeal, wheat flour, wheat brown shorts and wheat bran. C. R. Fellers
